Cursors and prepared statements in procedures: All cursors opened in the called procedure that are not result set cursors are closed, and all statements prepared in the called procedure are destroyed when the procedure ends. CLOSQLCR(*ENDACTGRP) can be used to keep cursors open when the procedure ends. For more information, see [“SET OPTION” on page 1303](#).

Result sets from procedures: There are three ways to return result sets from a procedure:

- If a SET RESULT SETS statement is executed in the procedure, the last SET RESULT SETS statement executed in the procedure identifies the result sets. The result sets are returned in the order specified on the SET RESULT SETS statement.
- If a SET RESULT SETS statement is not executed in the procedure,
 - If no cursors have specified a WITH RETURN clause, each cursor that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.
 - If any cursors have specified a WITH RETURN clause, each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

If a cursor result set references an SQL array type, an error will be returned if the array reference would cause incorrect results when processing the result set.

Locks in procedures: All locks that have been acquired in the called procedure are retained until the end of the unit of work.

Errors from procedures: A procedure can return errors (or warnings) using the SQLSTATE like other SQL statements. Applications should be aware of the possible SQLSTATEs that can be expected when invoking a procedure. The possible SQLSTATEs depend on how the procedure is coded. Procedures may also return SQLSTATEs such as those that begin with '38' or '39' if the database manager encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that may result from issuing a CALL statement.

Nesting CALL statements: A program that is executing as a procedure, a user-defined function, or a trigger can issue a CALL statement. When a procedure, user-defined function, or trigger calls a procedure, user-defined function, or trigger, the call is considered to be nested. There is no limit on how many levels procedures and functions can be nested, but triggers can only be nested up to 200 levels deep.

If a procedure returns any query result sets, the result sets are returned to the caller of the procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, if a client program calls procedure PROCA, which in turn calls procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets.

When an SQL or an external procedure is called, an attribute is set for SQL data-access that was defined when the procedure was created. The possible values for the attribute are:

```
NONE  
CONTAINS  
READS  
MODIFIES
```

If a second procedure is invoked within the execution of the current procedure, an error is issued if:

- The invoked procedure possibly contains SQL and the invoking procedure does not allow SQL
- The invoked procedure reads SQL data and the invoking procedure does not allow reading SQL data
- The invoked procedure modifies SQL data and the invoking procedure does not allow modifying SQL data

REXX procedures: If the external procedure to be called is a REXX procedure, then the procedure must be declared using the CREATE PROCEDURE or DECLARE PROCEDURE statement.

Variables cannot be used in the CALL statement within a REXX procedure. Instead, the CALL must be the object of a PREPARE and EXECUTE using parameter markers.

Multiple SQL descriptors on CALL: If SQL descriptors are specified on CALL and a procedure has IN or INOUT parameters and OUT or INOUT parameters, two descriptors must be specified. The number of variables that must be allocated in the SQL descriptors depends on how the SQL descriptor attributes are set and the number of each type of parameter.

- If the input SQL descriptor attributes were set using DESCRIBE INPUT and the output SQL descriptor attributes were set using DESCRIBE (OUTPUT), the SQL descriptors will have attributes that match the actual procedure definition at the current server prior to calling the procedure. In this case, the output SQL descriptor will contain one variable for each OUT and INOUT parameter. Likewise, the input SQL descriptor will contain one variable for each IN and INOUT parameter.

This is the recommended technique for specifying multiple SQL descriptors on a CALL statement.

- Otherwise, the actual procedure definition at the current server is unknown prior to calling the procedure, so each parameter is assumed to be INOUT at the time the procedure is called. This means that both SQL descriptors must be specified, and since each parameter is assumed to be INOUT, they must have the same number of variables and the TYPE, DATETIME_INTERVAL_CODE, LENGTH,

DB2_CCSID, PRECISION, and SCALE of each variable in the output SQL descriptor must be exactly the same as the corresponding variable in the input SQL descriptor. Otherwise, an error is returned.

If multiple SQL descriptors are specified, the DATA or INDICATOR items associated with any INOUT parameters in the input SQL descriptor may also be modified when the procedure is called. Thus, a SET DESCRIPTOR may be necessary to reset the DATA and INDICATOR items for such an input SQL descriptor prior to its use in another SQL statement.

Examples

Example 1: Call procedure PGM1 and pass two parameters.

```
CALL PGM1 (:hv1,:hv2)
```

Example 2: In C, invoke a procedure called SALARY_PROC using the SQLDA named INOUT_SQLDA.

```
struct sqlda *INOUT_SQLDA;  
/* Setup code for SQLDA variables goes here */  
CALL SALARY_PROC USING DESCRIPTOR :*INOUT_SQLDA;
```

Example 3: A Java procedure is defined in the database using the following statement:

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,  
                                OUT COST DECIMAL(7,2),  
                                OUT QUANTITY INTEGER)  
LANGUAGE JAVA PARAMETER STYLE JAVA  
EXTERNAL NAME 'parts!onhand';
```

A Java application calls this procedure on the connection context 'ctx' using the following code fragment:

```
...  
int      variable1;  
BigDecimal variable2;  
Integer   variable3;  
...  
#sql [ctx] {CALL PARTS_ON_HAND(:IN variable1, :OUT variable2, :OUT variable3)};  
...
```

This application code fragment will invoke the Java method *onhand* in class *parts* since the *procedure-name* specified on the CALL statement is found in the database and has the external name 'parts!onhand'.

Example 4: Call procedure PGM2 on relational database BRANCHRDB2 and pass one parameter.

```
CALL BRANCHRDB2.SCHEMA3.PGM2 (:hv1)
```

Example 5: Assume the following procedure exists.

```
CREATE PROCEDURE update_order(  
    IN IN_POID BIGINT,  
    IN IN_CUSTID BIGINT DEFAULT GLOBAL_CUST_ID,  
    IN NEW_STATUS VARCHAR(10) DEFAULT NULL,  
    IN NEW_ORDERDATE DATE DEFAULT NULL,  
    IN NEW_COMMENTS VARCHAR(1000)DEFAULT NULL)...
```

Also assume that the global variable GLOBAL_CUST_ID is set to the value 1002. Call the procedure to change the status of order 5000 for customer 1002 to 'Shipped'. Leave the rest of the order data as it is by allowing the rest of the arguments to default to the null value.

```
CALL update_order (5000, NEW_STATUS => 'Shipped')
```

The customer with ID 1001 has called and indicated that they received their shipment for purchase order 5002 and are satisfied. Update their order.

```
CALL update_order (5002,  
                  IN_CUSTID => 1001,
```

```
    NEW_STATUS => 'Received',
    NEW_COMMENTS => 'Customer satisfied with the order.')
```

CLOSE

The CLOSE statement closes a cursor. If a result table was created when the cursor was opened, that table is destroyed.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required. See “[DECLARE CURSOR](#)” on page 1037 for the authorization required to use a cursor.

Syntax

►► CLOSE — *cursor-name* ►►

Description

cursor-name

Identifies the cursor to be closed. The *cursor-name* must identify a declared cursor as explained in the DECLARE CURSOR statement. When the CLOSE statement is executed, the cursor must be in the open state.

Notes

Implicit cursor close: All cursors in a program are in the closed state when:

- The program is called.
 - If CLOSQLCSR(*ENDPGM) is specified, all cursors are in the closed state each time the program is called.
 - If CLOSQLCSR(*ENDSQL) is specified, all cursors are in the closed state only the first time the program is called as long as one SQL program remains on the call stack.
 - If CLOSQLCSR(*ENDJOB) is specified, all cursors are in the closed state only the first time the program is called in the job.
 - If CLOSQLCSR(*ENDMOD) is specified, all cursors are in the closed state each time the module is initiated.
 - If CLOSQLCSR(*ENDACTGRP) is specified, all cursors are in the closed state the first time the module in the program is initiated within the activation group.
- A program starts a new unit of work by executing a COMMIT or ROLLBACK statement without a HOLD option. Cursors declared with the HOLD option are not closed by a COMMIT statement.

Note: The Db2 for i database manager will open files in order to implement queries. The closing of the files can be separate from the SQL CLOSE statement. For more information, see [SQL Programming](#).

Close cursors for performance: Explicitly closing cursors as soon as possible can improve performance.

Procedure considerations: Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see “[CALL](#)” on page 772.

Example

In a COBOL program, use the cursor C1 to fetch the values from the first four columns of the EMPPROJECT table a row at a time and put them in the following host variables:

- EMP (CHAR(6))
- PRJ (CHAR(6))
- ACT (SMALLINT)
- TIM (DECIMAL(5,2))

Finally, close the cursor.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.  
    77  EMP          PIC X(6).  
    77  PRJ          PIC X(6).  
    77  ACT          PIC S9(4) BINARY.  
    77  TIM          PIC S9(3)V9(2) PACKED-DECIMAL.  
EXEC SQL END DECLARE SECTION END-EXEC.  
. . .  
EXEC SQL DECLARE C1 CURSOR FOR  
      SELECT EMPNO, PROJNO, ACTNO, EMPTIME  
      FROM EMPPROJECT           END-EXEC.  
EXEC SQL OPEN C1 END-EXEC.  
EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM END-EXEC.  
IF SQLSTATE = '02000'  
  PERFORM DATA-NOT-FOUND  
ELSE  
  PERFORM GET-REST-OF-ACTIVITY UNTIL SQLSTATE IS NOT EQUAL TO '00000'.  
EXEC SQL CLOSE C1 END-EXEC.  
GET-REST-OF-ACTIVITY  
EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM END-EXEC.  
. . .
```

COMMENT

The COMMENT statement adds or replaces comments in the catalog descriptions of various database objects.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

To comment on a table, view, alias, column, type, package, sequence, variable, or XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the table, view, alias, type, package, sequence, variable, or XSR object in the statement,
 - The ALTER privilege on the table, view, alias, type, package, sequence, variable, or XSR object, and
 - The USAGE privilege on the schema that contains the table, view, alias, index, type, package, sequence, variable, or XSR object
- Administrative authority

To comment on a constraint or trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the subject table of the constraint or trigger in the statement:
 - The ALTER privilege on the subject table, and
 - The USAGE privilege on the schema that contains the subject table
- Database administrator authority

To comment on an index, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the index identified in the statement,
 - The system authority *OBJALTER on the index, and
 - The USAGE privilege on the schema containing the index.
- Administrative authority

To comment on a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSFUNCS and SYSROUTINES catalog view and table:
 - The UPDATE privilege on SYSROUTINES,
 - The system authority *OBJOPR on SYSFUNCS, and
 - The USAGE privilege on schema QSYS2
- Administrative authority

To comment on a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS and SYSROUTINES catalog view and table:
 - The UPDATE privilege on SYSROUTINES,
 - The system authority *OBJOPR on SYSPROCS, and
 - The USAGE privilege on schema QSYS2
- Administrative authority

To comment on a parameter or table function return column, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPARMS catalog table:
 - The UPDATE privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Administrative authority

To comment on a mask or permission:

- The authorization ID of the statement must be authorized to the Database Security Administrator function of IBM i. See [“Administrative authority” on page 15](#).

To comment on a sequence, the privileges held by the authorization ID of the statement must also include at least one of the following:

- *USE authority to the Change Data Area (CHGDTAARA), CL command
- Administrative authority

To comment on a variable, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the SYSVARIABLES catalog table:
 - The UPDATE privilege on SYSVARIABLES, and

- The USAGE privilege on schema QSYS2
- Administrative authority

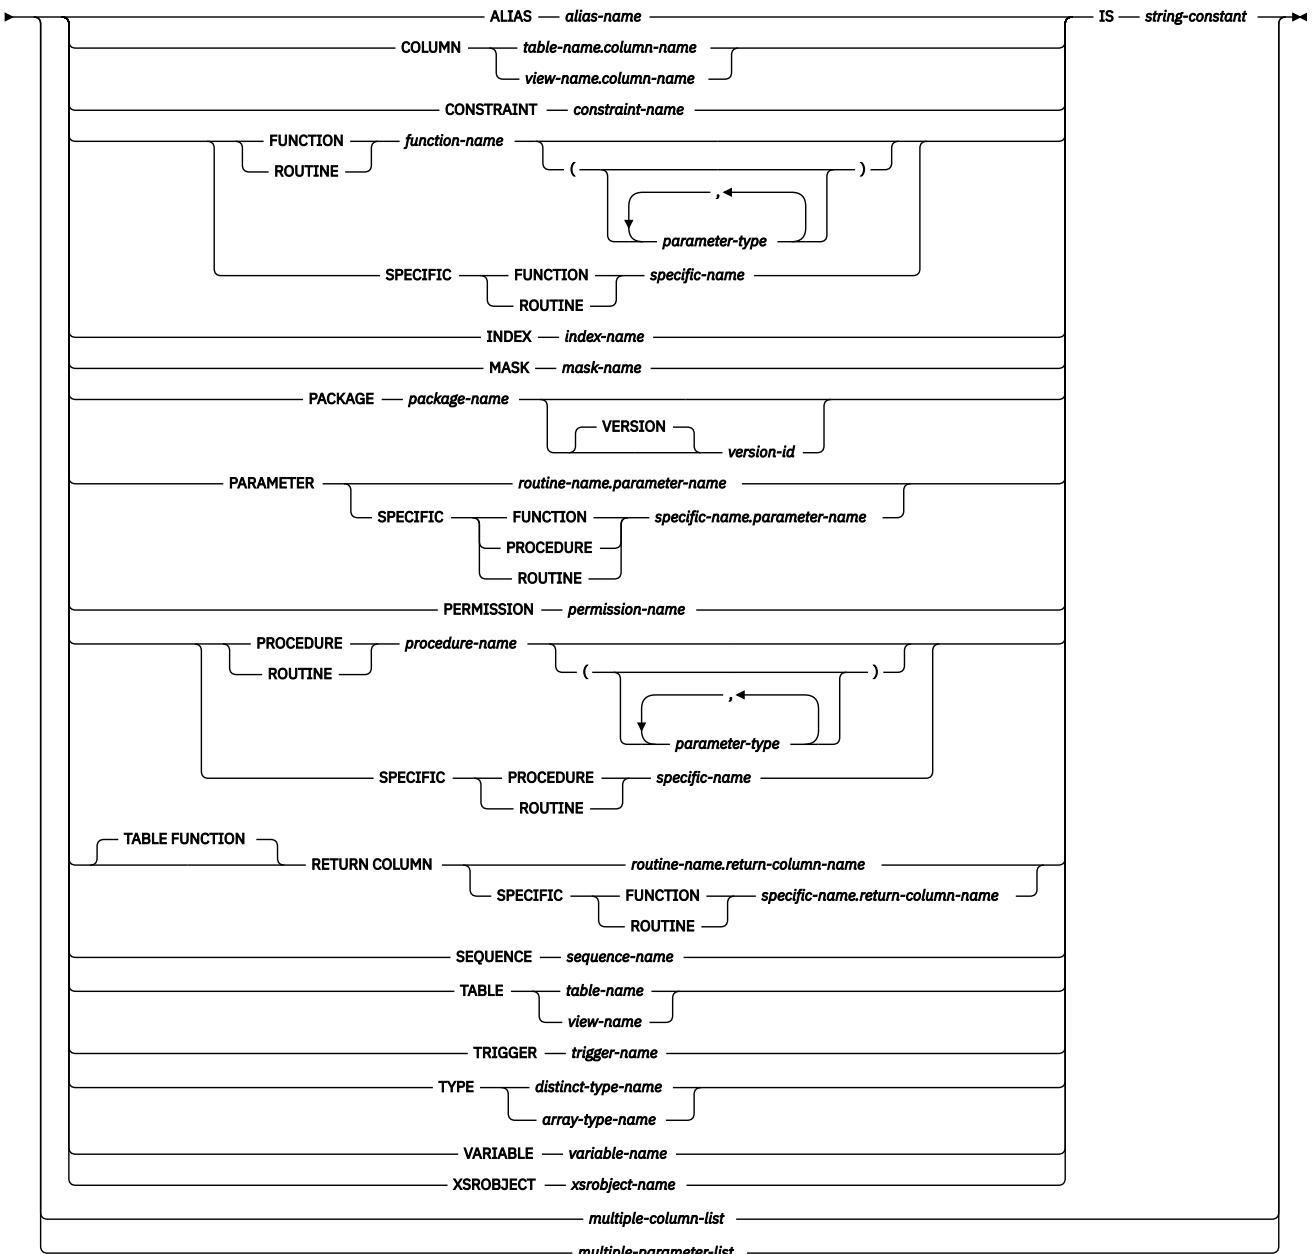

To comment on an XSR object, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the XSROBJECTS catalog table:
 - The UPDATE privilege on XSROBJECTS, and
 - The USAGE privilege on schema QSYS2
- Administrative authority

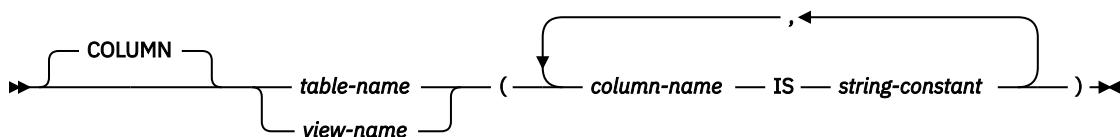

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#), [Corresponding System Authorities When Checking Privileges to a User-defined Type](#), [Corresponding System Authorities When Checking Privileges to a Sequence](#), [Corresponding System Authorities When Checking Privileges to a Variable](#), [Corresponding System Authorities When Checking Privileges to a Package](#), and [Corresponding System Authorities When Checking Privileges to an XSR object](#).

ccsid-clause

►► CCSID — *integer* ►►

Description

ALIAS *alias-name*

Identifies the alias to which the comment applies. The *alias-name* must identify an alias that exists at the current server.

COLUMN

Specifies that a comment will be added to or replaced for a column.

table-name.column-name or view-name.column-name

Identifies the column to which the comment applies. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table. The *column-name* must identify a column of that table or view.

CONSTRAINT

Specifies that a comment will be added to or replaced for a constraint.

constraint-name

Identifies the constraint to which the comment applies. The *constraint-name* must identify a constraint that exists at the current server.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the comment applies. The function must exist at the current server and it must be a user-defined function. The function can be identified by its name, function signature, or specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type, ...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which to comment.

Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must

exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

INDEX *index-name*

Identifies the index to which the comment applies. The *index-name* must identify an index that exists at the current server.

MASK *mask-name*

Identifies the mask to which the comment applies. The *mask-name* must identify a mask that exists at the current server.

PACKAGE *package-name*

Identifies the package to which the comment applies. The *package-name* must identify a package that exists at the current server.⁸⁶

VERSION *version-id*

version-id is the version identifier that was assigned to the package when it was created. If *version-id* is not specified, a null string is used as the version identifier.

PARAMETER

Specifies that a comment will be added to or replaced for a parameter.

routine-name*.*parameter-name

Identifies the parameter to which the comment applies. The parameter could be for a procedure or a function. The *routine-name* must identify a procedure or function that exists at the current server, and the *parameter-name* must identify a parameter of that procedure or function.

specific-name*.*parameter-name

Identifies the parameter to which the comment applies. The parameter could be for a procedure or a function. The *specific-name* must identify a procedure or function that exists at the current server, and the *parameter-name* must identify a parameter of that procedure or function.

PERMISSION *permission-name*

Identifies the permission to which the comment applies. The *permission-name* must identify a permission that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to which the comment applies. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name* (*parameter-type*, ...)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name* (*parameter-type*, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical

⁸⁶ If the identified package has a *version-id*, the comment is limited to 176 bytes.

concatenation of the data types is used to identify the specific procedure instance which is to be commented on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name* () is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(*parameter-type*, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

RETURN COLUMN

Specifies that a comment will be added to or replaced for a return column of a table function.

routine-name.return-column-name

Identifies the return column to which the comment applies. The return column must be for a table function. The *routine-name* must identify a table function that exists at the current server, and the *return-column-name* must identify a return column of that function.

specific-name.return-column-name

Identifies the return column to which the comment applies. The return column must be for a table function. The *specific-name* must identify a table function that exists at the current server, and the *return-column-name* must identify a return column of that function.

SEQUENCE *sequence-name*

Identifies the sequence to which the comment applies. The *sequence-name* must identify a sequence that exists at the current server.

TABLE *table-name or view-name*

Identifies the table or view to which the comment applies. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TRIGGER *trigger-name*

Identifies the trigger to which the comment applies. The *trigger-name* must identify a trigger that exists at the current server.

TYPE *distinct-type-name or array-type-name*

Identifies the distinct type or array type to which the comment applies. The *distinct-type-name* or *array-type-name* must identify a type that exists at the current server.

VARIABLE *variable-name*

Identifies the variable to which the comment applies. The *variable-name* must identify a variable that exists at the current server.

XSROBJECT *xsrobject-name*

Identifies the XSR object to which the comment applies. The *xsrobject-name* must identify an XSR object that exists at the current server.

IS

Introduces the comment that to be added or replaced.

string-constant

Can be any character-string constant of up to 2000 characters (500 for a sequence).

multiple-column-list

To comment on more than one column in a table or view, specify the table or view name and then, in parenthesis, a list of the form:

```
(column-name IS string-constant,  
 column-name IS string-constant, ... )
```

The column name must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

multiple-parameter-list

To comment on more than one parameter in a procedure or function, specify the procedure name, function name, or specific name, and then, in parenthesis, a list of the form:

```
(parameter-name IS string-constant,  
 parameter-name IS string-constant, ... )
```

The parameter name must not be qualified, each name must identify a parameter of the specified procedure or function, and that procedure or function must exist at the current server.

multiple-return-column-list

To comment on more than one return column in a table function, specify the function name or specific name, and then, in parentheses, a list of the form:

```
(return-column-name IS string-constant,  
 return-column-name IS string-constant, ... )
```

The return column name must not be qualified, each name must identify a return column of the specified table function, and that function must exist at the current server.

Notes

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword PROGRAM can be used as a synonym for PACKAGE.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Examples

Example 1: Insert a comment for the EMPLOYEE table.

```
COMMENT ON TABLE EMPLOYEE
IS 'Reflects first quarter 2000 reorganization'
```

Example 2: Insert a comment for the EMP_VIEW1 view.

```
COMMENT ON TABLE EMP_VIEW1
IS 'View of the EMPLOYEE table without salary information'
```

Example 3: Insert a comment for the EDLEVEL column of the EMPLOYEE table.

```
COMMENT ON COLUMN EMPLOYEE.EDLEVEL
IS 'Highest grade level passed in school'
```

Example 4: Enter comments on two columns in the DEPARTMENT table.

```
COMMENT ON DEPARTMENT
(MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',
ADMDEPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT')
```

Example 5: Insert a comment for the PAYROLL package.

```
COMMENT ON PACKAGE PAYROLL
IS 'This package is used for distributed payroll processing.'
```

COMMIT

The COMMIT statement ends a unit of work and commits the database changes that were made by that unit of work.

Invocation

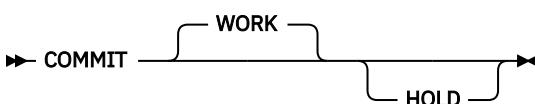

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

COMMIT is not allowed in a trigger if the trigger program and the triggering program run under the same commitment definition. COMMIT is not allowed in a procedure if the procedure is called on a Distributed Unit of Work connection to a remote application server or if the procedure is defined as ATOMIC. COMMIT is not allowed in a function.

Authorization

None required.

Syntax

Description

The COMMIT statement ends the unit of work in which it is executed and starts a new unit of work. It commits all changes made by SQL schema statements (except DROP SCHEMA) and SQL data change statements during the unit of work. For information about SQL schema statements and SQL data change statements see [Chapter 7, “Statements,” on page 655](#).

Connections in the release-pending state are ended.

WORK

COMMIT WORK has the same effect as COMMIT.

HOLD

Specifies a hold on resources. If specified, currently open cursors are not closed whether they are declared with a HOLD option or not. All resources acquired during the unit of work are held. Locks on specific rows and objects implicitly acquired during the unit of work are released.

All implicitly acquired locks are released; except for object level locks required for the cursors that are not closed.

All locators that are not held are released. For more information about held locators, see [“HOLD LOCATOR” on page 1197](#).

Notes

Recommended coding practices: An explicit COMMIT or ROLLBACK statement should be coded at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

An implicit COMMIT or ROLLBACK may be performed under the following circumstances.

- For the default activation group:
 - An implicit COMMIT is not performed when applications that run in the default activation group end. Interactive SQL, Query Manager, and non-ILE programs are examples of programs that run in the default activation group.
 - In order to commit work, you must issue a COMMIT.
- For non-default activation groups when the scope of the commitment definition is to the activation group:
 - If the activation group ends normally, the commitment definition is implicitly committed.
 - If the activation group ends abnormally, the commitment definition is implicitly rolled back.
- Regardless of the type of activation group, if the scope of the commitment definition is the job, an implicit commit is never performed.

Effect of commit: Commit without HOLD causes the following to occur:

- Connections in the release-pending state are ended.

For existing connections:

- all open cursors that were declared with the WITH HOLD clause are preserved and their current position is maintained, although a FETCH statement is required before a Positioned UPDATE or Positioned DELETE statement can be executed.
- all open cursors that were declared without the WITH HOLD clause including any opened under isolation level NC are closed.
- All LOB locators that are not held are freed. Note that this is true even when the locators are associated with LOB values retrieved via a cursor that has the WITH HOLD property.
- All locks acquired by the LOCK TABLE statement are released. All implicitly acquired locks are released, except for those required for the cursors that were not closed.

Row lock limit: A unit of work can include the processing of up to 4 million rows, including rows retrieved during a SELECT or FETCH statement⁸⁷, and rows inserted, deleted, or updated as part of INSERT, DELETE, and UPDATE statements.⁸⁸

Unaffected statements: The commit and rollback operations do not affect the DROP SCHEMA statement, and this statement is not, therefore, allowed in an application program that also specifies COMMIT(*CHG), COMMIT(*CS), COMMIT(*ALL), or COMMIT(*RR).

COMMIT Restrictions: A commit or rollback in a user-defined function in a secondary thread is not allowed.

Commitment definition use: The commitment definition used by SQL is determined as follows:

- If the activation group of the program calling SQL is already using an activation group level commitment definition, then SQL uses that commitment definition.
- If the activation group of the program calling SQL is using the job level commitment definition, then SQL uses the job level commitment definition.
- If the activation group of the program calling SQL is not currently using a commitment definition but the job commitment definition is started, then SQL uses the job commitment definition.
- If the activation group of the program calling SQL is not currently using a commitment definition and the job commitment definition is not started, then SQL implicitly starts a commitment definition. SQL uses the Start Commitment Control (STRCMTCTL) command with:
 - A CMTSCOPE(*ACTGRP) parameter
 - A LCKLVL parameter based on the COMMIT option specified on either the CRTSQLxxx, STRSQL, or RUNSQLSTM commands. In REXX, the LCKLVL parameter is based on the commit option in the SET OPTION statement.

Example

In a C program, transfer a certain amount of commission (COMM) from one employee (EMPNO) to another in the EMPLOYEE table. Subtract the amount from one row and add it to the other. Use the COMMIT statement to ensure that no permanent changes are made to the database until both operations are completed successfully.

```
void main ()  
{  
    EXEC SQL BEGIN DECLARE SECTION;  
    decimal(5,2) AMOUNT;  
    char FROM_EMPNO[7];  
    char TO_EMPNO[7];  
    EXEC SQL END DECLARE SECTION;  
    EXEC SQL INCLUDE SQLCA;  
    EXEC SQL WHENEVER SQLERROR GOTO SQLERR;  
    ...  
    EXEC SQL UPDATE EMPLOYEE  
        SET COMM = COMM - :AMOUNT  
        WHERE EMPNO = :FROM_EMPNO;  
    EXEC SQL UPDATE EMPLOYEE  
        SET COMM = COMM + :AMOUNT  
        WHERE EMPNO = :TO_EMPNO;
```

⁸⁷ This limit also includes:

- Any rows accessed or changed through files opened under commitment control through high-level language file processing
- Any rows deleted, updated, or inserted as a result of a trigger or CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.

⁸⁸ Unless you specified COMMIT(*CHG) or COMMIT(*CS), in which case these rows are not included in this total.

```

FINISHED:
  EXEC SQL COMMIT WORK;
  return;

SQLERR:
  ...
  EXEC SQL WHENEVER SQLERROR CONTINUE; /* continue if error on rollback */
  EXEC SQL ROLLBACK WORK;
  return;
}

```

compound (dynamic)

A compound (dynamic) statement groups other statements together in an executable routine. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

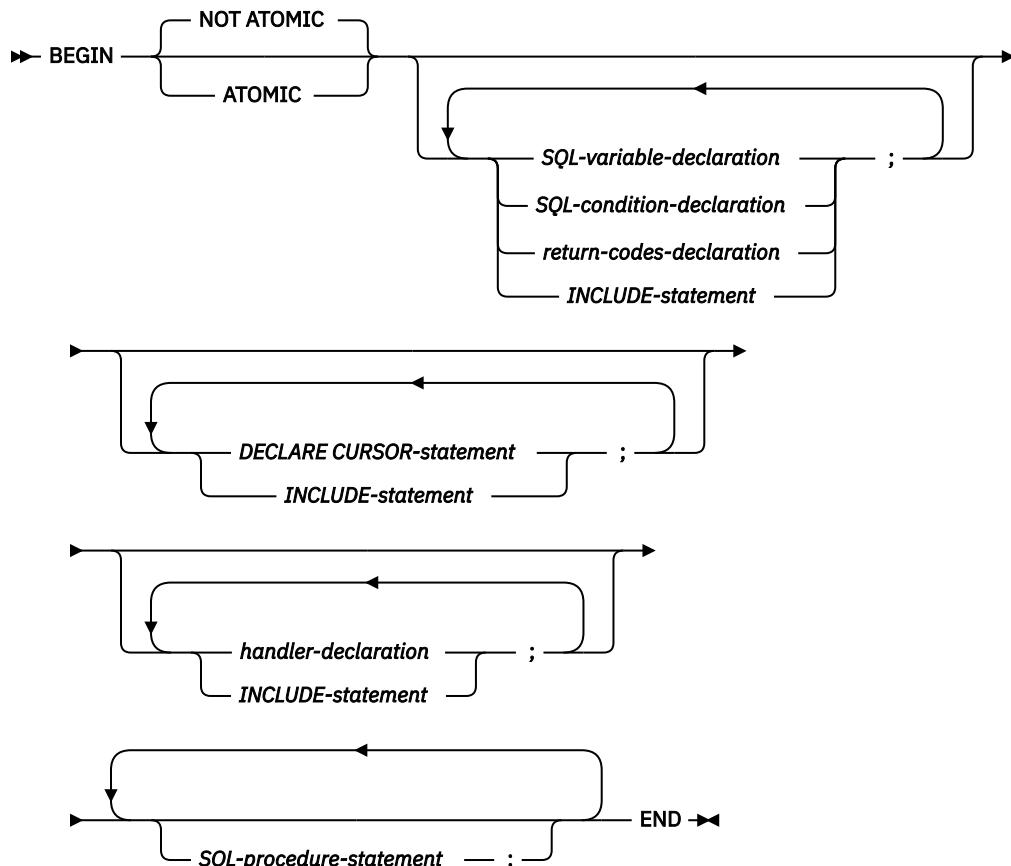

Invocation

This statement can be issued interactively. It is an executable statement that can be dynamically prepared. It cannot be embedded in an application program.

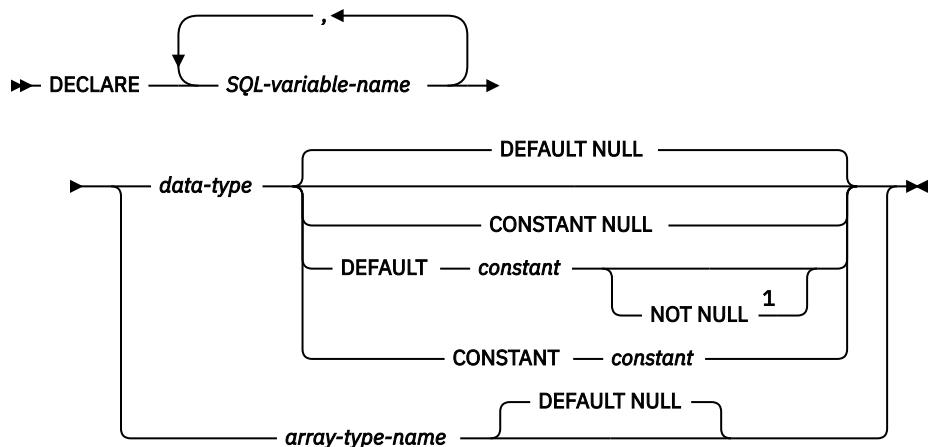

Authorization

The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the compound (dynamic) statement.

Syntax

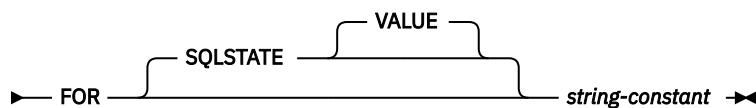

SQL-variable-declaration

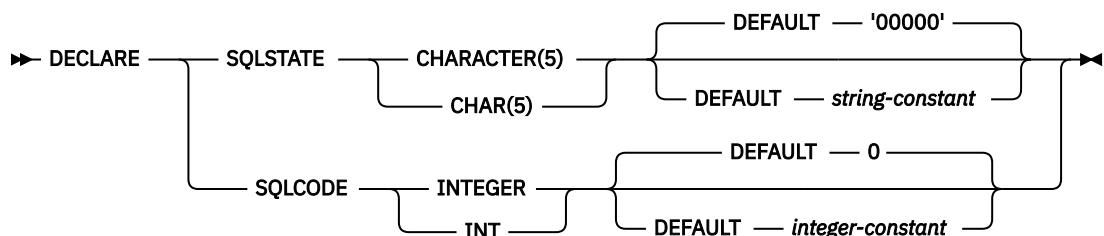

SQL-condition-declaration

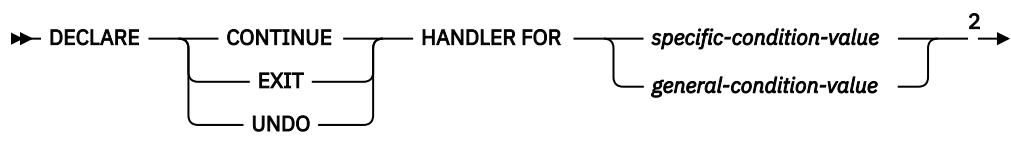

➤ DECLARE — SQL-condition-name — CONDITION ➤

return-codes-declaration

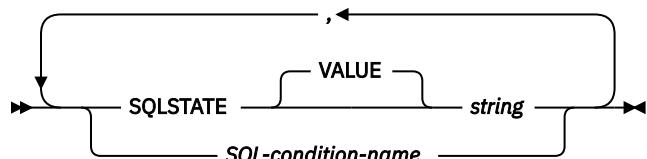

handler-declaration

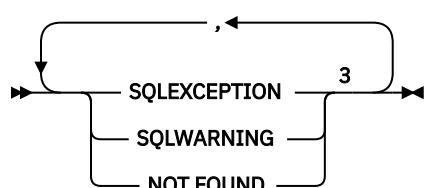

➤ SQL-procedure-statement ➤

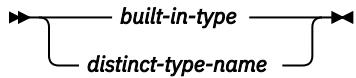

specific-condition-value

general-condition-value

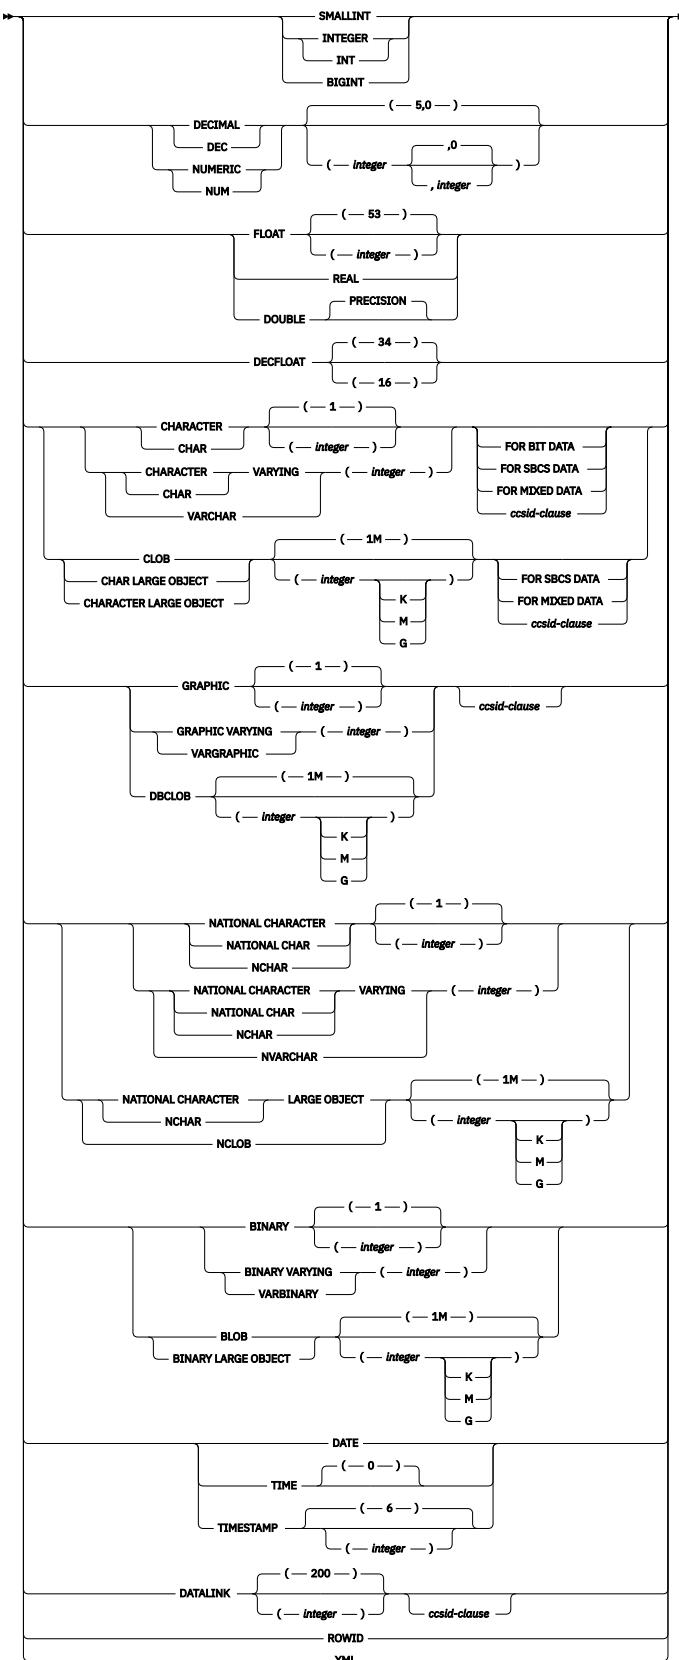

data-type

Notes:

- ¹ The DEFAULT and NOT NULL clauses can be specified in either order.
- ² *specific-condition-value* and *general-condition-value* cannot be specified in the same handler declaration.
- ³ The same clause must not be specified more than once.

built-in-type

ccsid-clause

►► CCSID — *integer* ►►

Description

ATOMIC

ATOMIC indicates that an unhandled exception condition within the compound (dynamic) statement causes the compound statement to be rolled back. If ATOMIC is specified, COMMIT, ROLLBACK (ROLLBACK TO SAVEPOINT may be specified), SET CURRENT DEBUG MODE, SET CURRENT DEGREE, SET CURRENT DECFLOAT ROUNDING MODE, SET CURRENT IMPLICIT XMLPARSE OPTION, SET CURRENT TEMPORAL SYSTEM_TIME, SET PATH, and SET SCHEMA statements cannot be specified in the compound statement.

NOT ATOMIC

NOT ATOMIC indicates that an unhandled exception condition within the compound (dynamic) statement does not cause the compound statement to be rolled back.

SQL-variable-declaration

Declares a variable that is local to the compound (dynamic) statement.

SQL-variable-name

Defines the name of a local SQL variable. The database manager converts all undelimited SQL variable names to uppercase. The name must not be the same as another SQL variable within the same compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement. Do not name SQL variables the same as a column name. See “[References to SQL parameters and SQL variables](#)” on page 1360 for how SQL variable names are resolved when there are columns with the same name involved in a statement. Variable names should not begin with ‘SQL’.

data-type

Specifies the data type of the variable. See “[CREATE TABLE](#)” on page 945 for a description of data type.

If the *data-type* is a graphic string data type, consider specifying CCSID 1200 or 13488 to indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the graphic string variable will be the associated DBCS CCSID for the job.

array-type-name

Specifies that the SQL variable is an array as defined with the CREATE TYPE (Array) statement.

DEFAULT constant or NULL

Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in “[Assignments and comparisons](#)” on page 83. The variable is initialized when the compound (dynamic) statement is invoked. If a default value is not specified, the SQL variable is initialized to NULL. SQL variables of type XML cannot have a default value specified.

NOT NULL

Prevents the SQL variable from containing the NULL value. Omission of NOT NULL implies that the variable can be null. SQL variables of type XML cannot have NOT NULL specified.

CONSTANT constant or NULL

Specifies that the SQL variable has a fixed value that cannot be changed. An SQL variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in “[Assignments and comparisons](#)” on page 83.

SQL-condition-declaration

Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name

Specifies the name of the condition. The condition name must be unique within the compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement.

FOR SQLSTATE string-constant

Specifies the SQLSTATE associated with this condition. The string constant must be specified as 5 characters. The SQLSTATE class (the first 2 characters) must not be ‘00’.

return-codes-declaration

Declares special SQL variables called SQLSTATE and SQLCODE that are set for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty *compound-statement*.

The SQLSTATE and SQLCODE special variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these special variables is ignored by condition handlers. The SQLSTATE and SQLCODE special variables cannot be set to NULL.

DECLARE CURSOR-statement

Declares a cursor in the compound (dynamic) statement. The cursor name must be unique within the compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement.

A *cursor-name* can only be referenced within the compound (dynamic) statement in which it is declared, including any *compound-statements* nested within the compound (dynamic) statement.

Use an OPEN statement to open the cursor, and a FETCH statement to read rows using the cursor. Any open cursor is closed at the end of the compound (dynamic) statement.

For more information about declaring a cursor, refer to “[DECLARE CURSOR](#)” on page 1037.

handler-declaration

Specifies a *handler*, an *SQL-procedure-statement* to execute when an exception or completion condition occurs in the compound (dynamic) statement.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than once, and cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value. For a list of SQLSTATE values as well as more information, see the [SQL messages and codes topic collection](#).

Furthermore, when two or more condition handlers are declared in a compound (dynamic) statement, no two condition handler declarations may specify the same:

- general condition category or
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value.

A condition handler is active for the set of *SQL-procedure-statements* that follow the *handler-declarations* within the compound (dynamic) statement, including any nested *compound-statements*.

A handler for a condition may exist at several levels of nested compound statements. For example, assume that compound (dynamic) statement *n1* contains another compound statement *n2* which contains another compound statement *n3*. When an exception condition occurs within *n3*, any active handlers within *n3* are first allowed to handle the condition. If no appropriate handler exists in *n3*, then the condition is signaled to *n2* and the active handlers within *n2* may handle the condition. If no appropriate handler exists in *n2*, then the condition is signaled to *n1* and the active handlers within *n1* may handle the condition. If no appropriate handler exists in *n1*, the condition is considered unhandled.

There are three types of condition handlers:

CONTINUE

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement following the one that raised the exception. If the error occurs

while executing a comparison as in an IF, CASE, FOR, WHILE, or REPEAT, control returns to the statement following the corresponding END IF, END CASE, END FOR, END WHILE, or END REPEAT.

EXIT

Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound (dynamic) statement.

UNDO

Specifies that when the condition handler is activated changes made by the compound (dynamic) statement are rolled back. When the handler completes successfully, control is returned to the end of the compound (dynamic) statement. If UNDO is specified, then ATOMIC must be specified.

The conditions under which the handler is activated are:

SQLSTATE string

Specifies that the handler is invoked when the specific SQLSTATE occurs. The SQLSTATE class (the first 2 characters) must not be '00'.

SQL-condition-name

Specifies that the handler is invoked when the specific SQLSTATE associated with the condition name occurs. The *SQL-condition-name* must be previously defined in a *SQL-condition-declaration*.

SQLEXCEPTION

Specifies that the handler is invoked when an exception condition occurs. An exception condition is represented by an SQLSTATE value where the first two characters are not '00', '01', or '02'.

SQLWARNING

Specifies that the handler is invoked when a warning condition occurs. A warning condition is represented by an SQLSTATE value where the first two characters are '01'.

NOT FOUND

Specifies that the handler is invoked when a NOT FOUND condition occurs. A NOT FOUND condition is represented by an SQLSTATE value where the first two characters are '02'.

SQL-procedure-statement

An SQL statement or SQL control statement as defined in “[SQL-procedure-statement](#)” on page 1363. The SET RESULT SETS and SET SESSION AUTHORIZATION SQL statements are not allowed.

Notes

Compound (dynamic) content: See “[SQL control statements](#)” on page 1359 for more information on the constructs that can be used in a compound (dynamic) statement.

Nesting compound statements: *Compound-statements* can be nested within a compound (dynamic) statement. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in the compound (dynamic) statement. This can simplify the processing done for each *SQL-procedure-statement*. Support for nested compound statements enables the use of a compound statement within the declaration of a condition handler.

Compound (dynamic) statement execution: When a compound (dynamic) statement is dynamically prepared and executed, the statements within the compound statement are processed as static statements. A temporary program that embeds the statements for the compound statement is created and then executed. The program name is QTEMP.QCMPDnnnnn, where nnnnn is a unique number for the job.

CURRENT PATH and CURRENT SCHEMA: The current schema and current path apply to the prepared and executed compound (dynamic) statement. Any change to these special registers within the compound statement does not affect subsequent resolution of statements within the same compound statement. For example:

```
SET SCHEMA prodlib;
SET stmt = 'BEGIN SET SCHEMA datalib;  INSERT INTO test_table VALUES(1);  END';
PREPARE compound_stmt FROM stmt;
EXECUTE compound_stmt;
```

When the compound statement `compound_stmt` is prepared and executed, the `INSERT` will resolve to `PRODLIB.TEST_TABLE`, not `DATALIB.TEST_TABLE`.

Most end user SQL script interfaces use dynamic SQL to execute SQL statements. For example, executing the following two statements in IBM i Navigator's Run SQL Scripts is logically equivalent to the above example. The `INSERT` will resolve to `PRODLIB.TEST_TABLE`, not `DATALIB.TEST_TABLE`.

```
SET SCHEMA prodlib;
BEGIN
  SET SCHEMA datalib;
  INSERT INTO test_table VALUES(1);
END;
```

Condition handlers: Condition handlers in a compound (dynamic) statement are similar to `WHENEVER` statements used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as a result of an exception, warning, or not found condition that is returned by the database manager for the processing of an SQL statement, or the activating condition can be the result of a `SIGNAL` or `RESIGNAL` statement issued within the routine body.

A condition handler is declared within a compound (dynamic) statement, and it is active for the set of *SQL-procedure-statements* that follow all of the condition handler declarations within the compound (dynamic) statement. To be more specific, the scope of a condition handler declaration `H` is the list of *SQL-procedure-statements* that follows the condition handler declarations contained within the compound (dynamic) statement in which `H` appears. This means that the scope of `H` does not include the statements contained in the body of the condition handler `H`, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers `H1` and `H2` declared in the same compound (dynamic) statement, `H1` will not handle conditions arising in the body of `H2`, and `H2` will not handle conditions arising in the body of `H1`.

The declaration of a condition handler specifies the condition that activates it, the type of the condition handler (`CONTINUE`, `EXIT`, or `UNDO`), and the handler action. The type of the condition handler determines where control is returned to after successful completion of the handler action.

Condition handler activation: When a condition other than successful completion occurs in the processing of an *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a compound (dynamic) statement with nested *compound-statements*, condition handlers that could handle a specific condition may exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at that nesting level could handle the condition, the condition handler that is activated is the most appropriate handler declared in that compound statement.

The most appropriate handler is a handler that is defined in the compound statement which most closely matches the `SQLSTATE` of the exception or completion condition.

For example, if the innermost compound statement declares a specific handler for `SQLSTATE 22001` as well as a handler for `SQLEXCEPTION`, the specific handler for `SQLSTATE 22001` is the most appropriate handler when an `SQLSTATE 22001` is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (`CONTINUE`, `EXIT`, or `UNDO` handler) determines where control is returned. Additionally, the `SQLSTATE` and `SQLCODE` SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully, and an appropriate handler exists for the condition encountered in the handler action, that condition handler is activated. Otherwise, the condition encountered within the condition handler is unhandled.

Unhandled conditions: If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the compound statement containing the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

Considerations for using SIGNAL or RESIGNAL statements with nested compound statements:

If an *SQL-procedure-statement* specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound (dynamic) statement terminates with the specified exception. This happens even if this condition handler or another condition handler in the same compound (dynamic) statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a *compound-statement* is nested in a compound (dynamic) statement, condition handlers in the compound (dynamic) statement may handle the exception from within the *compound-statement* because those condition handlers are within the scope of the exception.

Null values in SQL variables: If the value of an SQL variable is null and it is used in an SQL statement (such as CONNECT or DESCRIBE) that does not allow an indicator variable, an error is returned.

Uncommitted changes: Any uncommitted transactional work is scoped to the activation group of the connection in which the dynamic compound statement is run.

Effect on open cursors: Upon exit from the compound (dynamic) statement for any reason, all open cursors that are declared in that compound statement are closed.

Considerations for SQLSTATE and SQLCODE SQL variables: The compound (dynamic) statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within that compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE variables were not changed within the compound (dynamic) statement, they contain the same values as when the compound (dynamic) statement was invoked.

CONNECT (type 1)

The CONNECT (type 1) statement connects an activation group within an application process to the identified application server using the rules for remote unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*RUW) was specified on the CRTSQLxxx command.

Differences between the two types of statements are described in “[CONNECT \(type 1\) and CONNECT \(type 2\) differences](#)” on page 1429. Refer to “[Application-directed distributed unit of work](#)” on page 38 for more information about connection states.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in [Distributed Database Programming](#)).

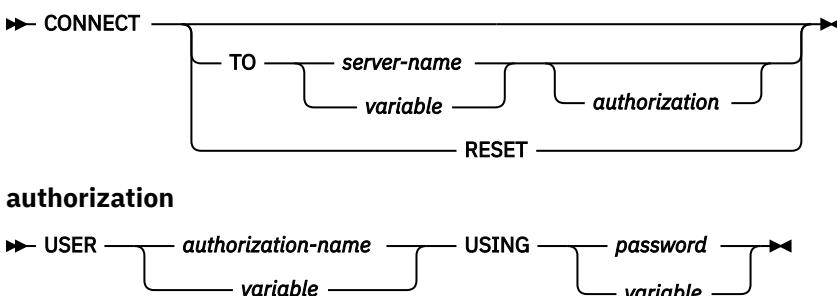

If the application server is Db2 for i, the user profile of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

- User is specified. In this case, the USER clause must specify a valid user profile on the application server system.
- TCP/IP is used with a server authorization entry for the application server. In this case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

TO *server-name* or *variable*

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory and the activation group must be in the connectable state.

If the *server-name* is a local relational database and an *authorization-name* is specified, it must be the user of the job. If the specified *authorization-name* is different than the user of the job, an error occurs and the application is left in the unconnected state.

USER *authorization-name* or *variable*

Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a *variable* is specified,

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.

- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

USING *password or variable*

Identifies the password that will be used to connect to the application server.

If *password* is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a *variable* is specified,

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.

RESET

CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.

CONNECT with no operand

This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).

Notes

Successful connection: If the CONNECT statement is successful:

- All open cursors are closed, all prepared statements are destroyed, and all locks are released from the current connection.
- The activation group is disconnected from all current and dormant connections, if any, and connected to the identified application server.
- The name of the application server is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the *connection-information-items* in the SQL Diagnostics Area.
- Information about the application server is also placed in the SQLERRP and SQLERRD(4) fields of the SQLCA. If the application server is an IBM relational database product, the information in the SQLERRP field has the form *pppvrrm*, where:
 - *ppp* identifies the product as follows:
 - ARI for Db2 for VM and VSE
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for all other Db2 products
 - *vv* is a two-digit version identifier such as '09'
 - *rr* is a two-digit release identifier such as '01'
 - *m* is a one-character modification level such as '0'

For example, if the application server is Version 9 of Db2 for z/OS, the value of SQLERRP is 'DSN09010'.

The SQLERRD(4) field of the SQLCA contains values indicating whether the application server allows committable updates to be performed. For a CONNECT (type 1) statement SQLERRD(4) will always

contain the value 1. The value 1 indicates that committable updates can be performed, and the connection:

- Uses an unprotected conversation⁸⁹, or
 - Is a connection to an application requester driver program using the *RUW connection method, or
 - Is a local connection using the *RUW connection method.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#)

Unsuccessful connection: If the CONNECT statement is unsuccessful, the DB2_MODULE_DETECTING_ERROR condition information item in the SQL Diagnostics Area (or the SQLERRP field of the SQLCA) is set to the name of the module at the application requester that detected the error. Note that the first three characters of the module name identify the product. For example, if the application requester is Db2 LUW the first three characters are 'SQL'.

If the CONNECT statement is unsuccessful because the activation group is not in the connectable state, the connection state of the activation group is unchanged.

If the CONNECT statement is unsuccessful for any other reason:

- The activation group remains in a connectable, but unconnected state
- All open cursors are closed, all prepared statements are destroyed, and all locks are released from all current and dormant connections.

An application in a connectable but unconnected state can only execute the CONNECT or SET CONNECTION statements.

Implicit connect:

- When running in the default activation group, the SQL program implicitly connects to a remote relational database when:
 - The activation group is in a connectable state.
 - The first SQL statement in the first SQL program on the program stack is executed.
- When running in a non-default activation group, the SQL program implicitly connects to a remote relational database when the first SQL statement in the first SQL program for that activation group is executed.

Note: It is a good practice for the first SQL statement executed by an activation group to be the CONNECT statement.

When APPC is used for connecting to an RDB, implicit connect always sends the *authorization-name* of the application requester job and does not send passwords. If the *authorization-name* of the application server job is different, or if a password must be sent, an explicit connect statement must be used.

When TCP/IP is used for connecting to an RDB, an implicit connect is not bound by the above restrictions. Use of the ADDSVRAUTE and other -SVRAUTE commands allows one to specify, for a given user under which the implicit (or explicit) CONNECT is done, the remote authorization-name and password to be used in connecting to a given RDB.

In order for the password to be stored with the ADDSVRAUTE or CHGSVRAUTE command, the QRETSVRSEC system value must be set to '1' rather than the default of '0'. When using these commands for DRDA connection, it is very important to realize that the value of the RDB name entered into the SERVER parameter must be in UPPER CASE. For more information, see Example 2 under Type 2 CONNECT.

For more information about implicit connect, refer to the [SQL Programming topic collection](#). Once a connection to a relational database for a user profile is established, the password, if specified, may not be validated again on subsequent connections to the same relational database with the same user profile.

⁸⁹ To reduce the possibility of confusion between network connections and SQL connections, in this book the term 'conversation' will be used to apply to network connections over TCP/IP as well as over APPC, even though it formally applies only to APPC connections.

Revalidation of the password depends on if the conversation is still active. See the [Distributed Database Programming](#) topic collection for more details.

Connection states: For a description of connection states, see “[Remote unit of work connection management](#)” on page 37. Consecutive CONNECT statements can be executed successfully because CONNECT does not remove the activation group from the connectable state.

A CONNECT to either a current or dormant connection in the application group is executed as follows:

- If the connection identified by the server-name was established using a CONNECT (type 1) statement, then no action is taken. Cursors are not closed, prepared statements are not destroyed, and locks are not released.
- If the connection identified by the server-name was established using a CONNECT (type 2) statement, then the CONNECT statement is executed like any other CONNECT statement.

CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, DISCONNECT, SET CONNECTION, RELEASE, or ROLLBACK. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

If any previous current or dormant connections were established using protected conversations, then the CONNECT (type 1) statement will fail. Either, a CONNECT (type 2) statement must be used, or the connections using protected conversations must be ended by releasing the connections and successfully committing.

For more information about connecting to a remote relational database and the local directory, see [SQL Programming](#) and the [Distributed Database Programming](#).

SET SESSION AUTHORIZATION: If a SET SESSION AUTHORIZATION statement has been executed in the thread, a CONNECT to the local server will fail unless prior to the connect statement, the SYSTEM_USER value is the same as SESSION_USER.

This includes an implicit connect due to invoking a program that specifies ACTGRP(*NEW).

Examples

Example 1: In a C program, connect to the application server TOROLAB.

```
EXEC SQL CONNECT TO TOROLAB;
```

Example 2: In a C program, connect to an application server whose name is stored in the variable APP_SERVER (VARCHAR(18)). Following a successful connection, copy the product identifier of the application server to the variable PRODUCT.

```
void main ()  
{  
    char product[9] = " ";  
    EXEC SQL BEGIN DECLARE SECTION;  
    char APP_SERVER[19];  
    char username[11];  
    char userpass[129];  
    EXEC SQL END DECLARE SECTION;  
    EXEC SQL INCLUDE SQLCA;  
    strcpy(APP_SERVER,"TOROLAB");  
    strcpy(username,"JOE");  
    strcpy(userpass,"XYZ1");  
    EXEC SQL CONNECT TO :APP_SERVER  
        USER :username USING :userpass;  
    if (strcmp(SQLSTATE, "00000", 5) )  
    { EXEC SQL GET DIAGNOSTICS CONDITION 1  
        product = DB2_PRODUCT_ID; }  
    ...  
    return;  
}
```

CONNECT (type 2)

The CONNECT (type 2) statement connects an activation group within an application process to the identified application server using the rules for application directed distributed unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*DUW) was specified on the CRTSQLxxx command.

Differences between the two types of statements are described in “[CONNECT \(type 1\) and CONNECT \(type 2\) differences](#)” on page 1429. Refer to “[Application-directed distributed unit of work](#)” on page 38 for more information about connection states.

Invocation

This statement can only be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in the [Distributed Database Programming topic collection](#).)

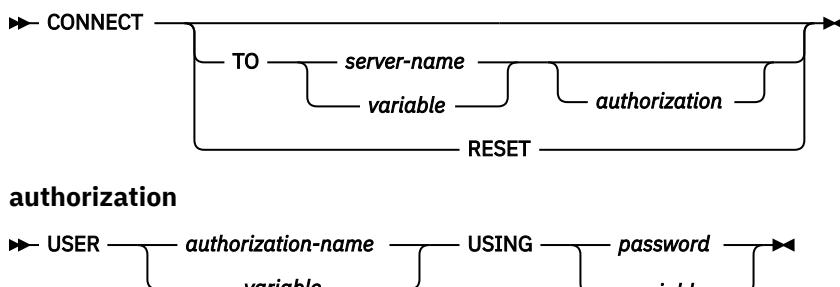

If the application server is Db2 for i, the profile ID of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

- USER is specified. If USER is specified, the USER clause must specify a valid user profile on the application server system.
- TCP/IP is used with a server authorization entry for the application server. If this is the case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

TO *server-name* or *variable*

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.

- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory.

Let S denote the specified server name or the server name contained in the variable. S must not identify an existing connection of the application process.

USER *authorization-name or variable*

Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a *variable* is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable. The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.
- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.

USING *password or variable*

Identifies the password that will be used to connect to the application server.

If password is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a *variable* is specified:

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.

RESET

CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.

CONNECT with no operand

This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).

In addition, the DB2_CONNECTION_STATUS connection information item in the SQL Diagnostics Area (or the SQLERRD(3) field of the SQLCA) will indicate the status of connection for this unit of work. It will have one of the following values:

- 1 - Committable updates can be performed on the connection for this unit of work.
- 2 - No committable updates can be performed on the connection for this unit of work.

Notes

Successful connection: If the CONNECT statement is successful:

- A connection to application server S is created and placed in the current and held states. The previous connection, if any, is placed in the dormant state.
- S is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the *connection-information-items* in the SQL Diagnostics Area.
- Information about application server S is also placed in the SQLERRP and SQLERRD(4) fields of the SQLCA. If the application server is an IBM relational database product, the information in the SQLERRP field has the form *pppvrrm*, where:
 - *ppp* identifies the product as follows:
 - ARI for Db2 for VM and VSE
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for all other Db2 products
 - *vv* is a two-digit version identifier such as '09'
 - *rr* is a two-digit release identifier such as '01'
 - *m* is a one-character modification level such as '0'

For example, if the application server is Version 9 of Db2 for z/OS, the value of SQLERRP is 'DSN09010'.

The SQLERRD(4) field of the SQLCA contains values indicating whether application server S allows committable updates to be performed. Following is a list of values and their meanings for the SQLERRD(4) field of the SQLCA on the CONNECT:

- 1 - committable updates can be performed. Conversation is unprotected.⁸⁹
- 2 - No committable updates can be performed. Conversation is unprotected.
- 3 - It is unknown if committable updates can be performed. Conversation is protected.
- 4 - It is unknown if committable updates can be performed. Conversation is unprotected.
- 5 - It is unknown if committable updates can be performed. The connection is either a local connection or a connection to an application requester driver program.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to Appendix C, “SQLCA (SQL communication area),” on page 1431.

Unsuccessful connection: If the CONNECT statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Implicit connect: Implicit connect will always send the *authorization-name* of the application requester job and will not send passwords. If the *authorization-name* of the application server job is different or if a password must be sent, an explicit connect statement must be used.

When TCP/IP is used for connecting to an RDB, an implicit connect is not bound by the above restrictions. Use of the ADDSVRAUTE and other -SVRAUTE commands allows one to specify, for a given user under which the implicit (or explicit) CONNECT is done, the remote authorization-name and password to be used in connecting to a given RDB.

In order for the password to be stored with the ADDSVRAUTE or CHGSVRAUTE command, the QRETSVRSEC system value must be set to '1' rather than the default of '0'. When using these commands for DRDA connection, it is very important to realize that the value of the RDB name entered into the SERVER parameter must be in UPPER CASE. For more information, see Example 2 under Type 2 CONNECT.

For more information about implicit connect, refer to [SQL Programming](#). Once a connection to a relational database for a user profile is established, the password, if specified, may not be validated again on subsequent connections to the same relational database with the same user profile. Revalidation of the password depends on if the conversation is still active. See [Distributed Database Programming](#) for more details.

SET SESSION AUTHORIZATION: If a SET SESSION AUTHORIZATION statement has been executed in the thread, a CONNECT to the local server will fail unless prior to the connect statement, the SYSTEM_USER value is the same as SESSION_USER.

This includes an implicit connect due to invoking a program that specifies ACTGRP(*NEW).

Examples

Example 1: Execute SQL statements at TOROLAB and SVLLAB. The first CONNECT statement creates the TOROLAB connection and the second CONNECT statement places it in the dormant state.

```
EXEC SQL CONNECT TO TOROLAB;
  (execute statements referencing objects at TOROLAB)
EXEC SQL CONNECT TO SVLLAB;
  (execute statements referencing objects at SVLLAB)
```

Example 2: Connect to a remote server specifying a userid and password, perform work for the user and then connect as another user to perform further work.

```
EXEC SQL CONNECT TO SVLLAB USER :AUTHID USING :PASSWORD;
  (execute SQL statements accessing data on the server)
EXEC SQL COMMIT;
  (set AUTHID and PASSWORD to new values)
EXEC SQL CONNECT TO SVLLAB USER :AUTHID USING :PASSWORD;
  (execute SQL statements accessing data on the server)
```

Example 3: User JOE wants to connect to TOROLAB3 and execute SQL statements under the user ID ANONYMOUS which has a password of SHIBBOLETH. The RDB directory entry for TOROLAB3 specifies *IP for the connection type.

Before running the application, some setup must be done.

This command will be required to allow server security information to be retained in the IBM i operating system, if it has not been previously run:

```
CHGSYSVAL SYSVAL(QRETSVRSEC) VALUE('1')
```

This command adds the required server authorization entry:

```
ADDSVRAUTE USRPRF(JOE) SERVER(TOROLAB3) USRID(ANONYMOUS) +
  PASSWORD(SHIBBOLETH)
```

This statement, run under JOE's user profile, will now make the wanted connection:

```
EXEC SQL CONNECT TO TOROLAB3;
  (execute statements referencing objects at TOROLAB3)
```

CREATE ALIAS

The CREATE ALIAS statement defines an alias on a table, partition of a table, view, or member of a database file at the current or remote server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Create DDM File (CRTDDMF) command
- Database administrator authority

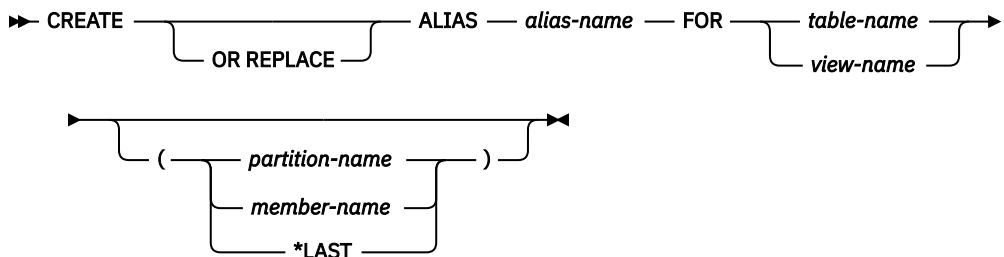

If SQL names are specified and a user profile exists that has the same name as the library into which the alias is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

To replace an existing alias, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the alias
 - All authorities needed to DROP the alias
- Database administrator authority

Syntax

Description

OR REPLACE

Specifies to replace the definition for the alias if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the alias are not affected. This option is ignored if a definition for the alias does not exist at the current server.

alias-name

Names the alias. The name, including the implicit or explicit qualifier, must not be the same as an index, table, view, alias or file that already exists at the current server.

If the *alias-name* is qualified, the name can be a two-part or three-part name. The schema name should not be a system schema. If a three-part name is used, the first part must identify a relational database name in the relational database directory.

For more information about connecting to a remote relational database and the local directory, see [SQL Programming](#) and the [Distributed Database Programming](#).

If SQL names were specified, the alias will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the alias will be created in the schema that is specified by the qualifier. If not qualified, the alias will be created in the same schema as the table or view for which the alias was created. If the table is not qualified and does not exist at the time the alias is created:

- If the value of the CURRENT SCHEMA special register is *LIBL, the alias will be created in the current library (*CURLIB).
- Otherwise, the alias will be created in the current schema.

If the alias name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see [“Rules for Table Name Generation” on page 994](#).

FOR *table-name* or *view-name*

Identifies the table or view at the current or remote server for which the alias is to be defined. An alias name cannot be specified (an alias cannot refer to another alias), unless the name refers to an alias on a remote server.

The *table-name* or *view-name* need not identify a table or view that exists at the time the alias is created. If the table or view does not exist when the alias is created, a warning is returned. If the table or view does not exist when the alias is used, an error is returned.

If SQL names were specified and the *table-name* or *view-name* was not qualified, then the qualifier is the implicit qualifier. For more information, see [“Naming conventions” on page 47](#).

If system names were specified and the *table-name* or *view-name* is not qualified and does not exist when the alias is created, the *table-name* or *view-name* is qualified by the library in which the alias is created.

partition-name

Identifies a partition of a partitioned table.

If a partition is specified, the alias cannot be used in SQL schema statements. If a partition is not specified, all partitions in the table are included in the alias.

If a partition name is specified, a three-part name should not be specified in the FOR clause. If a three-part name is specified and identifies a different relational database than the relational database of the alias, any attempt to use the alias will fail.

***member-name* or *LAST**

Identifies a member of a database file. If a member name is not specified and the table is not a partitioned table, *FIRST is used. If a member name is not specified and the table is a partitioned table, all members (partitions) are used.

If *LAST is specified, the last member of the database file is used. This is the member that was most recently created.

If a member or *LAST is specified, the alias cannot be used in most SQL schema statements. It can be used in CREATE PROCEDURE, CREATE FUNCTION and in a CREATE TABLE with an *as-result-table* clause.

If a member name is specified, a three-part name should not be specified in the FOR clause. If a three-part name is specified and identifies a different relational database than the relational database of the alias, any attempt to use the alias will fail.

Notes

Alias references: An alias can be defined to reference either the system name or SQL name. Since system names are generated during create processing, it is generally recommended that the SQL name be specified.

However, if the alias specifies a reference to a three-part name and the alias will be used as a DDM file in native commands or native access, the name specified must be the system name.

The Override Database File (OVRDBF) CL command also allows the database manager to process individual members of a database file. Creating an alias over a partition of a table or member of a database file, however, is easier and performs better by eliminating the need to perform the override.

Alias attributes: An alias is created as a special form of a DDM file. Both an alias and a normal DDM file can be used in SQL, but if the alias or DDM file specifies a non-local relational database name, the specified *table-name* or *view-name* must be the same as the name of the alias.

An alias created over a distributed table is only created on the current server. For more information about distributed tables, see [DB2 Multisystem](#).

Alias ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the alias is created exists, the *owner* of the alias is that user profile.
- Otherwise, the *owner* of the alias is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the alias is the user profile or group user profile of the thread executing the statement.

Alias authority: If SQL names are used, aliases are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, aliases are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the alias is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the alias.

REPLACE rules: When an alias is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

Packages and three-part aliases: When an application uses three-part name aliases for remote objects and DRDA access, a package for the application program must exist at each location that is specified in the three-part names. A package can be explicitly created using the CRTSQLPKG CL command. If the three-part name alias is referenced and a package does not exist, the database manager will attempt to implicitly create the package.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword SYNONYM can be used as a synonym for ALIAS.

Examples

Example 1: Create an alias named CURRENT_PROJECTS for the PROJECT table.

```
CREATE ALIAS CURRENT_PROJECTS  
FOR PROJECT
```

Example 2: Create an alias named SALES_JANUARY on the JANUARY partition of the SALES table. The sales table has 12 partitions (one for each month of the year).

```
CREATE ALIAS SALES_JANUARY  
FOR SALES(JANUARY)
```

Example 3: Create an alias named REPORTS.SALES for the SALES table in schema REPORTS on relational database USARDB.

```
CREATE ALIAS REPORTS.SALES  
FOR USARDB.REPORTS.SALES
```

CREATE FUNCTION

The CREATE FUNCTION statement defines a user-defined function at the current server.

The following types of functions can be defined:

- **External Scalar**

The function is written in a programming language such as C or Java and returns a scalar value. The external program is referenced by a function defined at the current server along with various attributes of the function. See “[CREATE FUNCTION \(external scalar\)](#)” on page 817.

- **External Table**

The function is written in a programming language such as C or Java and returns a set of rows. The external program is referenced by a function defined at the current server along with various attributes of the function. See “[CREATE FUNCTION \(external table\)](#)” on page 836.

- **Sourced**

The function is implemented by invoking another function (built-in, external, sourced, or SQL) that already exists at the current server. A sourced function can return a scalar result, or the result of an aggregate function. See “[CREATE FUNCTION \(sourced\)](#)” on page 854. The function inherits attributes of the underlying source function.

- **SQL Scalar**

The function is written exclusively in SQL and returns a scalar value. The body of an SQL function is written in the SQL procedural language, SQL PL. The function body is defined at the current server along with various attributes of the function. See “[CREATE FUNCTION \(SQL scalar\)](#)” on page 863.

- **SQL Table**

The function is written exclusively in SQL and returns a set of rows. The body of an SQL function is written in the SQL procedural language, SQL PL. The function body is defined at the current server along with various attributes of the function. See “[CREATE FUNCTION \(SQL table\)](#)” on page 877.

Notes

Choosing the schema and function name: If a qualified function name is specified, the *schema-name* cannot be one of the system schemas (see “[Schemas](#)” on page 4). If *function-name* is not qualified, it is implicitly qualified with the default schema name.

The unqualified function name must not be one of the following names reserved for system use even if they are specified as delimited identifiers:

=	<	>	>=
<=	<>	=	<
=<	!=	<	>
ALL	FALSE	POSITION	XMLEGG
AND	FOR	RID	XMLATTRIBUTES
ANY	FROM	RRN	XMLCOMMENT
ARRAY_AGG	HASHED_VALUE	SELECT	XMLENCAT
BETWEEN	IN	SIMILAR	XMLEDOCUMENT
BOOLEAN	IS	SOME	XMLELEMENT
CASE	LIKE	STRIP	XMLEFOREST
CAST	MATCH	SUBSTRING	XMLEGROUP

CHECK	NODENAME	TABLE	XMLNAMESPACES
DATAPARTITIONNAME	NODENUMBER	THEN	XMLPARSE
DATAPARTITIONNUM	NOT	TRIM	XMLPI
DBPARTITIONNAME	NULL	TRUE	XMLROW
DBPARTITIONNUM	ONLY	TYPE	XMLSERIALIZE
DISTINCT	OR	UNIQUE	XMLTEXT
EXCEPT	OVERLAPS	UNKNOWN	XMLVALIDATE
EXISTS	PARTITION	WHEN	XSLTRANSFORM
EXTRACT			

Defining the parameters: The input parameters for the function are specified as a list within parenthesis.

The maximum number of parameters allowed in CREATE FUNCTION is 2000.

A function can have no input parameters. In this case, an empty set of parenthesis must be specified, for example:

```
CREATE FUNCTION WOOFER()
```

The data type of the result of the function is specified in the RETURNS clause for the function.

- **Choosing data types for parameters:** When choosing the data types of the input and result parameters for a function, the rules of promotion that can affect the values of the parameters need to be considered. See “Promotion of data types” on page 79. For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC

For portability of functions across platforms that are not Db2 for i, do not use the following data type names, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

- **Specifying AS LOCATOR for a parameter:** Passing a locator instead of a value can result in fewer bytes being passed in or out of the function. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters that have a LOB or XML data type or a distinct type based on a LOB or XML data type and only when LANGUAGE JAVA is not in effect.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

AS LOCATOR cannot be specified for SQL functions.

Determining the uniqueness of functions in a schema: The same name can be used for more than one function in a schema if the function signature of each function is unique. The function signature is the qualified function name combined with the number and data types of the input parameters. The combination of name, schema name, the number of parameters, and the data type each parameter (without regard for other attributes such as length, precision, scale, or CCSID) must not identify a user-defined function that exists at the current server. The return type has no impact on the determining

uniqueness of a function. Two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a schema must not contain two functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, the database manager does not consider any length, precision, or scale attributes in the comparison. The database manager considers the synonyms of data types a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), and DECIMAL(4,3). Furthermore, the character and graphic types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type. A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...

CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

Specifying a specific name for a function: When defining multiple functions with the same name and schema (with different parameter lists), it is recommended that a specific name also be specified. The specific name can be used to uniquely identify the function such as when sourcing on this function, dropping the function, or commenting on the function. However, the function cannot be invoked by its specific name.

The specific name is implicitly or explicitly qualified with a schema name. If a schema name is not specified on CREATE FUNCTION, it is the same as the explicit or implicit schema name of the function name (*function-name*). If a schema name is specified, it must be the same as the explicit or implicit schema name of the function name. The name, including the schema name must not identify the specific name of another function or procedure that exists at the current server.

If a specific name is not specified, it is set to the function name. If a function or procedure with that specific name already exists, a unique name is generated similar to the rules used to generate unique table names.

Extending or overriding a built-in function:

Giving a user-defined function the same name as a built-in function is not a recommended practice unless the functionality of the built-in function needs to be extended or overridden.

- **Extending the functionality of existing built-in functions:**

Create the new user-defined function with the same name as the built-in function, and a unique function signature. For example, a user-defined function similar to the built-in function ROUND that accepts the strongly typed distinct type MONEY as input rather than the built-in numeric types might be necessary. In this case, the signature for the new user-defined function named ROUND is different from all the function signatures supported by the built-in ROUND function.

- **Overriding a built-in function:**

Create the new user-defined function with the same name and signature as an existing built-in function. The new function has the same name and data type as the corresponding parameters of the built-in function but implements different logic. For example, a user-defined function similar to the built-in function ROUND that uses different rules for rounding than the built-in ROUND function might be necessary. In this case, the signature for the new user-defined function named ROUND will be the same as a signature that is supported by the built-in ROUND function.

Once a built-in function has been overridden, if the schema for the new function appears in the SQL path before the system schemas, the database manager may choose a user-defined function rather than the built-in function. An application that uses the unqualified function name and was previously successful using the built-in function of that name might fail, or perhaps even worse, appear to run successfully but provide a different result if the user-defined function is chosen by the database manager rather than the built-in function.

The DISTINCT keyword can be passed on the invocation of a user-defined function that is sourced on one of the built-in aggregate functions. For example, assume that MY_AVG is a user-defined function that is sourced on the built-in AVG function. The user-defined function could be invoked with MY_AVG (DISTINCT *expression*). This results in the underlying built-in AVG function being invoked with the DISTINCT keyword.

Special registers in functions: The settings of the special registers of the invoker are inherited by the function on invocation and restored upon return to the invoker. Special registers may be changed in a function that can execute SQL statements, but these changes do not affect the caller.

Creating a secure function: Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assumes that such an audit control procedure is in place for all subsequent ALTER FUNCTION statements.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized who has security administrator authority needs to ensure that those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

MODIFIES SQL DATA and EXTERNAL ACTION functions: If a MODIFIES SQL DATA or EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

Functions and adopted authority: Fenced functions run in separate threads. If ALLOW PARALLEL is specified for a NOT FENCED function, that function may also run in a separate thread. Functions that run in separate threads will not run under any adopted authority that might be specified by the invoking application.

Restore considerations: When a function's associated program or service program is saved and subsequently restored and the object was updated with the function attributes when the function was created, the saved attributes will be processed and possibly changed during the restore.

If the 'Saved library' (SAVLIB) of the program or service program is different from the 'Restore to library' (RSTLIB), the function's schema name, specific schema name, and the external name may be changed as a result of the restore.

- If the saved function schema name and the library name of the saved object match, the function schema will be changed to the 'Restore to library' (RSTLIB). Otherwise, the function schema name is the saved function schema name.
- The specific schema name is always the same as function schema name.
- If the saved EXTERNAL NAME library and the library name of the saved object match, the EXTERNAL NAME library will be changed to the 'Restore to library' (RSTLIB). Otherwise, the EXTERNAL NAME library is the saved library name. If the saved EXTERNAL NAME library is *LIBL, it will not change.

If the same function signature already exists in the catalog:

- If the external program name or service program name is the same as the one that already exists in the catalog, the information in the catalog for that procedure will be replaced with the saved attributes (including the specific name).
- Otherwise, the saved attributes are not restored, and a warning (SQL9015) is issued.

If the same specific name already exists in the catalog, a warning is issued and a new specific name is generated. Otherwise, the specific name of the function is preserved.

CREATE FUNCTION (external scalar)

This CREATE FUNCTION (external scalar) statement defines an external scalar function at the current server. A user-defined external scalar function returns a single value each time it is invoked.

Invocation

This statement can be embedded in an application program, or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table⁹⁰:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
 - The USAGE privilege on the schema that contains the external program or service program.
 - The system authority *EXECUTE on the external program or service program.
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

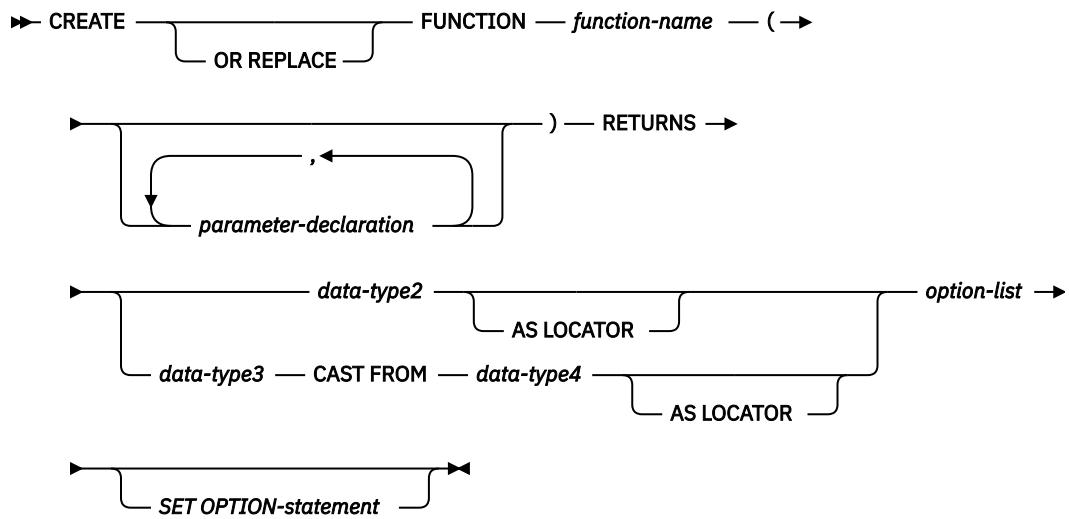

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authority *EXECUTE on the external program or service program
 - All authorities needed to DROP the function
 - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

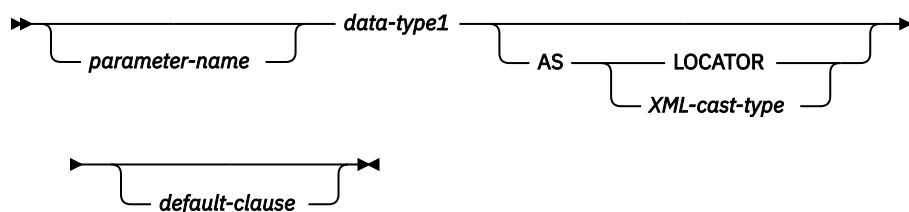

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

⁹⁰ The GROUTOBJAUT CL command must be used to grant these privileges.

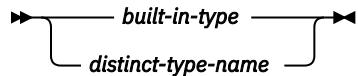

Syntax

Notes:

¹ This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the *specific-name* and *function-name* of the new definition must be the same as the *specific-name* and *function-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server unless OR REPLACE is specified.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in “[CREATE FUNCTION](#)” on page 813.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function.

The maximum number of parameters depends on the type of language:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs, the maximum is 90.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in “[CREATE FUNCTION](#)” on page 813.

parameter-name

Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type. It cannot be an array type.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see “[CREATE TABLE](#)” on page 945. Some data types are not supported in all languages.

For details on the mapping between the SQL data types and host language data types,

see [Embedded SQL Programming](#) topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the user-defined function.

distinct-type-name

Specifies a user-defined distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information on creating a distinct type, see “[CREATE TYPE \(distinct\)](#)” on page 1017.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Any parameter that has an XML type must specify either the *XML-cast-type* clause or the AS LOCATOR clause.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “[CREATE FUNCTION](#)” on page 813.

AS *XML-cast-type*

Specifies the data type passed to the function for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the function is created according to the SQL_XML_DATA_CCSID_QAQQINI option setting. The default CCSID is 1208. See “[XML Values](#)” on page 75 for a description of this option.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created. When the function is invoked, the default will be evaluated using the authority of the invoker.

A default cannot be specified for a parameter of type array.

RETURNS

Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

data-type2

Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or DataLink) or a distinct type (that is not based on a DataLink). You cannot specify an array type.

If a CCSID is specified,

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in that CCSID.
- If AS LOCATOR is specified and the CCSID of the data the locator points to is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified and the function is not referenced in the outermost select list of a view,

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the job (or associated graphic CCSID of the job for graphic string return values).
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the job, if the CCSID of the data the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

If a CCSID is not specified and the function is referenced in the outermost select list of a view,

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the associated view column.
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the associated view column, if the CCSID of the data the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. Specify AS LOCATOR only if the result of the function has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in [“CREATE FUNCTION” on page 813](#).

data-type3 CAST FROM data-type4

Specifies the data type and attributes of the function (*data-type4*) and the data type in which that result is returned to the invoking statement (*data-type3*). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which the database manager converts to a DECIMAL value and then passes to the statement that invoked the function:

```
CREATE FUNCTION SQRT (DECIMAL15,0))
RETURNS DECIMAL(15,0)
CAST FROM DOUBLE
...
```

The value of *data-type4* must not be XML or a distinct type and must be castable to *data-type3*. The value for *data-type3* can be any built-in data type or distinct type. (For information on casting data types, see [“Casting between data types” on page 81](#)).

For CCSID information, see the preceding description of *data-type2*.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. Specify AS LOCATOR only if the result of the function has a LOB data type or a distinct type based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in [“CREATE FUNCTION” on page 813](#).

LANGUAGE

Specifies the language interface convention to which the function body is written. All programs must be designed to run in the server's environment.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program at the time the function is created. The language of the program is assumed to be C if:

- The program attribute information associated with the program does not identify a recognizable language
- The program cannot be found

C

The external program is written in C.

C++

The external program is written in C++.

CL

The external program is written in CL or ILE CL.

COBOL

The external program is written in COBOL.

COBOLLE

The external program is written in ILE COBOL.

JAVA

The external program is written in JAVA. The database manager will call the user-defined function, which must be a public static method of the specified Java class

Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, or DBINFO is specified.

PLI

The external program is written in PL/I.

RPG

The external program is written in RPG.

RPGLE

The external program is written in ILE RPG.

PARAMETER STYLE

Specifies the conventions used for passing parameters to and returning the values from functions:

SQL

All applicable parameters are passed. The parameters are defined to be in the following order:

- n parameters for the input parameters that are specified for the function.
- A parameter for the result of the function.
- n parameters for indicator variables for the input parameters.
- A parameter for the indicator variable for the result.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the function. The SQLSTATE returned can either be:
 - the SQLSTATE from the last SQL statement executed in the external program,
 - an SQLSTATE that is assigned by the external program.

The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.

- A VARCHAR(517) input parameter for the fully qualified function name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.

When control is returned to the invoking program, the message text can be found in the 6th token of the SQLERRMC field of the SQLCA. Only a portion of the message text is available. For information on the layout of the message data in the SQLERRMC, see the replacement data descriptions for message SQL0443 in message file QSQLMSG. The complete message text can be retrieved using the GET DIAGNOSTICS statement. For more information, see “[GET DIAGNOSTICS](#)” on page 1144.

- Zero to three optional parameters:
 - A structure (consisting of an INTEGER followed by a CHAR(n)) input and output parameter for the scratchpad, if SCRATCHPAD was specified on the CREATE FUNCTION statement.
 - An INTEGER input parameter for the call type, if FINAL CALL was specified on the CREATE FUNCTION statement.
 - A structure for the dbinfo structure, if DBINFO was specified on the CREATE FUNCTION statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DB2GENERAL

This parameter style is used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- A parameter for the result of the function.

DB2GENERAL is only allowed when the LANGUAGE is JAVA.

GENERAL

All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.

Note that the result is returned as a value of a C value returning function. For example:

```
return_val func(parameter-1, parameter-2, ...)
```

GENERAL is only allowed when EXTERNAL NAME identifies a service program.

GENERAL WITH NULLS

All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- An additional argument is passed for an indicator variable array.
- A parameter for the indicator variable for the result.

Note that the result is returned as a value of a C value returning function. For example:

```
return_val func(parameter-1, parameter-2, ...)
```

GENERAL WITH NULLS is only allowed when EXTERNAL NAME identifies a service program.

JAVA

Specifies that the function will use a parameter passing convention that conforms to the Java language and ISO/IEC FCD 9075-13:2003, *Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)* specification. All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.

Note that the result is returned as a value of a C value returning function. For example:

```
return_val func(parameter-1, parameter-2, ...)
```

JAVA is only allowed when the LANGUAGE is JAVA.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the [SQL Programming](#) topic collection. For Java routines, see the [IBM Developer Kit for Java](#) topic collection.

SPECIFIC *specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “[CREATE FUNCTION](#)” on page 813.

GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a function that is not deterministic is one that generates random numbers.

A function that is not deterministic might return incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

NOT DETERMINISTIC should be specified if the function contains a reference to a special register, a non-deterministic function, or a sequence.

GLOBAL DETERMINISTIC

Specifies that the function always returns the same result each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic scalar function results.⁹¹ An example of a global deterministic function is a function that calculates the square root of the input argument.

STATEMENT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic scalar function results.⁹² An example of a statement deterministic function is a function that performs currency conversion.

CONTAINS SQL, READS SQL DATA, MODIFIES SQL DATA, or NO SQL

Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1421](#). The default is READS SQL DATA. This option is ignored for parameter default expressions.

⁹¹ If the result of the function contains sensitive data, consider using STATEMENT DETERMINISTIC or the DETERMINISTIC_UDF_SCOPE QAQQINI option or create the function NOT DETERMINISTIC to prevent inadvertent access to the result. For more information, see the [Database Performance and Query Optimization](#) topic collection.

⁹² The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the [Database Performance and Query Optimization](#) topic collection.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

NO SQL

Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

MODIFIES SQL DATA

The function can execute any SQL statement except those statements that are not supported in any function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time. CALLED ON NULL INPUT is the default.

RETURNS NULL ON INPUT

Specifies that the function is not invoked if any of the input arguments is null. The result is the null value.

CALLED ON NULL INPUT

Specifies that the function is to be invoked, if any, or all, argument values are null. This specification means that the function must be coded to test for null argument values. The function can return a null or nonnull value.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH

Specifies that the function is dispatched statically. All functions are statically dispatched.

NO DBINFO or DBINFO

Specifies whether additional status information is passed when the function is invoked. The default is NO DBINFO.

NO DBINFO

Specifies that no additional information is passed.

DBINFO

Specifies that the database manager should pass a structure containing status information to the function. [Table 92 on page 829](#) contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

Table 92. DBINFO fields

Field	Data Type	Description
Relational database	VARCHAR(128)	The name of the current server.
Authorization ID	VARCHAR(128)	The run-time authorization ID.

Table 92. DBINFO fields (continued)

Field	Data Type	Description
CCSID Information	INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER CHAR(8)	The CCSID information of the job. Three sets of three CCSIDs are returned. The following information identifies the three CCSIDs in each set: <ul style="list-style-type: none">• SBCS CCSID• DBCS CCSID• Mixed CCSID Following the three sets of CCSIDs is an integer that indicates which set of three sets of CCSIDs is applicable and eight bytes of reserved space. Each set of CCSIDs is for a different encoding scheme (EBCDIC, ASCII, and Unicode). If a CCSID is not explicitly specified for a parameter on the CREATE FUNCTION statement, the input string is assumed to be encoded in the CCSID of the job at the time the function is executed. If the CCSID of the input string is not the same as the CCSID of the parameter, the input string passed to the external function will be converted before calling the external program.
Target column	VARCHAR(128) VARCHAR(128) VARCHAR(128)	If a user-defined function is specified on the right-hand side of a SET clause in an UPDATE statement, the following information identifies the target column: <ul style="list-style-type: none">• Schema name• Base table name• Column name If the user-defined function is not on the right-hand side of a SET clause in an UPDATE statement, these fields are blank.
Version and release	CHAR(8)	The version, release, and modification level of the database manager.
Platform	INTEGER	The server's platform type.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

FENCED or NOT FENCED

Specifies whether the external function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB

This parameter is allowed for compatibility with other products. It indicates whether the routine's external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN

Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

PROGRAM TYPE SUB

Specifies that the routine executes as a procedure in a service program. The external program must be a *SRVPGM object.

NO FINAL CALL or FINAL CALL

Specifies whether a *final call* is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resources and stores them in the scratchpad. The default is NO FINAL CALL.

NO FINAL CALL

Specifies that a final call is not made to the function. The function does not receive an additional argument that specifies the type of call.

FINAL CALL

Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call.

FINAL CALL is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

The types of calls are:

First Call

Specifies the first call to the function for this reference to the function in this SQL statement. A first call is a normal call. SQL arguments are passed and the function is expected to return a result.

Normal Call

Specifies that SQL arguments are passed and the function is expected to return a result.

Final Call

Specifies the last call to the function to enable the function to free resources. A final call is not a normal call. If an error occurs, the database manager attempts to make the final call.

A final call occurs at these times:

- *End of statement:* When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.

- *End of a parallel task*: When the function is executed by parallel tasks.
- *End of transaction*: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

Committable operations should not be performed during a FINAL CALL, because the FINAL CALL may occur during a close that is invoked as part of a COMMIT operation.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, FINAL CALL, MODIFIES SQL DATA, or SCRATCHPAD. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, MODIFIES SQL DATA, SCRATCHPAD, and FINAL CALL for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL

Specifies that the database manager must not use parallelism for the function.

NO SCRATCHPAD or SCRATCHPAD

Specifies whether the function requires a static memory area.

NO SCRATCHPAD

Specifies that the function does not require a persistent memory area.

SCRATCHPAD *integer*

Specifies that the function requires a persistent memory area of length *integer*. The *integer* can range from 1 to 16,000,000. If the memory area is not specified, the size of the area is 100 bytes. If parameter style SQL is specified, a pointer is passed following the required parameters that points to a static storage area. If ALLOW PARALLEL is specified, a memory area is allocated for each user-defined function reference in the statement. If DISALLOW PARALLEL is specified, only 1 memory area will be allocated for the function.

The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A)
  FROM TABLEB
 WHERE UDFX(A) > 103 OR UDFX(A) < 19
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that will not work correctly with parallelism.

SCRATCHPAD is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

EXTERNAL

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

If *external-program-name* is not specified, the external program name is assumed to be the same as the function name.

NAME *external-program-name*

Specifies the program, service program, or Java class that will be executed when the function is invoked in an SQL statement. The name must identify a program, service program, or Java class that exists at the application server at the time the function is invoked. If the naming option is *SYS and the name is not qualified:

- The current path will be used to search for the program at the time the function is invoked.
- *LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the function.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The program, service program, or Java class need not exist at the time the function is created, but it must exist at the time the function is invoked.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statements are not allowed in the external program of the function.

NOT SECURED or SECURED

Specifies whether the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control. This option can be used for an external function that is written in C, C++, ILE RPG, ILE COBOL, ILE CL, or Java. The program or service program must exist when the CREATE FUNCTION statement is executed.

A function must be defined as secure when it is referenced in a row permission or a column mask.

SET OPTION-*statement*

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see “[SET OPTION](#)” on page 1303.

The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRL, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.

Notes

General considerations for defining user-defined functions: See “[CREATE FUNCTION](#)” on page 813 for general information on defining user-defined functions.

REPLACE rules: When an external function is recreated by REPLACE:

- Any existing comment or label is discarded.

- If a different external program is specified:
 - Authorized users are not copied to the new program.
 - Journal auditing is not changed.
- Otherwise:
 - Authorized users are maintained. The object owner will not change.
 - Current journal auditing is not changed.

Creating the function: When an external function associated with an ILE external program or service program is created, an attempt is made to save the function's attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external functions subject to the following restrictions:

- The external program library must not be QSYS.
- The external program must exist when the CREATE FUNCTION statement is issued.

If system naming is specified and the external program name is not qualified, the external program must be found in the library list.

- The external program must be an ILE *PGM or *SRVPGM object.

If the object cannot be updated, the function will still be created.

If the external function is created in QTEMP, the catalog information is not removed when the job ends.

Invoking the function: When an external function is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the function runs in the same activation group as the calling program. ACTGRP(*NEW) is not allowed.

LANGUAGE JAVA functions always run in the default activation group (*DFTACTGRP). Caution should be used when writing MODIFIES SQL DATA Java functions. Since changes performed by the Java function are performed in the default activation group, transaction problems may occur if the invoker runs in a new activation group (*NEW).

Notes for Java functions: To be able to run Java functions, you must have the IBM IBM Developer Kit for Java (5770-JV1) installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java function, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the function was run.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The keyword DB2GENRL may be used as a synonym for DB2GENERAL.
- The value DB2SQL may be used as a synonym for SQL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Examples

Example 1: Assume an external function program in C is needed that implements the following logic:

```
rslt = 2 * input - 4
```

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement. The following statement defines the function, using the specific name MINENULL1.

```
CREATE FUNCTION NTEST1 (SMALLINT)
RETURNS SMALLINT
EXTERNAL NAME NTESTMOD
SPECIFIC MINENULL1
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
RETURNS NULL ON NULL INPUT
NO EXTERNAL ACTION
```

The program code:

```
void nudft1
(int *input,           /* ptr to input argument      */
 int *output,          /* ptr to output argument     */
 short *input_ind,    /* ptr to input indicator    */
 short *output_ind,   /* ptr to output indicator   */
 char sqlstate[6],    /* sqlstate                   */
 char fname[140],     /* fully qualified function name */
 char finst[129],    /* function specific name     */
 char msgtext[71])   /* msg text buffer            */
{
    if (*input_ind == -1)
        *output_ind = -1;
    else
    {
        *output = 2*(*input)-4;
        *output_ind = 0;
    }
    return;
}
```

Example 2: Assume that a user wants to define an external function named CENTER. The function program will be written in C. The following statement defines the function, and lets the database manager generate a specific name for the function. The name of the program containing the function body is the same as the name of the function, so the EXTERNAL clause does not include 'NAME external-program-name'.

```
CREATE FUNCTION CENTER (INTEGER, FLOAT)
RETURNS FLOAT
LANGUAGE C
DETERMINISTIC
NO SQL
PARAMETER STYLE SQL
NO EXTERNAL ACTION
```

Example 3: Assume that user McBride (who has database administrator authority) wants to define an external function named CENTER in the SMITH schema. McBride plans to give the function specific name FOCUS98. The function program uses a scratchpad to perform some one-time only initialization and save the results. The function program returns a value with a DOUBLE data type. The following statement written by user McBride defines the function and ensures that when the function is invoked, it returns a value with a data type of DECIMAL(8,4).

```
CREATE FUNCTION SMITH.CENTER (DOUBLE, DOUBLE, DOUBLE)
RETURNS DECIMAL(8,4)
CAST FROM DOUBLE
EXTERNAL NAME CMOD
SPECIFIC FOCUS98
```

```
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
NO EXTERNAL ACTION
SCRATCHPAD
NO FINAL CALL
```

Example 4: The following example defines a Java user-defined function that returns the position of the first vowel in a string. The user-defined function is written in Java, is to be run fenced, and is the FINDVWL method of class JAVAUDFS.

```
CREATE FUNCTION FINDV (VARCHAR(32000))
RETURNS INTEGER
FENCED
LANGUAGE JAVA
PARAMETER STYLE JAVA
EXTERNAL NAME 'JAVAUDFS.FINDVWL'
NO EXTERNAL ACTION
CALLED ON NULL INPUT
DETERMINISTIC
NO SQL
```

CREATE FUNCTION (external table)

This CREATE FUNCTION (external table) statement defines an external table function at the current server. The function returns a result table.

An external user-defined *table function* may be used in the FROM clause of a subselect, and returns a table to the subselect by returning one row each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
 - The USAGE privilege on the schema that contains the external program or service program.
 - The system authority *EXECUTE on the external program or service program.
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

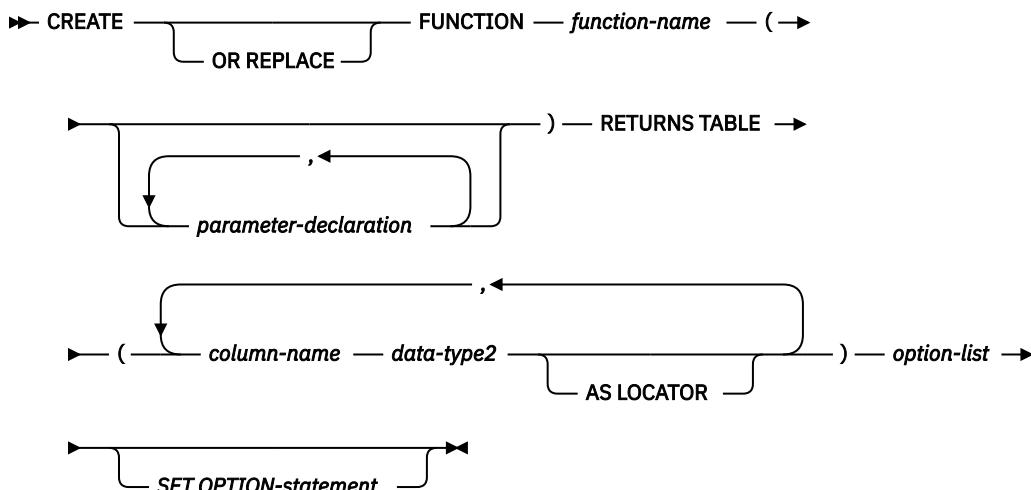

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

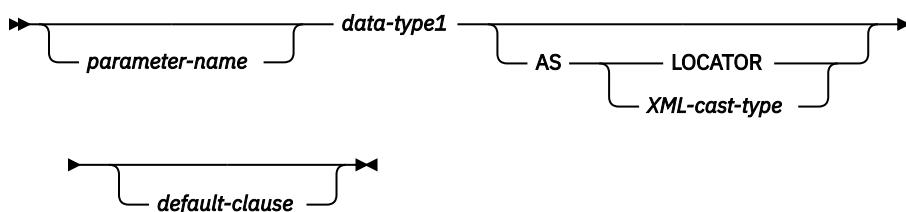

- The following system authorities:
 - The system authority *EXECUTE on the external program or service program
 - All authorities needed to DROP the function
 - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

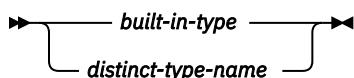

Syntax

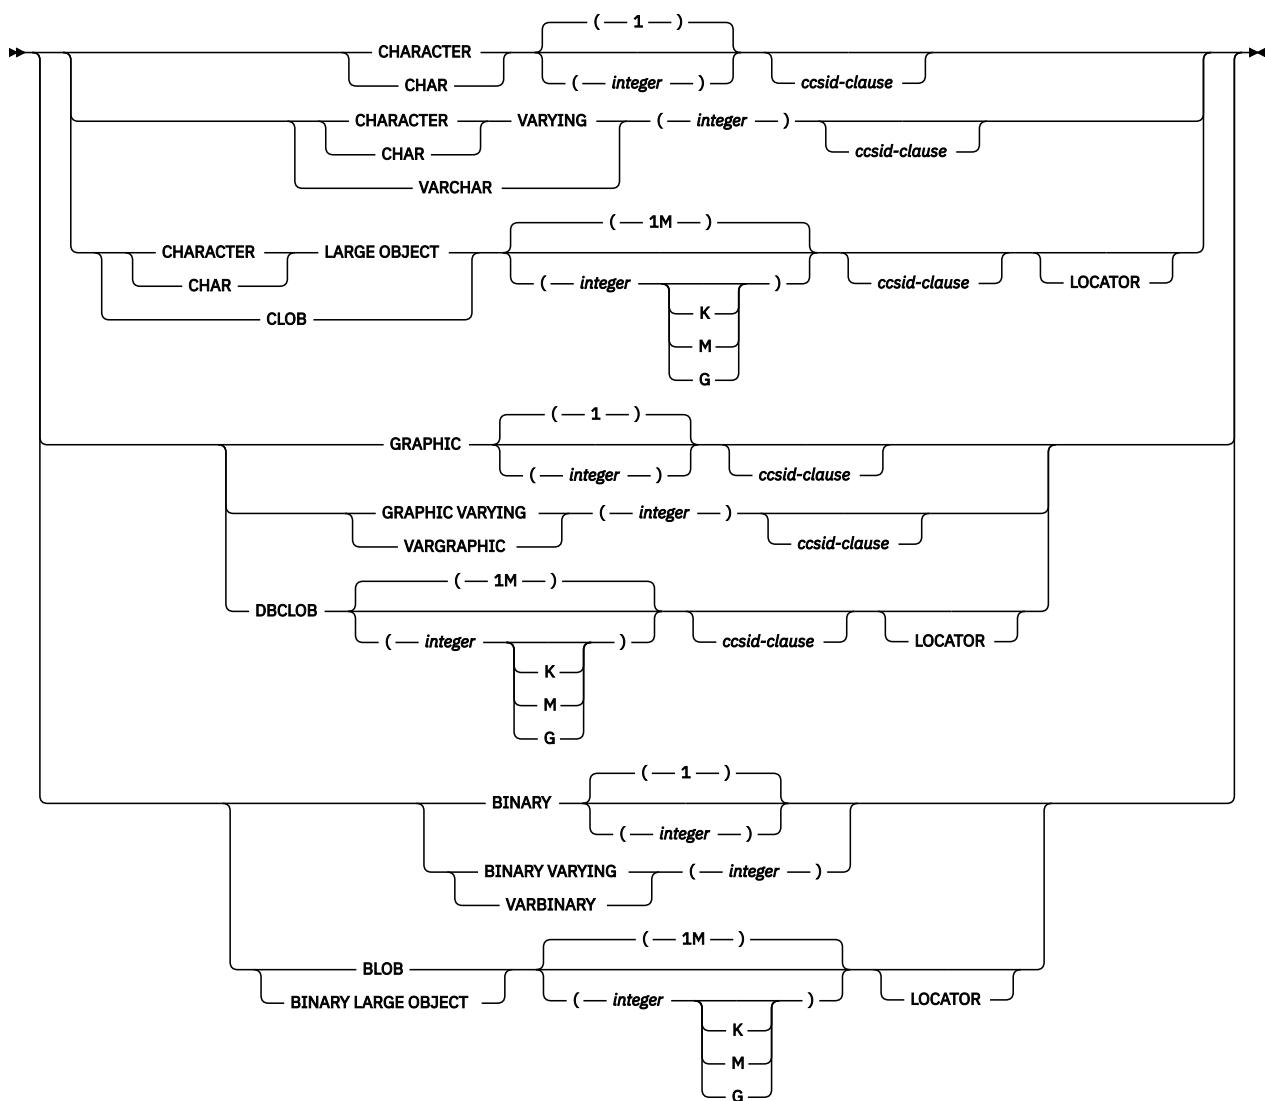

parameter-declaration

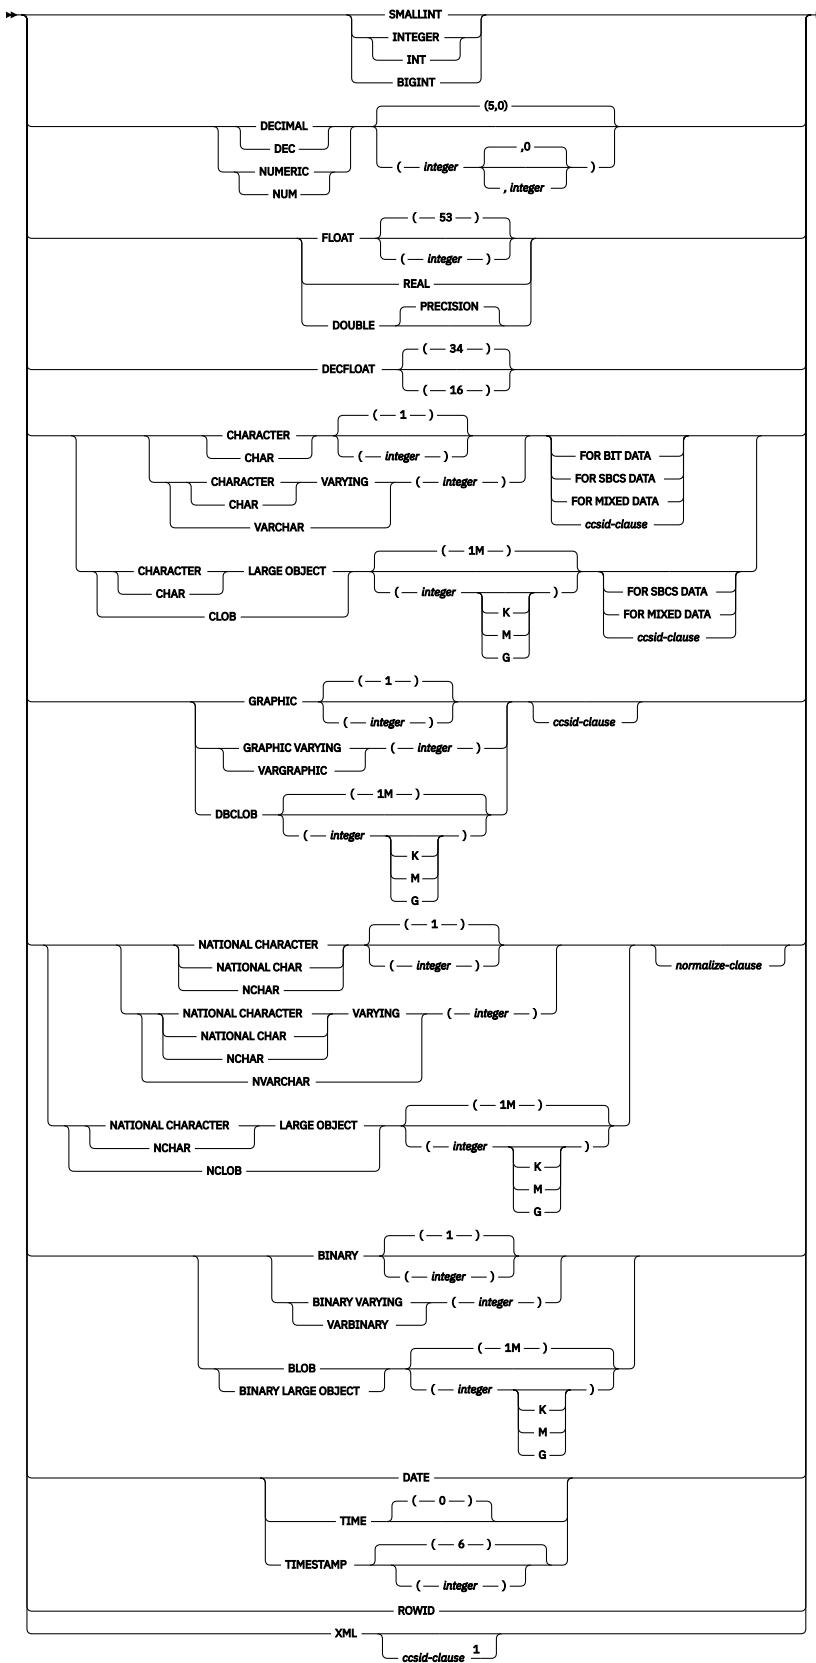

data-type1, data-type2

XML-cast-type

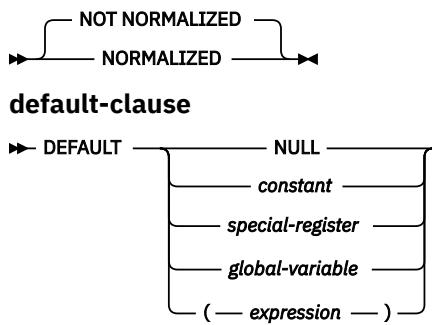

built-in-type

ccsid-clause

►► CCSID — *integer* ►►
normalize-clause

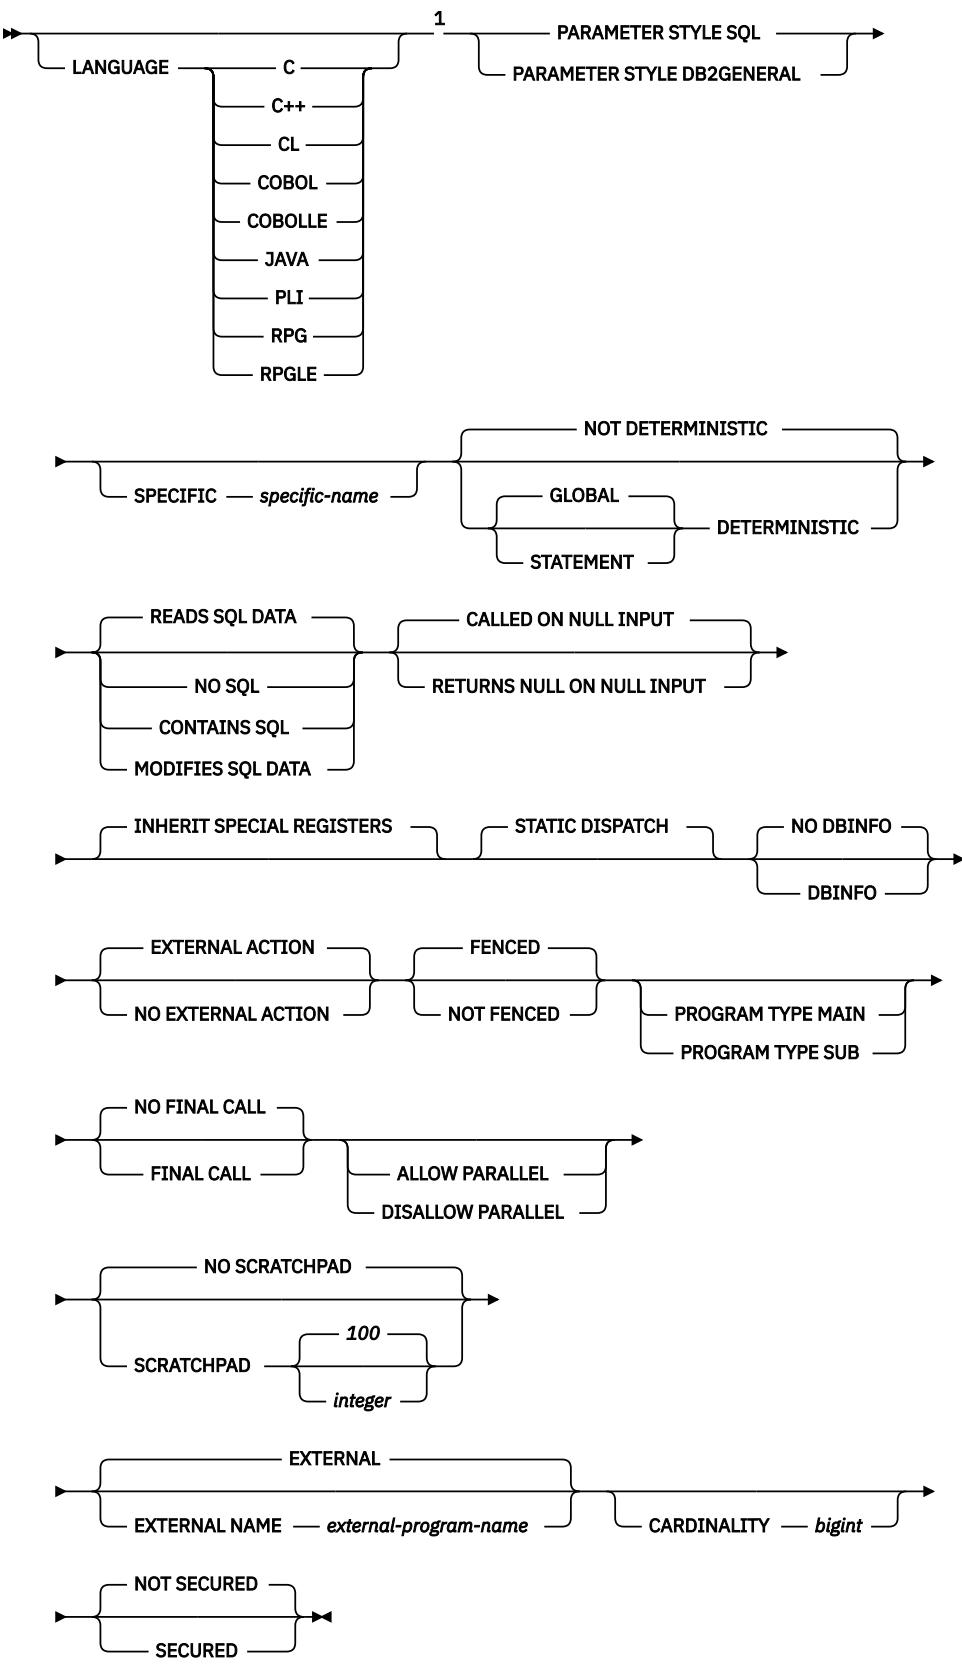

normalize-clause

Notes:

¹ The *ccsid-clause* for XML is only allowed for *data-type2*

option-list

Notes:

¹ This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the *specific-name* and *function-name* of the new definition must be the same as the *specific-name* and *function-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server unless OR REPLACE is specified.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the Schema and Function Name in “[CREATE FUNCTION](#)” on page 813.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function.

The maximum number of parameters depends on the type of language:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs, the maximum is 90.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in “[CREATE FUNCTION](#)” on page 813.

parameter-name

Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type. It cannot be an array type.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see “[CREATE TABLE](#)” on page 945. Some data types are not supported in all languages. For details on the mapping between the SQL data types and host language data types,

see [Embedded SQL Programming](#) topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the user-defined function.

distinct-type-name

Specifies a user-defined distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see “[CREATE TYPE \(distinct\)](#)” on page [1017](#)

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

Parameters with a large object (LOB) data type are not supported when PARAMETER STYLE JAVA is specified.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Any parameter that has an XML type must specify either the *XML-cast-type* clause or the AS LOCATOR clause.

AS LOCATOR

Specifies that the input parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the input parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “[CREATE FUNCTION](#)” on page [813](#).

AS *XML-cast-type*

Specifies the data type passed to the function for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the function is created according to the SQL_XML_DATA_CCSID_QAQQINI option setting. The default CCSID is 1208. See “[XML Values](#)” on page [75](#) for a description of this option.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page [147](#), that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created. When the function is invoked, the default will be evaluated using the authority of the invoker.

A default cannot be specified for a parameter of type array.

RETURNS TABLE

Specifies that the output of the function is a table. The parenthesis that follow this clause enclose a list of names and the data types of the columns of the result table.

The maximum number of result columns depends on the type of language. Assume that the number of parameters is N .

- For JAVA and ILE programs and service programs, there must be no more than $8000 - N$ columns.
- For OPM programs, there must be no more than $125 - N$ columns.

column-name

Specifies the name of a column of the output table. Do not specify the same name more than once.

data-type2

Specifies the data type of the column. The column is nullable.

You can specify any built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or DataLink) or a distinct type (that is not based on a DataLink). You cannot specify an array type.

If a DATE or TIME is specified, the table function must return the date or time in ISO format.

If a CCSID is specified,

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in that CCSID.
- If AS LOCATOR is specified and the CCSID of the data the locator points to is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified,

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the job (or associated graphic CCSID of the job for graphic string return values).
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the job, if the CCSID of the data the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

AS LOCATOR

Specifies that the function returns a locator to the value for the column rather than the actual value. You can specify AS LOCATOR only for a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in [“CREATE FUNCTION” on page 813](#).

LANGUAGE

The language clause specifies the language of the external program.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program at the time the function is created. The language of the program is assumed to be C if:

- The program attribute information associated with the program does not identify a recognizable language
- The program cannot be found

C

The external program is written in C.

C++

The external program is written in C++.

CL

The external program is written in CL or ILE CL.

COBOL

The external program is written in COBOL.

COBOLLE

The external program is written in ILE COBOL.

JAVA

The external program is written in JAVA. The database manager will call the user-defined function as a method in a Java class.

PLI

The external program is written in PL/I.

RPG

The external program is written in RPG.

RPGL

The external program is written in ILE RPG.

PARAMETER STYLE

Specifies the conventions used for passing parameters to and returning the values from functions:

DB2GENERAL

This parameter style is used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- The next M parameters are the result columns of the function that are specified on the RETURNS TABLE clause.

DB2GENERAL is only allowed when the LANGUAGE is JAVA.

SQL

All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- The next M parameters are the result columns of the function that are specified on the RETURNS TABLE clause.
- N parameters for indicator variables for the input parameters.
- M parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the function. The SQLSTATE returned either be:
 - the SQLSTATE from the last SQL statement executed in the external program,
 - an SQLSTATE that is assigned by the external program.

The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.

- A VARCHAR(517) input parameter for the fully qualified function name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.
- A structure (consisting of an INTEGER followed by a CHAR(n)) input and output parameter for the scratchpad, if SCRATCHPAD was specified on the CREATE FUNCTION statement.
- An INTEGER input parameter for the call type.
- A structure for the dbinfo structure, if DBINFO was specified on the CREATE FUNCTION statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the [SQL Programming](#) topic collection. For Java routines, see the [IBM Developer Kit for Java](#) topic collection.

SPECIFIC *specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “[CREATE FUNCTION](#)” on page 813.

GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a table function that is not deterministic is one that references special registers, non-deterministic functions, or a sequence in a way that affects the table function result table.

GLOBAL DETERMINISTIC

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic function results.

STATEMENT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic function results.⁹³

CONTAINS SQL, READS SQL DATA, MODIFIES SQL DATA, or NO SQL

Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1421](#). The default is READS SQL DATA. This option is ignored for parameter default expressions.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

NO SQL

Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

⁹³ The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the [Database Performance and Query Optimization](#) topic collection.

MODIFIES SQL DATA

The function can execute any SQL statement except those statements that are not supported in any function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time. CALLED ON NULL INPUT is the default.

RETURNS NULL ON NULL INPUT

Specifies that the function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows.

CALLED ON NULL INPUT

Specifies that the function is to be invoked, if any argument values are null. This specification means that the function must be coded to test for null argument values. The function can return an empty table, depending on its logic.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH

Specifies that the function is dispatched statically. All functions are statically dispatched.

NO DBINFO or DBINFO

Specifies whether additional status information is passed when the function is invoked. The default is NO DBINFO.

NO DBINFO

Specifies that no additional information is passed.

DBINFO

Specifies that the database manager should pass a structure containing status information to the function. [Table 93 on page 847](#) contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

Table 93. DBINFO fields

Field	Data Type	Description
Relational database	VARCHAR(128)	The name of the current server.
Authorization ID	VARCHAR(128)	The run-time authorization ID.

Table 93. DBINFO fields (continued)

Field	Data Type	Description
CCSID Information	INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER CHAR(8)	The CCSID information of the job. Three sets of three CCSIDs are returned. The following information identifies the three CCSIDs in each set: <ul style="list-style-type: none">• SBCS CCSID• DBCS CCSID• Mixed CCSID Following the three sets of CCSIDs is an integer that indicates which set of three sets of CCSIDs is applicable and eight bytes of reserved space. Each set of CCSIDs is for a different encoding scheme (EBCDIC, ASCII, and Unicode). If a CCSID is not explicitly specified for a parameter on the CREATE FUNCTION statement, the input string is assumed to be encoded in the CCSID of the job at the time the function is executed. If the CCSID of the input string is not the same as the CCSID of the parameter, the input string passed to the external function will be converted before calling the external program.
Target column	VARCHAR(128) VARCHAR(128) VARCHAR(128)	If a user-defined function is specified on the right-hand side of a SET clause in an UPDATE statement, the following information identifies the target column: <ul style="list-style-type: none">• Schema name• Base table name• Column name If the user-defined function is not on the right-hand side of a SET clause in an UPDATE statement, these fields are blank.
Version and release	CHAR(8)	The version, release, and modification level of the database manager.
Platform	INTEGER	The server's platform type.
Number of table function column list entries	SMALLINT	The number of non-zero entries in the table function column list specified in the "Table function column list" field below.
Reserved	CHAR(24)	Reserved for future use.

Table 93. DBINFO fields (continued)

Field	Data Type	Description
Table function column list	Pointer (16 Bytes)	<p>This field is a pointer to an array of short integers which is dynamically allocated by the database manager. Only the first n entries, where n is specified in the "Number of table function column list entries" field, are of interest, n may be equal to 0, and is less than or equal to the number of result columns defined for the function in the RETURNS TABLE clause. The values correspond to the ordinal numbers of the columns which this statement needs from the table function. A value of 1 means the first defined result column, 2 means the second defined result column, and so on. The values may be in any order. Note that n could be equal to zero for a statement that is similar to SELECT COUNT(*) FROM TABLE(TF(...)) AS QQ, where no actual column values are needed by the query.</p> <p>This array represents an opportunity for optimization. The function need not return all values for all the result columns of the table function. Only a subset of the values may be needed in a particular context, and these are the columns identified (by number) in the array. Since this optimization may complicate the function logic, the function can choose to return every defined column.</p>

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

FENCED or NOT FENCED

Specifies whether the external function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB

This parameter is allowed for compatibility with other products. It indicates whether the routine's external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN

Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

PROGRAM TYPE SUB

Specifies that the routine executes as a procedure in a service program. The external program must be a *SRVPGM object.

NO FINAL CALL or FINAL CALL

Specifies whether a separate *first call* and *final call* are made to the function. To differentiate between types of calls, the function receives an additional argument that specifies the type of call. For table functions, the *call-type* argument is always present (regardless of whether FINAL CALL or NO FINAL CALL is in effect), and it indicates first call, open call, fetch call, close call, or final call.

With NO FINAL CALL, the database manager will only make three types of calls to the table function: open, fetch and close. However, if FINAL CALL is specified, then in addition to open, fetch and close, a first call and a final call can be made to the table function.

A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resources and stores them in the scratchpad. The default is NO FINAL CALL.

NO FINAL CALL

Specifies that separate first and final calls are not made to the function. However, the open, fetch, and close calls are still made to the function, and the table function always receives an additional argument that specifies the type of call.

FINAL CALL

Specifies that separate first and final calls are made to the function. It also controls when the scratchpad is re-initialized.

The types of calls are:

First Call

Specifies the first call to the function for this reference to the function in this SQL statement.

Open Call

Specifies a call to open the table function result in this SQL statement.

Fetch Call

Specifies a call to fetch a row from the table function in this SQL statement.

Close Call

Specifies a call to close the table function result in this SQL statement.

Final Call

Specifies the last call to the function to enable the function to free resources. If an error occurs, the database manager attempts to make the final call.

A final call occurs at these times:

- *End of statement*: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- *End of transaction*: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends.

Committable operations should not be performed during a FINAL CALL, because the FINAL CALL may occur during a close invoked as part of a COMMIT operation.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, FINAL CALL, MODIFIES SQL DATA, or SCRATCHPAD. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, MODIFIES SQL DATA, SCRATCHPAD, and FINAL CALL for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL

Specifies that the database manager must not use parallelism for the function.

NO SCRATCHPAD or SCRATCHPAD

Specifies whether the function requires a static memory area.

NO SCRATCHPAD

Specifies that the function does not require a persistent memory area.

SCRATCHPAD *integer*

Specifies that the function requires a persistent memory area of length *integer*. The *integer* can range from 1 to 16,000,000. If the memory area is not specified, the size of the area is 100 bytes. If parameter style SQL is specified, a pointer is passed following the required parameters that points to a static storage area. Only 1 memory area will be allocated for the function.

The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

```
SELECT A.C1, B.C1
  FROM TABLE(UDFX(:hv1)) AS A, TABLE(UDFX(:hv1)) AS B
```

EXTERNAL

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

If *external-program-name* is not specified, the external program name is assumed to be the same as the function name.

NAME *external-program-name*

Specifies the program, service program, or Java class that will be executed when the function is invoked in an SQL statement. The name must identify a program, service program, or Java class that exists at the application server at the time the function is invoked. If the naming option is *SYS and the name is not qualified:

- The current path will be used to search for the program at the time the function is invoked.
- *LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the function.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The program, service program, or Java class need not exist at the time the function is created, but it must exist at the time the function is invoked.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statements are not allowed in the external program of the function.

CARDINALITY *bigint*

Specifies an estimate of the expected number of rows to be returned by the function for the database manager to use during optimization. *bigint* must be in the range from 0 to 9 223 372 036 854 775 807 inclusive. The database manager assumes a finite value if CARDINALITY is not specified.

A table function that returns a row every time it is called and never returns the end-of-table condition has infinite cardinality. A query that invokes such a function and requires an eventual end-of-table condition before it can return any data will not return unless interrupted. Table functions that never return the end-of-table condition should not be used in queries involving DISTINCT, GROUP BY, or ORDER BY.

NOT SECURED or SECURED

Specifies whether the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control. This option can be used for an external function that is written in C, C++, ILE RPG, ILE COBOL, ILE CL, or Java. The program or service program must exist when the CREATE FUNCTION statement is executed.

A function must be defined as secure when it is referenced in a row permission or a column mask.

***SET OPTION*-statement**

Specifies the options that will be used parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1303](#).

The following options are used when processing default value expressions: ALWCPYCTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURR RULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.

Notes

General considerations for defining user-defined functions: See [“CREATE FUNCTION” on page 813](#) for general information about defining user-defined functions.

REPLACE rules: When an external function is recreated by REPLACE:

- Any existing comment or label is discarded.
- If a different external program is specified:
 - Authorized users are not copied to the new program.
 - Journal auditing is not changed.
- Otherwise:
 - Authorized users are maintained. The object owner will not change.
 - Current journal auditing is not changed.

Creating the function: When an external function associated with an ILE external program or service program is created, an attempt is made to save the function's attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external functions subject to the following restrictions:

- The external program library must not be SYSIBM, QSYS, or QSYS2.

- The external program must exist when the CREATE FUNCTION statement is issued.

If system naming is specified and the external program name is not qualified, the external program must be found in the library list.

- The external program must be an ILE *PGM or *SRVPGM object.

If the object cannot be updated, the function will still be created.

If the external function is created in QTEMP, the catalog information is not removed when the job ends.

Invoking the function: When an external function is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the function runs in the same activation group as the calling program. ACTGRP(*NEW) is not allowed.

LANGUAGE JAVA functions always run in the default activation group (*DFTACTGRP). Caution should be used when writing MODIFIES SQL DATA Java functions. Since changes performed by the Java function are performed in the default activation group, transaction problems may occur if the invoker runs in a new activation group (*NEW).

EXTERNAL ACTION functions: When an EXTERNAL ACTION table function is invoked in a query that includes other table references, the invocation of the table function relative to the application of join or search conditions can be unpredictable. The number of times that the function is invoked and the order in which the function is invoked relative to other processing in the query can vary depending on the access plan used.

Notes for Java functions: To be able to run Java functions, you must have the IBM IBM Developer Kit for Java (5770-JV1) installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java function, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the function was run.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.
- The keywords PARAMETER STYLE DB2SQL may be used as a synonym for PARAMETER STYLE SQL.

Example

The following creates a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

Within the context of a single session, the UDF will always return the same table, and therefore it is defined as DETERMINISTIC. Note the RETURNS clause which defines the output from DOCMATCH. FINAL CALL must be specified for each table function. Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value, and is specified to help the optimizer.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
RETURNS TABLE (DOCID CHAR(16))
EXTERNAL NAME 'MYLIB/RAJIV(UDFMATCH)'
LANGUAGE C
PARAMETER STYLE SQL
NO SQL
DETERMINISTIC
NO EXTERNAL ACTION
```

```
NOT FENCED
SCRATCHPAD
FINAL CALL
DISALLOW PARALLEL
CARDINALITY 20
```

CREATE FUNCTION (sourced)

This CREATE FUNCTION (sourced) statement defines a user-defined function, based on another existing scalar or aggregate function, at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If the source function is a user-defined function, the authorization ID of the statement must include at least one of the following for the source function:

- The EXECUTE privilege on the function
- Database administrator authority

To create a sourced function, the privileges held by the authorization ID of the statement must also include at least one of the following:

- The system authority *USE to the Create Program (CRTSRVPGM) command
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

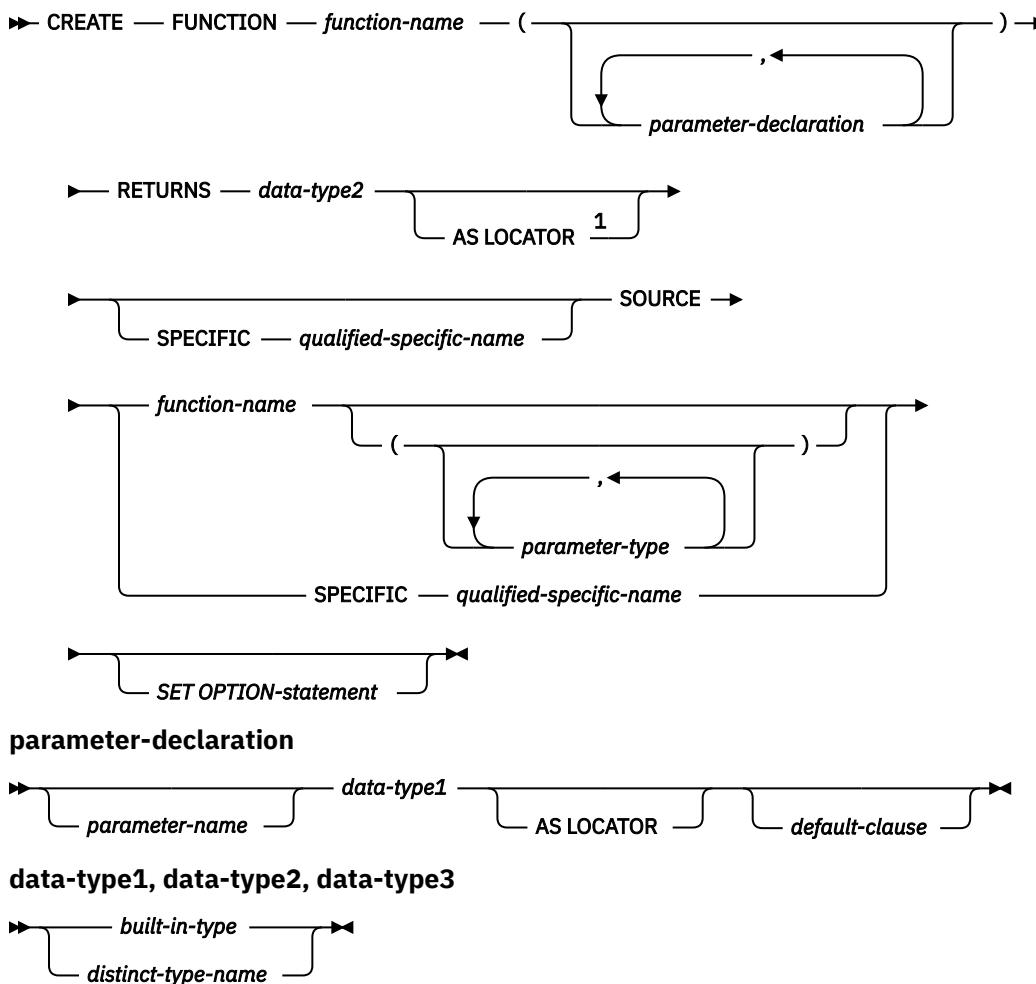

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#), [Corresponding System Authorities When](#)

Checking Privileges to a Function or Procedure, and Corresponding System Authorities When Checking Privileges to a Distinct Type.

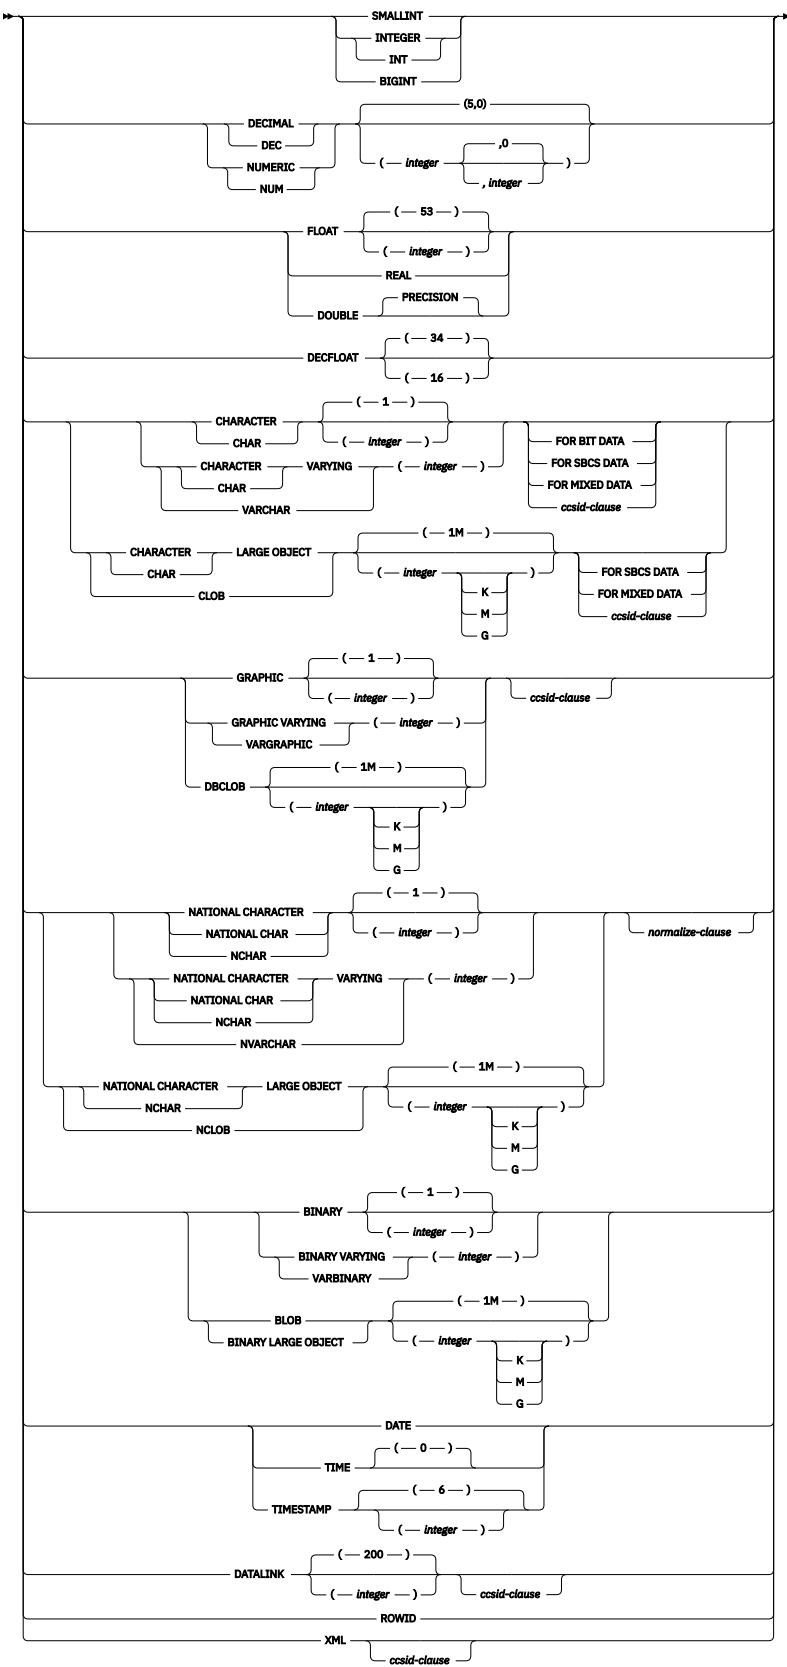

Syntax

Notes:

¹ The RETURNS, SPECIFIC, and SOURCE clauses can be specified in any order.

built-in-type

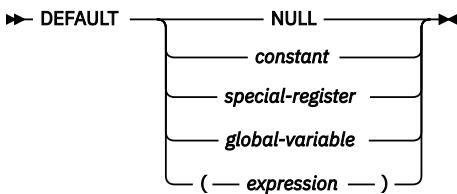

ccsid-clause

►► CCSID — *integer* —►►
 —►► *normalize-clause* —►►

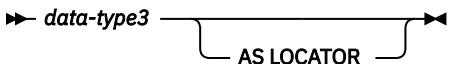

normalize-clause

default-clause

parameter-type

Description

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server unless OR REPLACE is specified.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

If the function is sourced on an existing function to enable the use of the existing function with a distinct type, the name can be the same name as the existing function. In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in [“CREATE FUNCTION” on page 813](#).

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in [“CREATE FUNCTION” on page 813](#).

parameter-name

Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type1

Specifies the data type of the parameter. The data type can be a built-in data type or a distinct data type. It cannot be an array type.

Any valid SQL data type may be used, provided that it is castable to the type of the corresponding parameter of the function identified in the SOURCE clause (for information, see “[Casting between data types](#)” on page 81). However, this checking does not guarantee that an error will not occur when the function is invoked. For more information, see [Considerations for invoking a sourced user-defined function](#).

built-in-type

The data type of the input parameter is a built-in data type. See “[CREATE TABLE](#)” on page 945 for a more complete description of each built-in data type.

distinct-type-name

The data type of the input parameter is a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). See “[CREATE TYPE \(distinct\)](#)” on page 1017 for more information.

If the name of the distinct type is specified without a schema name, the database manager resolves the schema name by searching the schemas in the SQL path.

DataLinks are not allowed for functions sourced on external functions.

If a CCSID is specified, the parameter is converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

AS LOCATOR

Specifies that the input parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the input parameter has a LOB data type or a distinct type based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “[CREATE FUNCTION](#)” on page 813.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created.

A default cannot be specified for a parameter of type array.

RETURNS

Specifies the result of the function.

data-type2

Specifies the data type of the column. The column is nullable. The data type can be a built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or a DataLink) or distinct type (that is not based on a DataLink). It cannot be an array type.

Any valid SQL data type can be used provided it is castable from the result type of the source function. (For information about casting data types, see “[Casting between data types](#)” on page 81). However, this checking does not guarantee that an error will not occur when this new function is invoked. For more information, see [Considerations for invoking a sourced user-defined function](#).

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type

based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified. The AS LOCATOR clause is not allowed for functions sourced on SQL functions.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “[CREATE FUNCTION](#)” on page 813.

SPECIFIC *qualified-specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “[CREATE FUNCTION](#)” on page 813.

SOURCE

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the following built-in functions (If a particular syntax is shown, only the indicated form cannot be specified.):

- ARRAY_AGG
- BINARY when more than one argument is specified
- BLOB when more than one argument is specified
- CARDINALITY
- CHAR when more than one argument is specified
- CLOB when more than one argument is specified
- COALESCE
- CONTAINS
- DATAPARTITIONNAME
- DATAPARTITIONNUM
- DBCLOB when more than one argument is specified
- DBPARTITIONNAME
- DBPARTITIONNUM
- DECFLOAT when more than one argument is specified
- DECIMAL when more than one argument is specified
- DECRYPT_BIN when more than one argument is specified
- DECRYPT_BINARY when more than one argument is specified
- DECRYPT_BIT when more than one argument is specified
- DECRYPT_CHAR when more than one argument is specified
- DECRYPT_DB when more than one argument is specified
- EXTRACT
- GRAPHIC when more than one argument is specified
- GREATEST
- HASH_VALUES
- HASHED_VALUE
- LAND

- LEAST
- LOR
- MAX
- MAX_CARDINALITY
- MIN
- NODENAME
- NODENUMBER
- NVL
- PARTITION
- PERCENTILE_CONT
- PERCENTILE_DISC
- POSITION
- RAISE_ERROR
- RID
- RRN
- SCORE
- SECOND when more than one argument is specified
- STRIP
- SUBSTRING
- TIMESTAMP when the second argument is an integer
- TIMESTAMP_FORMAT when more than two arguments are specified
- TO_CLOB when more than one argument is specified
- TO_DATE when more than two arguments are specified
- TO_TIMESTAMP when more than two arguments are specified
- TRANSLATE when more than one argument is specified
- TRIM
- TRIM_ARRAY
- VALUE
- VARBINARY when more than one argument is specified
- VARCHAR when more than one argument is specified
- VARGRAPHIC when more than one argument is specified
- VERIFY_GROUP_FOR_USER when more than two arguments are specified
- XMLAGG
- XMLATTRIBUTES
- XMLCOMMENT
- XMLCONCAT
- XMLDOCUMENT
- XMLELEMENT
- XMLFOREST
- XMLGROUP
- XMLNAMESPACES
- XMLPARSE
- XMLPI

- XMLROW
- XMLSERIALIZE
- XMLTEXT
- XMLVALIDATE
- XOR
- XSLTRANSFORM
- ZONED when more than one argument is specified

function-name

Identifies the function to be used as the source function by its function name. The source function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If an unqualified *function-name* is specified, the SQL path is used to locate the function. The database manager selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found, or if the database manager encounters a schema that has more than one function with this name.

function-name (parameter-type, ...)

Identifies the function to be used as the source function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified signature at the current server. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name()* is specified, the function identified must have zero parameters.

To use a built-in function as the source function, this syntax variation must be used.

function-name

Identifies the name of the source function. If an unqualified name is specified, the schemas of the SQL path are searched. Otherwise, the database manager searches for the function in the specified schema.

parameter-type,...

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision or scale attribute, use one of the following specifications:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or CCSID attribute, specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified. If AS LOCATOR is specified and a length is explicitly specified, the data type length is ignored.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “[CREATE FUNCTION](#)” on page 813.

SPECIFIC *qualified-specific-name*

Identifies the function to be used as the source function by its specific name. The *qualified-specific-name* must identify a specific function that exists in the specified schema.

SET OPTION-*statement*

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see “[SET OPTION](#)” on page 1303. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRL, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

Notes

General considerations for defining user-defined functions: See “[CREATE FUNCTION](#)” on page 813 for general information about defining user-defined functions.

Function ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the function is created exists, the *owner* of the function is that user profile.
- Otherwise, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

Function authority: If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the function.

Considerations for invoking a sourced user-defined function: When a sourced function is invoked, each argument to the function is assigned to the associated parameter defined for the function. The values are then cast (if necessary) to the data type of the corresponding parameters of the underlying function. An error can occur either in the assignment or in the cast. For example: an argument passed on input to a

function that matches the data type and length or precision attributes of the parameter for the function might not be castable if the corresponding parameter of the underlying source function has a shorter length or less precision. It is recommended that the data types of the parameters of a sourced function be defined with attributes that are less than or equal to the attributes of the corresponding parameters of the underlying function.

The result of the underlying function is assigned to the RETURNS data type of the sourced function. The RETURNS data type of the underlying function might not be castable to the RETURNS data type of the source function. This can occur when the RETURNS data type of this new source function has a shorter length or less precision than the RETURNS data type of the underlying function. For example, an error would occur when function A is invoked assuming the following functions exist. Function A returns an INTEGER. Function B is a sourced function, is defined to return a SMALLINT, and the definition references function A in the SOURCE clause. It is recommended that the RETURNS data type of a sourced function be defined with attributes that are the same or greater than the attributes defined for the RETURNS data type of the underlying function.

Considerations when the function is based on a user-defined function: If the sourced function is based directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example, assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes for function C.

The sourced function inherits the secure attribute from the user-defined function it directly based on. A sourced function based on a built-in function is always secure.

Creating the function: When a sourced function is created, a small service program object is created that represents the function. When this service program is saved and restored to another system, the attributes from the CREATE FUNCTION statement are automatically added to the catalog on that system.

Examples

Example 1: Assume that strongly typed distinct type HATSIZE is defined and is based on the built-in data type INTEGER. An AVG function could be defined to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```
CREATE FUNCTION AVG (HATSIZE)
RETURNS HATSIZE
SOURCE AVG (INTEGER)
```

The syntax of the SOURCE clause includes an explicit parameter list because the source function is a built-in function.

When distinct type HATSIZE was created, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

Example 2: After Smith created the external scalar function CENTER in his schema, there is a need to use this function, but the invocation of the function needs to accept two INTEGER arguments instead of one INTEGER argument and one DOUBLE argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
RETURNS DOUBLE
SOURCE SMITH.CENTER (INTEGER, DOUBLE);
```

CREATE FUNCTION (SQL scalar)

This CREATE FUNCTION (SQL scalar) statement creates an SQL function at the current server. The function returns a single result.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- The following system authorities:
 - *USE to the Create Service Program (CRTSRVPGM) command or
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

If the SECURED attribute is specified, or the function is secure and OR REPLACE is specified:

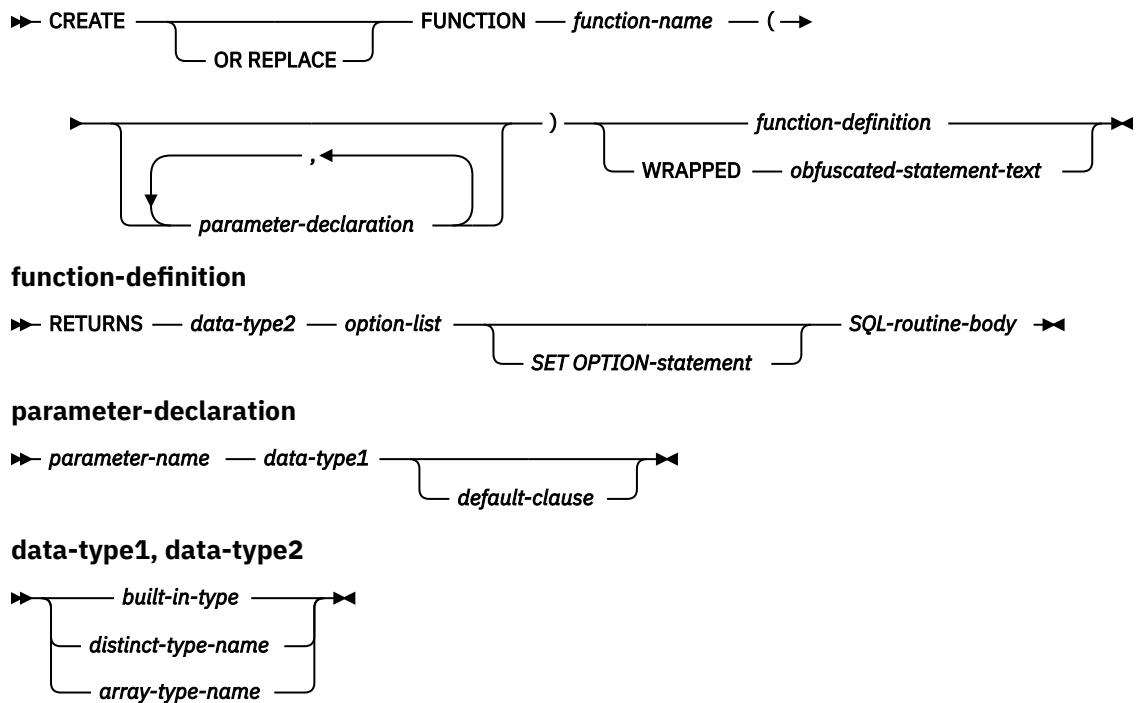

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority” on page 15](#).

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

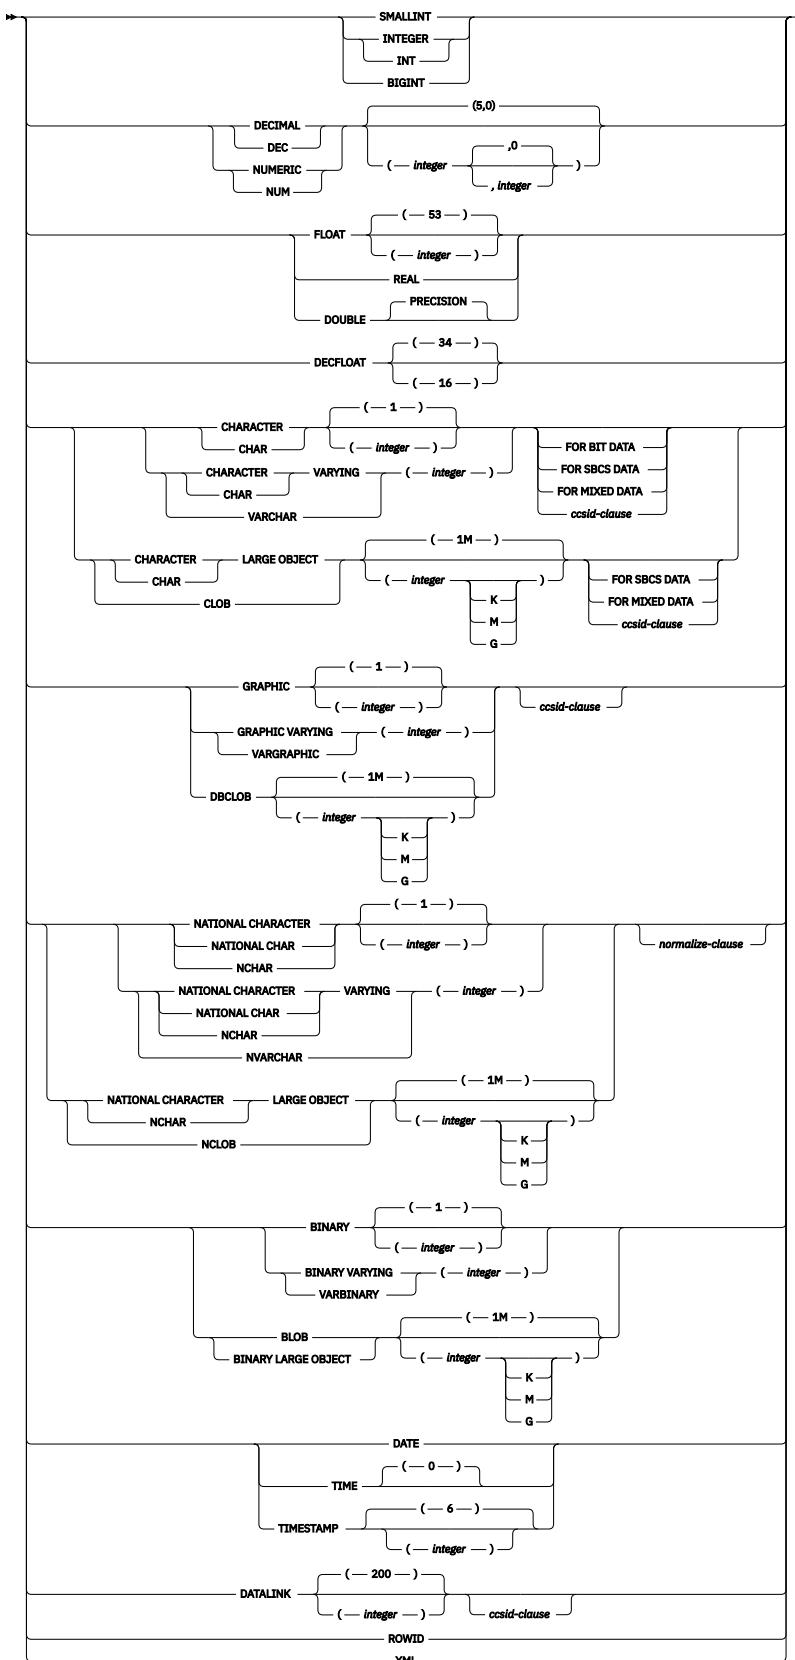

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the service program object associated with the function
 - All authorities needed to DROP the function
 - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

option-list

Notes:

- ¹ This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

SQL-routine-body

►► *SQL-control-statement* ►►

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition

for the function does not exist at the current server. To replace an existing function, the *specific-name* and *function-name* of the new definition must be the same as the *specific-name* and *function-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server unless OR REPLACE is specified.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in [“CREATE FUNCTION” on page 813](#).

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. For more information, see Defining the parameters in [“CREATE FUNCTION” on page 813](#).

parameter-name

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct data type.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see [“CREATE TABLE” on page 945](#).

distinct-type-name

Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see [“CREATE TYPE \(distinct\)” on page 1017](#).

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

array-type-name

Specifies an array type.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter is converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

A parameter that is an array of XML or LOB type is read only.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created.

A default cannot be specified for a parameter of type array.

RETURNS

Specifies the result of the function.

data-type2

Specifies the expression that is to be returned for the function. The result data type of the expression must be assignable (using storage assignment rules) to the data type that is defined in the RETURNS clause. For more information, see “[Assignments and comparisons](#)” on page 83.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC), a distinct type, or an array type.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified, the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

LANGUAGE SQL

Specifies that this is an SQL function.

SPECIFIC *specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “[CREATE FUNCTION](#)” on page 813.

PROGRAM NAME *external-program-name*

Specifies the unqualified name of the service program to be created for the function. *external-program-name* must be a valid system name.

GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a function that is not deterministic is one that generates random numbers.

A function that is not deterministic might return incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

NOT DETERMINISTIC should be specified if the function contains a reference to a special register, a non-deterministic function, or a sequence.

GLOBAL DETERMINISTIC

Specifies that the function always returns the same result each time that the function is invoked with the same input arguments. The database manager uses this information during optimization

of SQL statements. The query optimizer may choose to cache global deterministic scalar function results.⁹⁴ An example of a global deterministic function is a function that calculates the square root of the input argument.

STATEMENT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic scalar function results.⁹⁵ An example of a statement deterministic function is a function that performs currency conversion.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

CONTAINS SQL, READS SQL DATA, or MODIFIES SQL DATA

Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see Appendix B, “Characteristics of SQL statements,” on page 1421. The default is READS SQL DATA. This option applies to any parameter default expressions.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

MODIFIES SQL DATA

The function can execute any SQL statement except those statements that are not supported in any function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON INPUT

Specifies that the function is not invoked if any of the input arguments is null. The result is the null value.

⁹⁴ If the result of the function contains sensitive data, consider using STATEMENT DETERMINISTIC or the DETERMINISTIC_UDF_SCOPE QAQQINI option or create the function NOT DETERMINISTIC to prevent inadvertent access to the result. For more information, see the [Database Performance and Query Optimization](#) topic collection.

⁹⁵ The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the [Database Performance and Query Optimization](#) topic collection.

CALLED ON NULL INPUT

Specifies that the function is to be invoked if any or all argument values are null. This specification means that the function must be coded to test for null argument values. The function can return a null or nonnull value.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH

Specifies that the function is dispatched statically. All functions are statically dispatched.

DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE

Indicates whether the function is created so it can be debugged by the Unified Debugger. If DEBUG MODE is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

DISALLOW DEBUG MODE

The function cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is DISALLOW, the function can be subsequently altered to change the debug mode attribute.

ALLOW DEBUG MODE

The function can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is ALLOW, the function can be subsequently altered to change the debug mode attribute.

DISABLE DEBUG MODE

The function cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is DISABLE, the function cannot be subsequently altered to change the debug mode attribute.

If FENCED or ALLOW PARALLEL is specified for the function, the DEBUG MODE option will be ignored. DISALLOW DEBUG MODE will be used.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the function cannot be debugged by the Unified Debugger, but may be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

FENCED or NOT FENCED

Specifies whether the SQL function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, or MODIFIES SQL DATA. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, and MODIFIES SQL DATA for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL

Specifies that the database manager must not use parallelism for the function.

CONCURRENT ACCESS RESOLUTION

Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

DEFAULT

Specifies that the concurrent access resolution is not explicitly set for this function. The value that is in effect when the function is invoked will be used.

WAIT FOR OUTCOME

Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SYSTEM_TIME SENSITIVE

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

YES

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NO

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NOT SECURED or SECURED

Specifies whether the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

A function must be defined as secure when it is referenced in a row permission or a column mask.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

SET OPTION-*statement*

Specifies the options that will be used to create the function. These options also apply to any default value expressions. For example, to create a debuggable function, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

The default values for the options depend on the options in effect at create time. For information about the , see “[SET OPTION](#)” on page 1303.

The options CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. CLOSQLCSR(*ENDMOD) is the default for SQL scalar functions. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRL, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single *SQL-procedure-statement*, including a compound statement. See “[SQL control statements](#)” on page 1359 for more information about defining SQL functions.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statement is not allowed in a function.

If the *SQL-routine-body* is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is called.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining user-defined functions: For general information about defining user-defined functions, see “[CREATE FUNCTION](#)” on page 813.

SQL path and function resolution: Resolution of function invocations inside the function body is done according to the SQL path that is in effect for the CREATE FUNCTION statement and does not change after the function is created.

Function ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the function is created exists, the *owner* of the function is that user profile.
- Otherwise, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

Function authority: If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the function.

REPLACE rules: When a function is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

If the function is replaced and the function signature or result data type is altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

Creating the function: When an SQL function is created, the database manager creates a temporary source file that will contain C source code with embedded SQL statements. A *SRVPGM object is then created using the CRTSRVPGM command. The SQL options used to create the service program are the options that are in effect at the time the CREATE FUNCTION statement is executed. The service program is created with ACTGRP(*CALLER).

When an SQL function is created, the function's attributes are stored in the created service program object. If the *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

If the PROGRAM NAME clause is provided, its name is used for the creation of the service program object. Otherwise, the specific name is used to determine the name of the source file member and *SRVPGM object. If the specific name is a valid system name, it will be used as the name of member and program. If the member already exists, it will be overlaid. If a program already exists in the specified library, a unique name is generated using the rules for generating system table names. If the specific name is not a valid system name, a unique name is generated using the rules for generating system table names.

Invoking the function: When an SQL function is invoked, it runs in the activation group of the calling program.

If a function is specified in the *select-list* of a *select-statement* and if the function specifies EXTERNAL ACTION or MODIFIES SQL DATA, the function will only be invoked for each row returned. Otherwise, the UDF may be invoked for rows that are not selected.

Inline functions: When an SQL scalar function is inlined, instead of invoking the function as part of a query, the *expression* in the RETURN statement of the function may be copied (inlined) into the query itself. Such a function is called an *inline function*. A scalar function is an *inline function* if:

- The SQL function is global deterministic.
- The *SQL-routine-body* contains only a RETURN statement.
- No input parameter is an array type.
- The data type of the result is not XML or an array type.
- All objects referenced in the function exist when the function is created.
- The *SQL-routine-body* does not contain a common table expression that references an input parameter.
- The *SQL-routine-body* does not contain a nested table expression without a preceding LATERAL keyword that references an input parameter.

An *inline function* is only copied (inlined) into a query if:

- The query is eligible for the SQL Query Engine (SQE).
- The function references an object and the authority attributes of the function and the query are compatible based on one of the following conditions:
 - The function is defined to run under the user's authority (*USER).
 - The query is running under the owner's authority (*OWNER) and the owner of the query is the same as the owner of the function.
 - The query is running under the user's authority (*USER), and the user or the user's group profile is the same as the owner of the function.

Note: If the function is defined as FENCED, the query must not use adopted authority. If the query runs under the owner's authority (*OWNER) and the function runs under the user's authority (*USER), the owner of the query must be the same as the user or the user's group profile.

When a function is inlined, some of the options specified when the function was created are ignored:

- PARALLEL or NOT PARALLEL
- MODIFIES SQL DATA
- Commitment control level
- CONCURRENT ACCESS RESOLUTION
- ALWCPYDTA
- ATOMIC or NOT ATOMIC
- USRPRF

If a function is inlined and it contains a reference to a special register, the value of the special register will be the same as other references to the same special register in the query.

Returning an array from a function: If the return type of a function is an array type, the function can only be invoked from within an SQL function or SQL procedure routine body in one of the following contexts:

- the *select-list* of a SELECT INTO
- the *select-list* of a DECLARE CURSOR
- the *select-list* of a scalar subselect on the right side of a SET statement

A *select-list* that contains a function that returns an array type cannot use the DISTINCT keyword. A query that contains this select list cannot use UNION, EXCEPT, or INTERSECT.

Obfuscated statements: A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the function is created from an obfuscated statement are ignored. A function that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Setting of the default value: Parameters of a function that are defined with a default value are set to their default value when the function is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

Dependent objects: An SQL routine is dependent on objects that are referenced in the *SQL-routine-body*. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference in the *SQL-routine-body* is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Example 1: Define a scalar function that returns the tangent of a value using the existing SIN and COS built-in functions.

```
CREATE FUNCTION TAN
  (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X)
```

Notice that a parameter name (X) is specified for the input parameter to function TAN. The parameter name is used within the body of the function to refer to the input parameter. The invocations of the SIN and COS functions, within the body of the TAN user-defined function, pass the parameter X as input.

Example 2: Define a scalar function that returns a date formatted as *mm/dd/yyyy* followed by a string of up to 3 characters:

```
CREATE FUNCTION BADPARM
  (INP1 DATE,
   USA VARCHAR(3))
```

```
RETURNS VARCHAR(20)
LANGUAGE SQL
CONTAINS SQL
NO EXTERNAL ACTION
DETERMINISTIC
RETURN CHAR(INP1,USA)CONCAT USA
```

Assume that the function is invoked as in the following statement:

```
SELECT BADPARM(BIRTHDATE,'ISO')
      FROM EMPLOYEE WHERE EMPNO='000010'
```

The result is '08/24/1933ISO'. Notice that parameter names (INP1 and USA) are specified for the input parameters to function BADPARM. Although there is an input parameter named USA, the instance of USA in the parameter list for the CHAR function is taken as the keyword parameter for the built-in CHAR function and not the parameter named USA.

CREATE FUNCTION (SQL table)

This CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a single result table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- The following system authorities:
 - *USE to the Create Service Program (CRTSRVPGM) command or
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

If the SECURED attribute is specified, or the function is secure and OR REPLACE is specified:

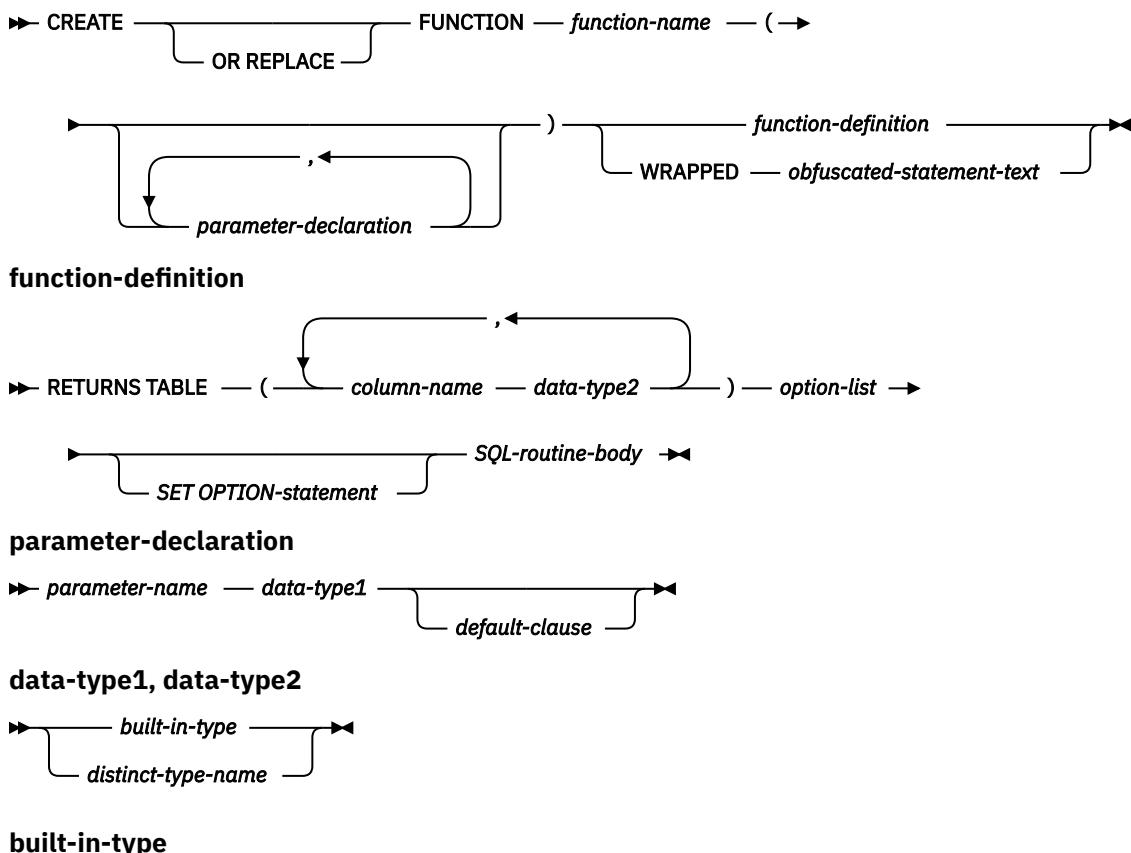

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority” on page 15](#).

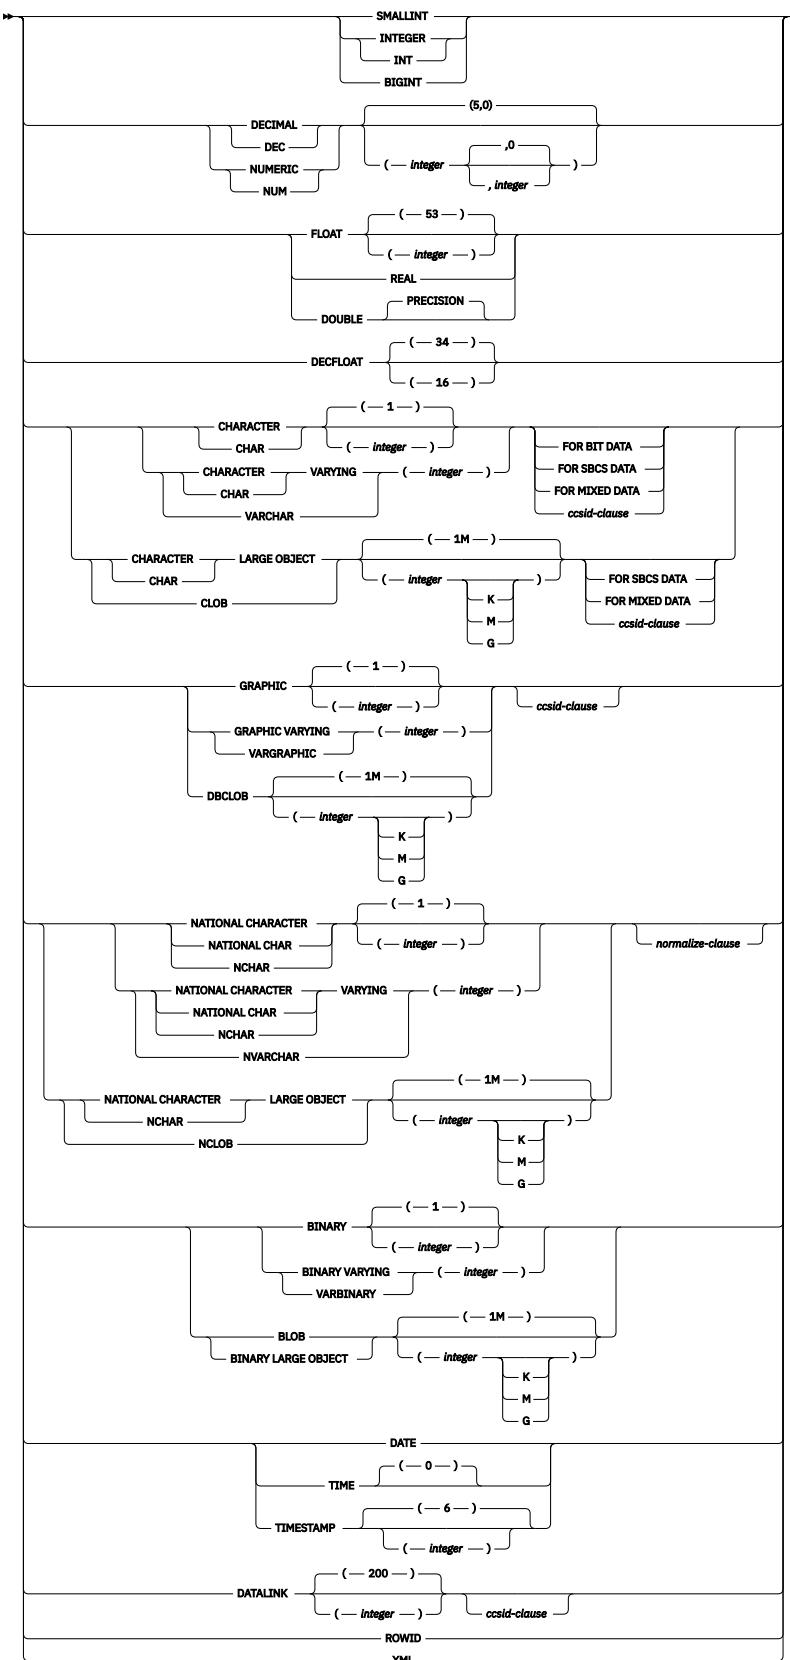

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the service program object associated with the function
 - All authorities needed to DROP the function
 - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

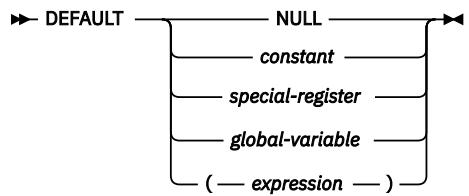

ccsid-clause

►► CCSID — *integer* —►►
 —►► *normalize-clause* —►►

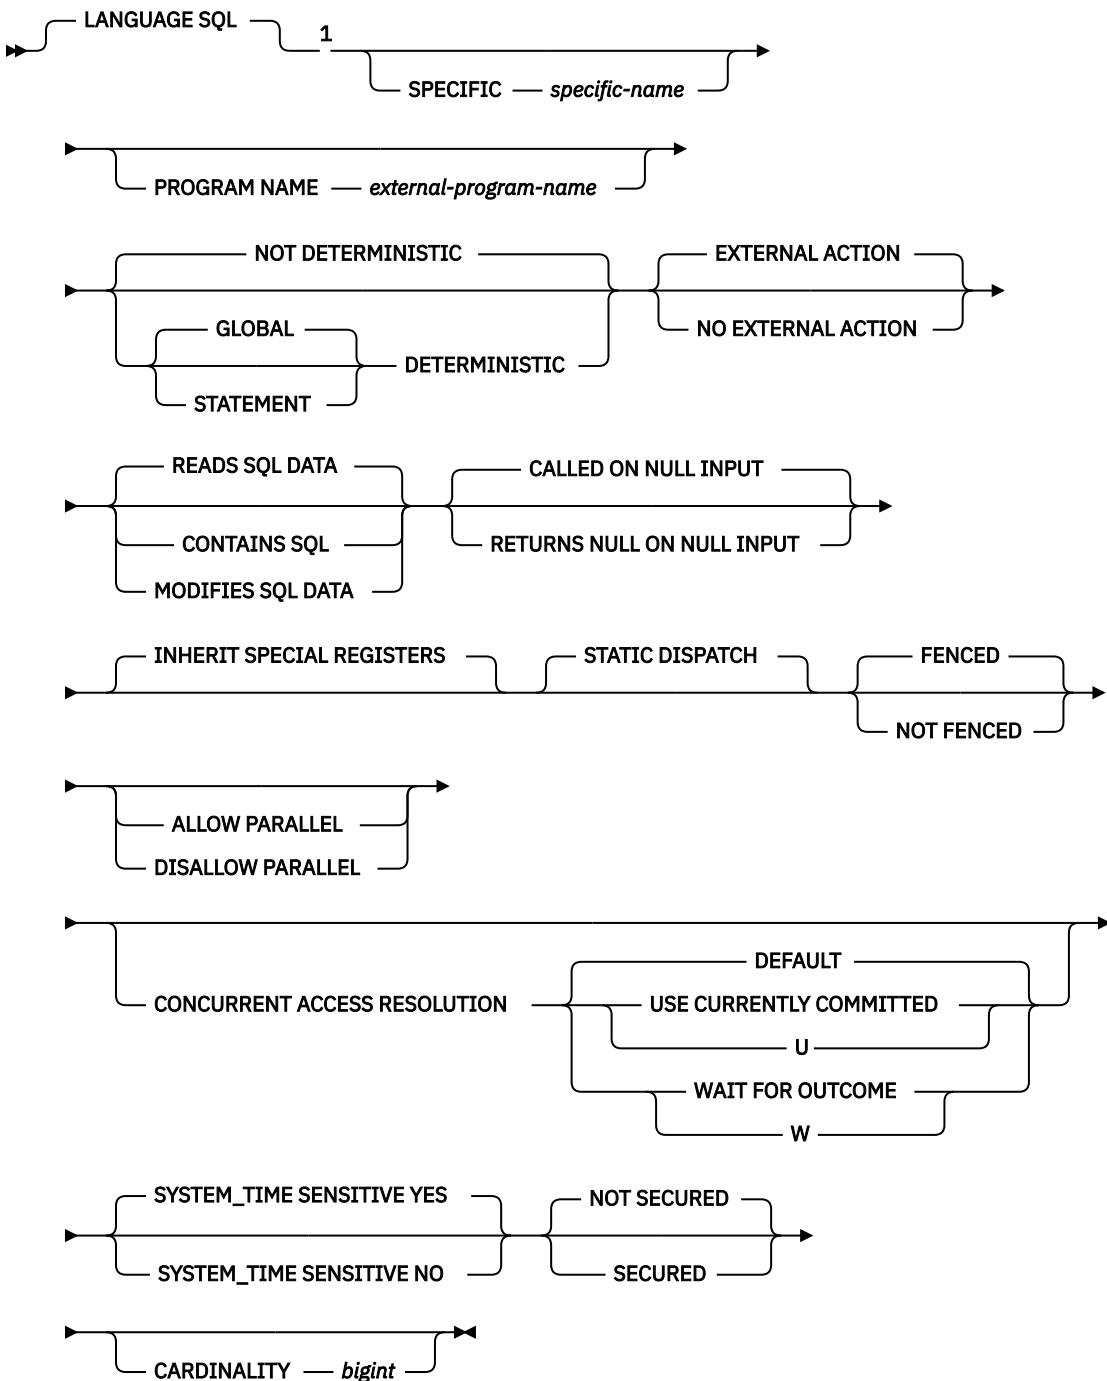

normalize-clause

default-clause

option-list

Notes:

¹ This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

SQL-routine-body

►— *SQL-control-statement* ►

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception

that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the *specific-name* and *function-name* of the new definition must be the same as the *specific-name* and *function-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server unless OR REPLACE is specified.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in [“CREATE FUNCTION” on page 813](#).

(*parameter-declaration*,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. For more information, see Defining the parameters in [“CREATE FUNCTION” on page 813](#).

parameter-name

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct data type.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see [“CREATE TABLE” on page 945](#).

distinct-type-name

Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see [“CREATE TYPE \(distinct\)” on page 1017](#).

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in [“Expressions” on page 147](#), that does not include an aggregate function or column name. If a

default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created.

RETURNS TABLE

Specifies the output table of the function.

Assume the number of parameters is N . There must be no more than $8000-N$ columns.

column-name

Specifies the name of a column of the output table. Do not specify the same name more than once.

data-type2

Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC) or a distinct type. When the function is invoked the results are assigned to these data types (using storage assignment rules).

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified and the function is not referenced in a view, the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

If a CCSID is not specified and the function is referenced in a view, the return data is converted to the CCSID of the associated view column. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

LANGUAGE SQL

Specifies that this is an SQL function.

SPECIFIC *specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “[CREATE FUNCTION](#)” on page 813.

PROGRAM NAME *external-program-name*

Specifies the unqualified name of the service program to be created for the function. *external-program-name* must be a valid system name.

GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a table function that is not deterministic is one that references special registers, non-deterministic functions, or a sequence in a way that affects the table function result table.

GLOBAL DETERMINISTIC

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic function results.

STATEMENT DETERMINISTIC

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic function results.⁹⁶

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

CONTAINS SQL, READS SQL DATA, or MODIFIES SQL DATA

Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1421](#). The default is READS SQL DATA. This option applies to any parameter default expressions.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

MODIFIES SQL DATA

The function can execute any SQL statement except those statements that are not supported in any function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT

Specifies that the function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON NULL INPUT is the default.

⁹⁶ The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the [Database Performance and Query Optimization](#) topic collection.

CALLED ON NULL INPUT

Specifies that the function is to be invoked if any argument values are null. This specification means that the function must be coded to test for null argument values. The function can return an empty table, depending on its logic.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH

Specifies that the function is dispatched statically. All functions are statically dispatched.

FENCED or NOT FENCED

Specifies whether the SQL function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, or MODIFIES SQL DATA, or if this is a pipelined table function. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, and MODIFIES SQL DATA for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL

Specifies that the database manager must not use parallelism for the function.

CONCURRENT ACCESS RESOLUTION

Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

DEFAULT

Specifies that the concurrent access resolution is not explicitly set for this function. The value that is in effect when the function is invoked will be used.

WAIT FOR OUTCOME

Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SYSTEM_TIME SENSITIVE

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

YES

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NO

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NOT SECURED or SECURED

Specifies whether the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

A function must be defined as secure when it is referenced in a row permission or a column mask.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

CARDINALITY *bigint*

This optional clause provides an estimate of the expected number of rows to be returned by the function for optimization purposes. Valid values for integer range from 0 to 9 223 372 036 854 775 807 inclusive.

If the CARDINALITY clause is not specified for a table function, the database manager will assume a finite value as a default.

A table function that returns a row every time it is called and never returns the end-of-table condition has infinite cardinality. A query that invokes such a function and requires an eventual end-of-table condition before it can return any data will not return unless interrupted.

SET OPTION-*statement*

Specifies the options that will be used to create the function. These options also apply to any default value expressions. For example, to create a debuggable function, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1303](#).

The options CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. CLOSQLCSR(*ENDACTGRP) is always used for SQL table functions. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single SQL statement, including a compound statement. See [“SQL control statements” on page 1359](#) for more information about defining SQL functions.

A non-pipelined table function must contain exactly one RETURN statement. A pipelined table function must contain at least one RETURN statement. The RETURN statement must be executed when the function is invoked.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK and SET TRANSACTION statement is not allowed in a function.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining user-defined functions: See “[SQL control statements](#)” on page [1359](#) for general information about defining user-defined functions.

Function ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the function is created exists, the *owner* of the function is that user profile.
- Otherwise, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

Function authority: If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the function.

Pipelined and non-pipelined functions: There are two types of SQL table functions. A table function which does not contain any PIPE statements within the *SQL-routine-body* is a non-pipelined table function. It contains one RETURN statement which returns a table. A pipelined table function is a table function which contains one or more RETURN statements with no return values and zero or more PIPE statements within the *SQL-routine-body*. It returns a table a row at a time. The two types of table functions are invoked in exactly the same way.

A PIPE statement returns a result row from the table function. To get the next row, control returns in the *SQL-routine-body* to the statement following the PIPE statement.

REPLACE rules: When a function is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

If the function is replaced and the function signature or result data types are altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

Creating the function: When an SQL function is created, the database manager creates a temporary source file that will contain C source code with embedded SQL statements. A *SRVPGM object is then created using the CRTSRVPGM command. The SQL options used to create the service program are the options that are in effect at the time the CREATE FUNCTION statement is executed. The service program is created with ACTGRP(*CALLER).

When an SQL function is created, the function's attributes are stored in the created service program object. If the *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

If the PROGRAM NAME clause is provided, its name is used for the creation of the service program object. Otherwise, the specific name is used to determine the name of the source file member and *SRVPGM object. If the specific name is a valid system name, it will be used as the name of member and program. If the member already exists, it will be overlaid. If a program already exists in the specified library, a unique name is generated using the rules for generating system table names. If the specific name is not a valid system name, a unique name is generated using the rules for generating system table names.

Invoking the function: When an SQL function is invoked, it runs in the activation group of the calling program.

EXTERNAL ACTION functions: When an EXTERNAL ACTION table function is invoked in a query that includes other table references, the invocation of the table function relative to the application of join or search conditions can be unpredictable. The number of times that the function is invoked and the order in which the function is invoked relative to other processing in the query can vary depending on the access plan used.

Inline functions: When an SQL table function is inlined, instead of invoking the function as part of a query, the *fullselect* in the RETURN statement of the function may be copied (inlined) into the query itself. Such a function is called an *inline function*. A table function is an *inline function* if:

- The SQL function is defined as NO EXTERNAL ACTION.
- The *SQL-routine-body* contains only a RETURN statement.
- No column in the result table is the XML data type.
- All objects referenced in the function exist when the function is created.
- The *SQL-routine-body* does not contain a common table expression that references an input parameter.

An *inline function* is only copied (inlined) into a query if:

- The query is eligible for the SQL Query Engine (SQE).
- The function does not reference a table on a different server.
- The function references an object and the authority attributes of the function and the query are compatible based on one of the following conditions:
 - The function is defined to run under the user's authority (*USER).
 - The query is running under the owner's authority (*OWNER) and the owner of the query is the same as the owner of the function.
 - The query is running under the user's authority (*USER), and the user or the user's group profile is the same as the owner of the function.

Note: If the function is defined as FENCED, the query must not use adopted authority. If the query runs under the owner's authority (*OWNER) and the function runs under the user's authority (*USER), the owner of the query must be the same as the user or the user's group profile.

When a function is inlined, some of the options specified when the function was created are ignored:

- PARALLEL or NOT PARALLEL
- MODIFIES SQL DATA
- Commitment control level
- CONCURRENT ACCESS RESOLUTION
- ALWCPYDTA
- ATOMIC or NOT ATOMIC
- USRPRF

If a function is inlined and it contains a reference to a special register, the value of the special register will be the same as other references to the same special register in the query.

Obfuscated statements: A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the function is created from an obfuscated statement are ignored. A function that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Dependent objects: An SQL routine is dependent on objects that are referenced in the *SQL-routine-body*. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference

in the *SQL-routine-body* is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Define a table function that returns the employees in a specified department number.

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
RETURNS TABLE (EMPNO CHAR(6),
                LASTNAME VARCHAR(15),
                FIRSTNAME VARCHAR(12))
LANGUAGE SQL
READS SQL DATA
NO EXTERNAL ACTION
DETERMINISTIC
DISALLOW PARALLEL
RETURN
SELECT EMPNO, LASTNAME, FIRSTNAME
      FROM EMPLOYEE
     WHERE EMPLOYEE.WORKDEPT =DEPTEMPLOYEES.DEPTNO
```

CREATE INDEX

The CREATE INDEX statement creates an index on a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Create Logical File (CRTLF) command
 - *CHANGE to the data dictionary if the library into which the index is created is an SQL schema with a data dictionary
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- For the referenced table:
 - The INDEX privilege on the table
 - The USAGE privilege on the schema containing the table
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the index is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

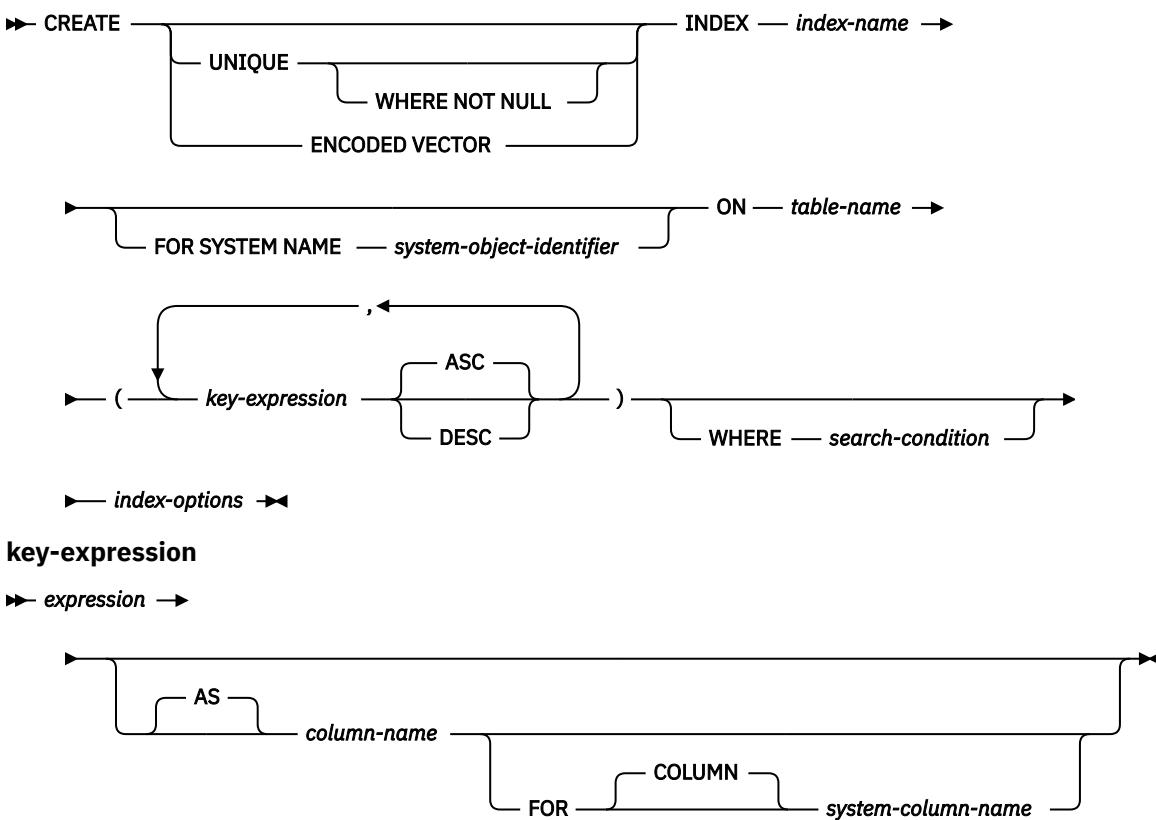

- The system authority *ADD to the user profile with that name
- Database administrator authority

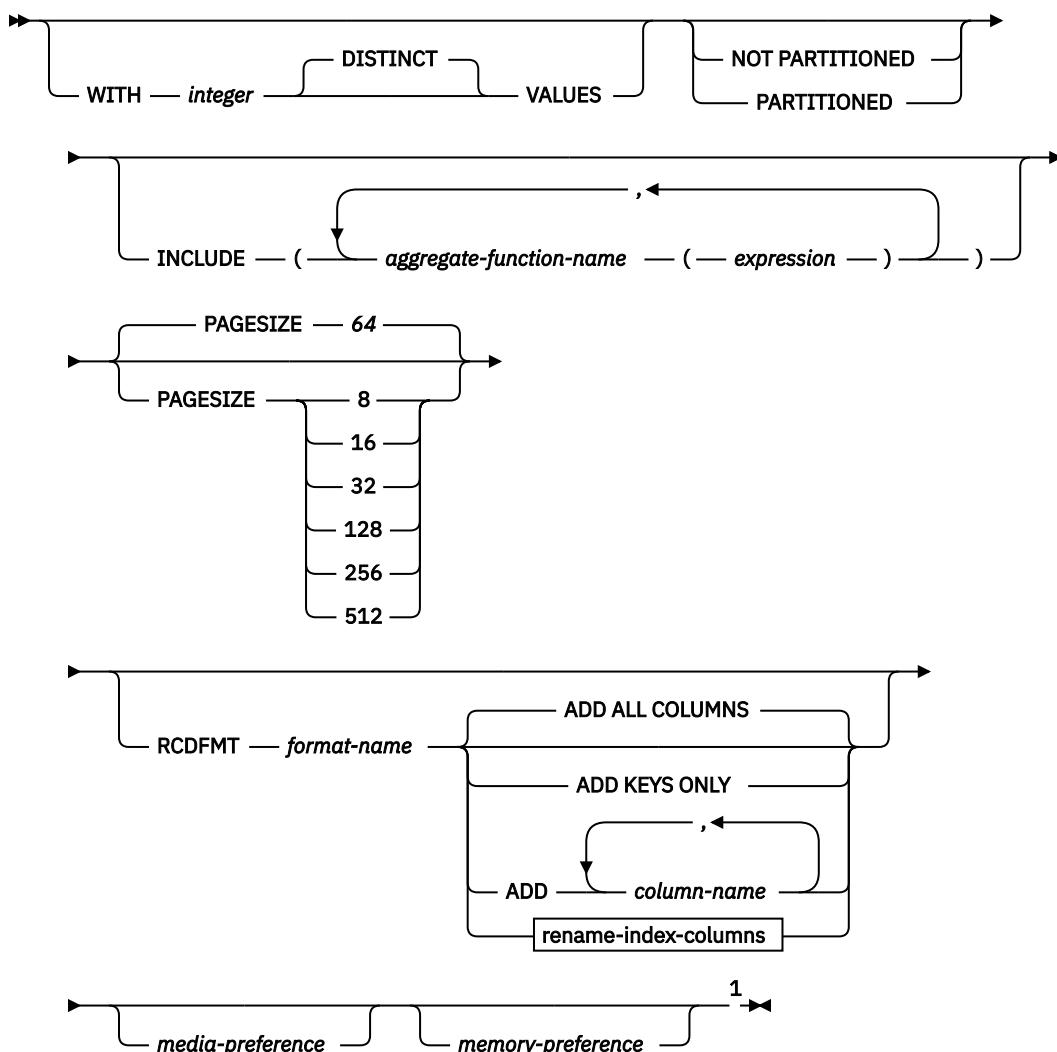

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

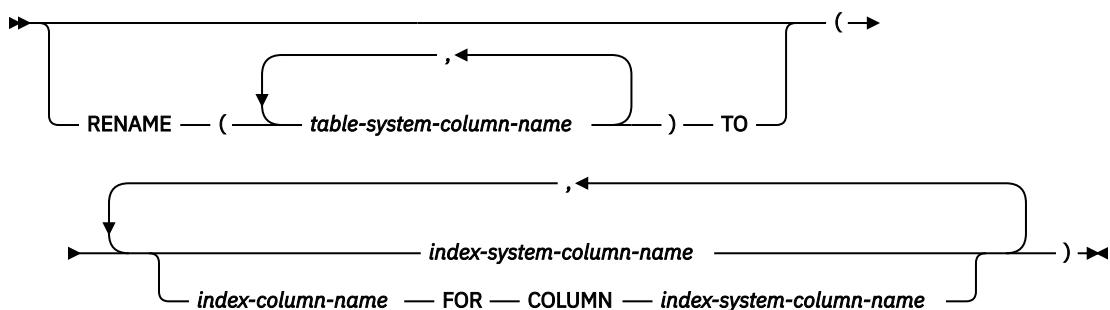

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

rename-index-columns

media-preference

►► UNIT ANY
►► UNIT SSD

memory-preference

►► KEEP IN MEMORY — NO
►► YES

Notes:

¹ The *index-options* may be specified in any order.

Description

UNIQUE

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

UNIQUE WHERE NOT NULL

Prevents the table from containing two or more rows with the same value of the index key, where all null values for a column are not considered equal. Multiple null values in a column are allowed. Otherwise, this is identical to UNIQUE.

ENCODED VECTOR

Specifies that the resulting index will be an encoded vector index (EVI).

An encoded vector index cannot be used to ensure an ordering of rows. It is used by the database manager to improve the performance of queries. For more information, see the [Database Performance and Query Optimization](#) topic collection.

index-name

Names the index. The name, including the implicit or explicit qualifier, must not be the same as an index, table, view, alias, or file that already exists at the current server.

If SQL names were specified, the index will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the index name will be created in the schema that is specified by the qualifier. If not qualified, the index name will be created in the same schema as the table over which the index is created.

If the index name is not a valid system name and the FOR SYSTEM NAME clause is not used, Db2 for i will generate a system name. For information about the rules for generating a name, see “[Rules for Table Name Generation](#)” on page 994.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the index. *system-object-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *index-name* must not be a valid system object name.

ON *table-name*

Identifies the table on which the index is to be created. The *table-name* must identify a base table (not a view) that exists at the current server.

If the table is a partitioned table, an alias may be specified which identifies a single partition. The created index will then only be created over the specified partition.

key-expression

Identifies a column or expression that will be part of the index key.

The number of keys defined for the index must not exceed 120, and the sum of their byte lengths must not exceed 32766-*n*, where *n* is the number of keys specified that allow nulls.

expression

If *expression* contains only a *column-name*, it must be an unqualified name that identifies a column of the table. *expression* must contain a column reference. The same *column-name* cannot be specified more than once if:

- a WHERE clause, INCLUDE clause, or RCDFMT clause is specified,
- an expression is defined as part of an index key, or

- a column is renamed using the AS clause.

If the *expression* is not a column name, the *expression* must not reference a column that contains a field procedure.

A *column-name* must not identify a LOB, XML, or DATALINK column, or a distinct type based on a LOB, XML, or DATALINK column. If the *expression* is not a column name, any intermediate result expression and the final result expression must not be a DATALINK, LOB, or XML data type. It must not contain any of the following:

- Subqueries
- Aggregate functions
- TRY_CAST specification
- Variables
- Global variables
- Parameter markers
- Special registers
- Sequence references
- OLAP specifications
- ROW CHANGE expressions
- REGEXP_LIKE predicate
- User-defined functions other than functions that were implicitly generated with the creation of a strongly typed distinct type
- Any function that is not deterministic
- The following built-in scalar functions:

ATAN2	DLURLSERVER	JSON_QUERY	REPLACE
BSON_TO_JSON	DLVALUE	JSON_TO_BSON	ROUND_TIMESTAMP
CARDINALITY	ENCRYPT_AES	JSON_VALUE	RPAD
CONTAINS	ENCRYPT_AES256	LOCATE_IN_STRING	SCORE
CURDATE	ENCRYPT_RC2	LPAD	SOUNDEX
CURTIME	ENCRYPT_TDES	MAX_CARDINALITY	TABLE_NAME
DATAPARTITIONNAME	GENERATE_UNIQUE	MONTHNAME	TABLE_SCHEMA
DATAPARTITIONNUM	GETHINT	MONTHS_BETWEEN	TIMESTAMP_FORMAT
DAYNAME	HASH	NEXT_DAY	TIMESTAMPDIFF
DBPARTITIONNAME	HASH_MD5	NOW	TIMESTAMPDIFF_BIG
DECRYPT_BINARY	HASH_SHA1	OVERLAY	TRUNC_TIMESTAMP
DECRYPT_BIT	HASH_SHA256	RAISE_ERROR	VARCHAR_FORMAT
DECRYPT_CHAR	HASH_SHA512	RAND	VERIFY_GROUP_FOR_USER
DECRYPT_DB	IDENTITY_VAL_LOCAL	REGEXP_COUNT	WEEK_ISO
DIFFERENCE	INSERT	REGEXP_INSTR	WRAP
DLURLCOMPLETE ¹	INTERPRET	REGEXP_REPLACE	XMLEPARSE
DLURLPATH	JSON_ARRAY	REGEXP_SUBSTR	XMLVALIDATE
DLURLPATHONLY	JSON_OBJECT	REPEAT	XSLTRANSFORM
DLURLSCHEME			

¹ For DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.

column-name

Names a column of the index. Do not use the same name for more than one column of the index or for a *system-column-name* of the index.

If the *expression* is not a column name and is not named, a name will be generated for the index key column. The name will be SQLIXxxxx, where xxxx is a number that makes the column name unique for the index.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the index or for a column-name of the index.

If the *system-column-name* is not specified, and the *column-name* is not a valid *system-column-name*, a system column name is generated. The name will be SQLIXxxxx, where xxxx is a number that makes the column name unique for the index.

ASC

Specifies that the index entries are to be kept in ascending order of the column values. ASC is the default.

DESC

Specifies that the index entries are to be kept in descending order of the column values.

Ordering is performed in accordance with the comparison rules described in “[Assignments and comparisons](#)” on page 83. The null value is higher than all other values.

WHERE *search-condition*

Specifies the condition to apply for a row to be included in the index. The *search-condition* cannot contain a predicate with a subquery. It must not contain any of the items listed as restrictions for *key-expression*.

WITH *integer* DISTINCT VALUES

Specifies the estimated number of distinct key values. This clause may be specified for any type of index.

For encoded vector indexes this is used to determine the initial size of the codes assigned to each distinct key value. Only 1, 2, and 4 byte codes are used. If the INCLUDE clause is not specified, the default value is 255 (a 1-byte code). Otherwise, a 4-byte code is used. During the create or rebuild of the index if the number of distinct values exceeds the maximum supported by the size of the code, the size of the code is increased.

For non-encoded vector indexes, this clause is ignored.

PARTITIONED

Specifies that an index partition should be created for each data partition defined for the table using the specified columns. The *table-name* must identify a partitioned table. If the index is unique, the columns of the index must be the same or a superset of the columns of the data partition key.

PARTITIONED is the default if the index is not unique and the table is partitioned.

NOT PARTITIONED

Specifies that a single index should be created that spans all of the data partitions defined for the table. The *table-name* must identify a partitioned table. NOT PARTITIONED is the default if the index is unique and the table is partitioned. An index on a table that is not partitioned is also by default not partitioned.

If an encoded vector index is specified, NOT PARTITIONED is not allowed.

PAGESIZE

Specifies the logical page used for the index in kilobytes. Indexes with larger logical page sizes are typically more efficient when scanned during query processing. Indexes with smaller logical page sizes are typically more efficient for simple index probes and individual key look ups.

The default value for PAGESIZE is determined by the length of the key and has a minimum value of 64.

If an encoded vector index is specified, PAGESIZE is not allowed.

INCLUDE

Specifies aggregate function expressions to be included in the index. These aggregates make it possible for the index to be used directly to return aggregate results for a query. INCLUDE is only allowed for an encoded vector index.

aggregate-function-name (expression)

The aggregate function name must be one of the built-in functions AVG, COUNT, COUNT_BIG, SUM, STDDEV, STDDEV_SAMP, VARIANCE, or VARIANCE_SAMP. The DISTINCT keyword must not be specified. The *expression* argument of the aggregate function must not contain any of the items listed as restrictions for *key-expression*.

RCDFMT *format-name*

An unqualified name that designates the IBM i record format name of the index. A *format-name* is a system identifier.

If the INCLUDE keyword is specified, RCDFMT is not allowed.

ADD ALL COLUMNS

Specifies that all non-hidden columns of *table-name* will be added to the format for the index. All the columns will be defined in the same order as they appear in the format of *table-name* and will precede any expressions defined as index keys.

ADD KEYS ONLY

Specifies that only the columns specified as index key columns will be added to the format for the index. Other columns from *table-name* will not be added.

ADD *column-name*

Specifies that the listed columns will be added to the format for the index. The index key columns will be first, followed by the added columns.

RENAME

Specifies the columns from *table-name* that will be included in the format for the index. The order of the columns in the index format will be the same as the order of the columns in the list. The columns in the index can also be renamed.

table-system-column-name

Identifies the system column name of a column in *table-name*.

index-system-column-name

Provides the system column name for the corresponding column in the index.

index-column-name

Provides the column name for the corresponding column in the index.

When this clause is used, the following rules apply:

- Each *key-expression* must contain only a *column-name*. It can be either the column name or the system column name of a column in *table-name*. The *key-expression* cannot include an AS clause to rename the column.
- If a list of *table-system-column-names* is specified, it must contain the same number of names as are provided in the index column name list.
- If a list of *table-system-column-names* is not specified, every *index-system-column-name* must be the system column name for a column in *table-name*.
- Each *index-column-name* and *index-system-column-name* must be unique and unqualified.
- Every column in *key-expression* must be included in the RENAME clause.

media-preference

Specifies the preferred storage media for the index.

UNIT ANY

No storage media is preferred. Storage for the index will be allocated from any available storage media.

UNIT SSD

Solid state disk storage media is preferred. Storage for the index may be allocated from solid state disk storage media, if available.

memory-preference

KEEP IN MEMORY

Specifies whether the data for the index should be brought into a main storage pool when the data is used for a query.

NO

The data will not be brought into a main storage pool.

YES

The data will be brought into a main storage pool.

Notes

Effects of the statement: CREATE INDEX creates a description of the index. If the named table already contains data, CREATE INDEX creates the index entries for it. If the table does not yet contain data, the index entries are created when data is inserted into the table.

Collating sequence: Any index created over columns containing SBCS or mixed data is created with the collating sequence in effect at the time the statement is executed. For collating sequences other than *HEX, the key for SBCS data or mixed data is the weighted value of the key based on the collating sequence.

Index attributes: An index is created as a keyed logical file. When an index is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Logical File (CRTLF) command.

The date and time format used for date and time result columns is ISO.

An index created over a distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see [DB2 Multisystem](#).

Index ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the index is created exists, the *owner* of the index is that user profile.
- Otherwise, the *owner* of the index is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the index is the user profile or group user profile of the thread executing the statement.

Index authority: If SQL names are used, indexes are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, indexes are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the index is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the index.

Record format sharing: An index that defines a key column as an expression or that specifies the RCDFMT, WHERE, INCLUDE, or AS clauses does not share the format of *table-name*. Otherwise, the index will share the format of *table-name* and its *format-name* will be the same as the *system-object-name* of the index.

Examples

Example 1: Create an index named UNIQUE_NAM on the PROJECT table. The purpose of the index is to ensure that there are not two entries in the table with the same value for project name (PROJNAME). The index entries are to be in ascending order.

```
CREATE UNIQUE INDEX UNIQUE_NAM  
ON PROJECT(PROJNAME)
```

Example 2: Create an index named JOB_BY_DPT on the EMPLOYEE table. Arrange the index entries in ascending order by job title (JOB) within each department (WORKDEPT).

```
CREATE INDEX JOB_BY_DPT  
ON EMPLOYEE (WORKDEPT, JOB)
```

Example 3: Create an index named DEPT_TYPE on the DEPARTMENT table. Arrange the index entries in ascending order by type of department, which is determined by the second and third characters of the department number (DEPTNO).

```
CREATE INDEX DEPT_TYPE  
ON DEPARTMENT (SUBSTR(DEPTNO,2,2))
```

CREATE MASK

The CREATE MASK statement creates a column mask for column access control at the current server. A column mask specifies what value should be returned for the specified column.

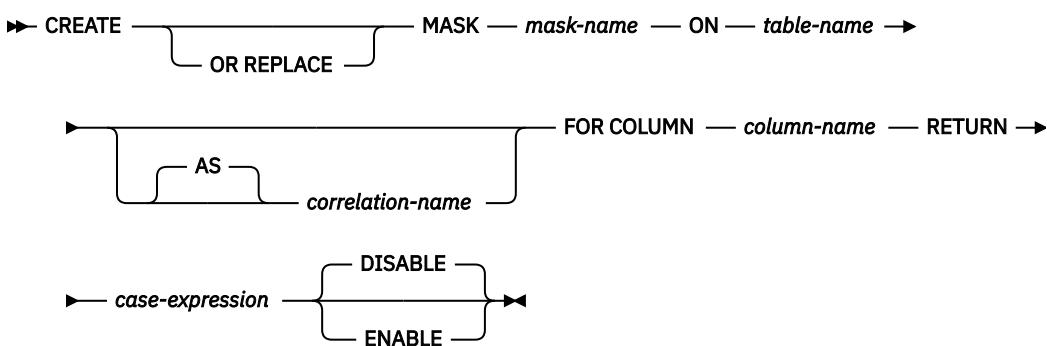

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority. See “[Administrative authority](#)” on page 15.

Syntax

Description

OR REPLACE

Specifies to replace the definition for the column mask if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog.

mask-name

Names the column mask for column access control. The name, including the implicit or explicit qualifier, must not be the same as a column mask or a row permission that already exists at the current server. The *mask-name* cannot start with QIBM.

If SQL names were specified, the mask will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the mask will be created in the schema that is specified by the qualifier. If not qualified and there is no default schema, the mask will be created in the same schema as the *table-name*.

The schema name for the *mask-name* must be the same as the schema name for *table-name*.

table-name

Identifies the table on which the column mask is created. The name must identify a table that exists at the current server. It must not identify a declared temporary table, table in QTEMP, distributed table, view, logical file, member alias, file with read triggers, or catalog table.

correlation-name

Specifies a correlation name that can be used within *case-expression* to designate the table.

FOR COLUMN *column-name*

Identifies the column to which the mask applies. It must be an unqualified name that identifies a column of the table. A mask must not already exist for the column.

RETURN *case-expression*

Specifies a CASE expression to be evaluated to determine the value to return for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, length, null attribute, and CCSID of the CASE expression must be compatible with the data type of the column. If the column does not allow the null value, the result of the CASE expression cannot be the NULL value. For more information about the compatibility of data types see “[Assignments and comparisons](#)” on page 83. If the data type of *column-name* is a user defined data type, the result data type of the CASE expression must be the same user defined type. Any objects referenced in the case expression must exist at the current server. The case expression must not reference any of the following:

- The table for which the column mask is being defined
- A declared global temporary table
- A variable (host variable, SQL variable, SQL parameter, or trigger transition variable)
- A parameter marker
- A user-defined function that is defined as NOT SECURED
- A function that is not deterministic⁹⁷ or has an external action
- An RRN, RID, HASHED_VALUE, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, or DBPARTITIONNUM function that references the table for which the column mask is being defined
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference
- A * or *name.** in a select clause
- A table in QTEMP
- A member alias
- A distributed table
- A file with read triggers
- A multi-format logical file
- A remote object

⁹⁷ STATEMENT DETERMINISTIC functions are allowed but are not recommended.

- A view that contains any of the above

ENABLE or DISABLE

Specifies that the column mask is to be initially enabled or disabled for column access control.

DISABLE

Specifies that the column mask is to be disabled for column access control. The column mask will remain ineffective regardless of whether column access control is activated for the table or not. This is the default.

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for this table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately.

Notes

Prerequisites: In order to create a mask, IBM Advanced Data Security must be installed.

How column masks affect queries: The application of enabled column masks does not interfere with the operations of other clauses within the statement such as WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a sort-key expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on column SSN might change the result of the aggregate function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values. However, if the expression in the query is the same as the expression that is used to mask the column value in the definition of the column mask, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the definition of the column mask. In this particular example, you can remove the expression from the query to avoid the same expression being evaluated twice.

Conflicts between the definition of a column mask and SQL: A column mask is created as a standalone object, without knowing all of the contexts in which it might be used. To mask the value of a column in the final result table, the definition of the column mask is merged into a query by Db2. When the definition of the column mask is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask can return an error. When this happens, either the statement needs to be modified or the column mask must be dropped or recreated with a different definition.

Column masks and null columns: If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the null-padded table in an outer join, the value of the column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, Db2 will add "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 4 shows this added WHEN clause.

Column mask values for SQL data change statements: For INSERT, UPDATE, and MERGE, when a column is referenced while deriving the values of a new row, if that column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert or update and an error is returned. The rules that are used to apply column masks in

order to derive the new values follow the same rules for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability.

Column masks and trigger transition variables: Values for OLD ROW and OLD TABLE transition variables will never contain masked values.

A SET *transition-variable* assignment statement can assign masked data to the variable. If a violation check constraint does not exist for the column, the masked data will be inserted or updated in the table's column and no error will be issued.

Column masks that are created before column access control is activated: The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have only one mask. The definition of a mask is stored in the Db2 catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. A disabled column mask remains ineffective even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE. After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by Db2 to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

Column masks that are created after column access control is activated: The enabled column masks become effective as soon as they are committed. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by Db2 to the statement. Any disabled column mask remains ineffective even when column access control is activated for the table.

No cascaded effect when column or row access control enforced tables are referenced in column mask definitions: A column mask definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns is ignored when the table for which the column mask is being created is referenced in a data manipulation statement.

Examples

Example 1: After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary, who is a manager, can see only the last four characters of the social security number. Peter who is neither cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
  FOR COLUMN SSN RETURN
    CASE
      WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER, 'PAYROLL') = 1)
        THEN SSN
      WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR') = 1)
        THEN 'XXX-XX-' || SUBSTR(SSN, 8, 4)
      ELSE NULL
    END
  ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SSN FROM EMPLOYEE
  WHERE EMPNO = 123456;
```

Example 2: In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this

particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression getting evaluated twice.

```

CREATE MASK SSN_MASK ON EMPLOYEE
FOR COLUMN SSN RETURN
CASE
    WHEN (1 = 1)
        THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
    ELSE NULL
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT 'XXX-XX-' || SUBSTR(SSN,8,4) FROM EMPLOYEE
WHERE EMPNO = 123456;

```

Example 3: Employee with EMPNO 123456 earns bonus \$8000 and salary \$80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

```

CREATE MASK SALARY_MASK ON EMPLOYEE
FOR COLUMN SALARY RETURN
CASE
    WHEN (BONUS < 10000)
        THEN SALARY
    ELSE NULL
END
ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
FOR COLUMN BONUS RETURN
CASE
    WHEN (BONUS > 5000)
        THEN NULL
    ELSE BONUS
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
WHERE EMPNO = 123456;

```

Example 4: This example shows Db2 adds "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition then merges the column mask definition into the statement.

```

CREATE TABLE EMPLOYEE (EMPID INT,
DEPTID CHAR(8),
SALARY DEC(9,2) NOT NULL,
BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
FOR COLUMN SALARY RETURN
CASE
    WHEN SALARY < 10000
        THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
END
ENABLE;

COMMIT;

```

```

CREATE MASK BONUS_MASK ON EMPLOYEE
  FOR COLUMN BONUS RETURN
    CASE
      WHEN BONUS > 1000
        THEN BONUS
      ELSE NULL
    END
  ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM DEPT
  LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is effectively merged into the above statement,
 * 'WHEN SALARY IS NULL THEN NULL' is added by Db2 as the
 * first WHEN clause, as follows:
 */

SELECT CASE WHEN SALARY IS NULL THEN NULL
            WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))
            ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
          END SALARY
  FROM DEPT
  LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

```

CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server. It determines the rows within a table that are available based on the result of the *search-condition*.

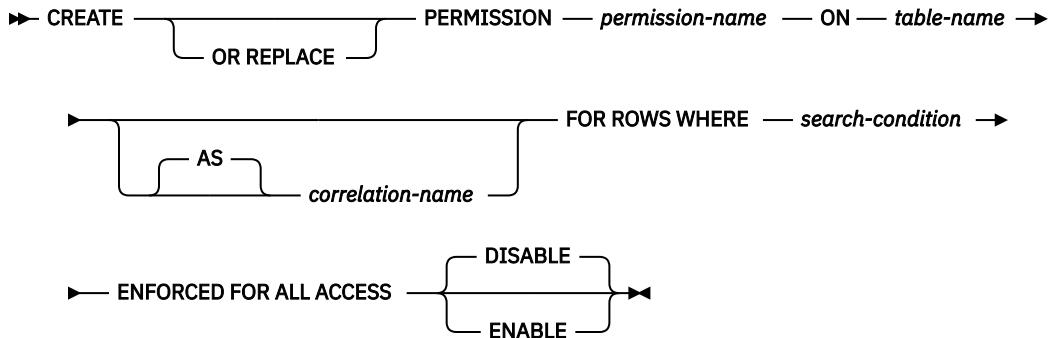

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority. See “[Administrative authority](#)” on page 15.

Syntax

Description

OR REPLACE

Specifies to replace the definition for the row permission if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog.

permission-name

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not be the same as a column mask or a row permission that already exists at the current server. The *permission-name* cannot start with QIBM.

If SQL names were specified, the permission will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the permission will be created in the schema that is specified by the qualifier. If not qualified and there is no default schema, the permission will be created in the same schema as the *table-name*.

The schema name for the *permission-name* must be the same as the schema name for *table-name*.

table-name

Identifies the table on which the column permission is created. The name must identify a table that exists at the current server. It must not identify a declared temporary table, table in QTEMP, distributed table, view, logical file, member alias, file with read triggers, or catalog table.

correlation-name

Specifies a correlation name that can be used within *search-condition* to designate the table.

FOR ROWS WHERE

Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition

Specifies a condition that can be true, false, or unknown for a row of the table.

The *search-condition* follows the same rules used by the search condition in a WHERE clause. In addition, it must not reference any of the following:

- The table for which the row permission is being defined
- A declared global temporary table
- A variable (host variable, SQL variable, SQL parameter, or trigger transition variable)
- A parameter marker
- A user-defined function that is defined as NOT SECURED
- A function that is not deterministic⁹⁸ or has an external action
- An RRN, RID, HASHED_VALUE, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, or DBPARTITIONNUM function that references the table for which the row permission is being defined
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference
- A * or *name.** in a select clause
- A table in QTEMP
- A member alias
- A distributed table
- A file with read triggers
- A multi-format logical file
- A remote object
- A view that contains any of the above

⁹⁸ STATEMENT DETERMINISTIC functions are allowed but are not recommended.

ENFORCED FOR ALL ACCESS

Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, Db2 implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed are insertable or updatable by the user who requested the data change operation.

ENABLE or DISABLE

Specifies that the row permission is to be initially enabled or disabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. The row permission will remain ineffective regardless of whether row access control is activated for the table or not. This is the default.

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for this table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately.

Notes

Prerequisites: In order to create a permission, IBM Advanced Data Security must be installed.

How row permissions are applied and how they affect certain statements: See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

Row permissions that are created before row access control is activated for a table: The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

The definition of the row permission is stored in the Db2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. A row permission can be created as enabled or disabled for row access control. An enabled row permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by Db2 to control access to the table.

Row permissions that are created after row access control is activated for a table: An enabled row permission becomes effective as soon as it is committed. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:

A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables is ignored when the table for which the row permission is being created is referenced in a data manipulation statement.

DECRESULT option for permissions: The DECRESULT option for permissions will always use maximum precision of 63, maximum scale of 63, and minimum divide scale of 0.

Examples

Example 1: Secure user-defined function ACCOUNTING_UDF in row permission SALARY_ROW_ACCESS processes the sensitive data in column SALARY. After row access control is activated for table EMPLOYEE, Accountant Paul retrieves the salary of employee with EMPNO 123456 who is making \$100,000 a year. Paul may or may not see the row depending on the output value from user-defined function ACCOUNTING_UDF.

```
CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE
    FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR', 'ACCOUNTING') = 1
        AND
            ACCOUNTING_UDF(SALARY) < 120000
    ENFORCED FOR ALL ACCESS
    ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
WHERE EMPNO = 123456;
```

Example 2: The tellers in a bank can only access customers from their branch. All tellers have secondary authorization ID TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives have secondary authorization ID CSR. A row permission is created for each group of personnel in the bank according to the access rules defined by someone with security administrator authority. After row access control is activated for table CUSTOMER, in a SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logical OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
    FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'TELLER') = 1
        AND
            BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
                       WHERE EMP_ID = SESSION_USER)
    ENFORCED FOR ALL ACCESS
    ENABLE;

COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
    FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'CSR') = 1
    ENFORCED FOR ALL ACCESS
    ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT * FROM CUSTOMER;
```

CREATE PROCEDURE

The CREATE PROCEDURE statement defines a procedure at the current server.

The following types of procedures can be defined:

- External

The procedure program or service program is written in a programming language such as C, COBOL, or Java. The external executable is referenced by a procedure defined at the current server along with various attributes of the procedure. See “[CREATE PROCEDURE \(external\)](#)” on page 906.

- SQL

The procedure is written exclusively in SQL. The body of an SQL procedure is written in the SQL procedural language, SQL PL. The procedure body is defined at the current server along with various attributes of the procedure. See “[CREATE PROCEDURE \(SQL\)](#)” on page 920.

Notes

Choosing data types for parameters: For portability of procedures across platforms that are not Db2 for i, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying AS LOCATOR for a parameter: Passing a locator instead of a value can result in fewer bytes being passed in or out of the procedure. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters with a LOB or XML data type or a distinct type based on a LOB or XML data type.

AS LOCATOR cannot be specified for SQL procedures.

Determining the uniqueness of procedures in a schema: At the current server, each procedure signature must be unique. The signature of a procedure is the qualified procedure name combined with the number of the parameters (the data types of the parameters are not part of a procedure's signature). This means that two different schemas can each contain a procedure with the same name that have the same number of parameters. However, a schema must not contain two procedures with the same name that have the same number of parameters.

The specific name for a procedure: When defining multiple procedures with the same name and schema (with different number of parameters), it is recommended that a specific name also be specified. The specific name can be used to uniquely identify the procedure when dropping, granting to, revoking from, or commenting on the procedure.

If *specific-name* is not specified, it is the same as the procedure name. If a function or procedure with that specific name already exists, a unique name is generated similar to the rules used to generate unique table names.

Special registers in procedures: The settings of the special registers of the caller are inherited by the procedure when called and restored upon return to the caller. Special registers may be changed within a procedure, but these changes do not affect the caller.

CREATE PROCEDURE (external)

The CREATE PROCEDURE (external) statement defines an external procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
 - The USAGE privilege on the schema that contains the external program or service program.
 - The system authority *EXECUTE on the external program or service program.
- Database administrator authority

If a distinct type or array type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

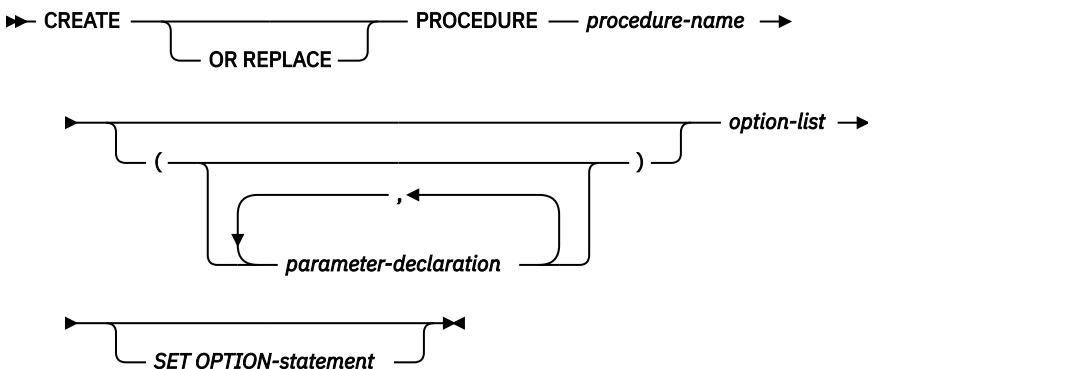

- For each distinct type or array type identified in the statement:
 - The USAGE privilege on the type, and
 - The USAGE privilege on the schema containing the distinct type or array type
- Database administrator authority

To replace an existing procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

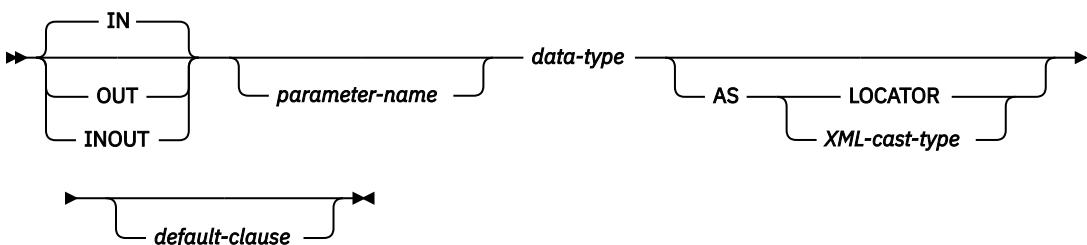

- The following system authorities:
 - The system authority *EXECUTE on the external program or service program
 - All authorities needed to DROP the procedure
 - The system authority *READ to the SYSPROCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

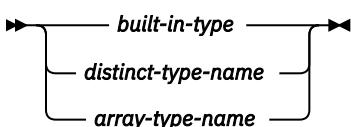

Syntax

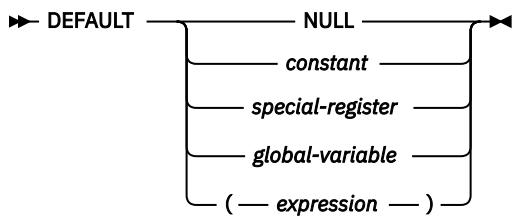

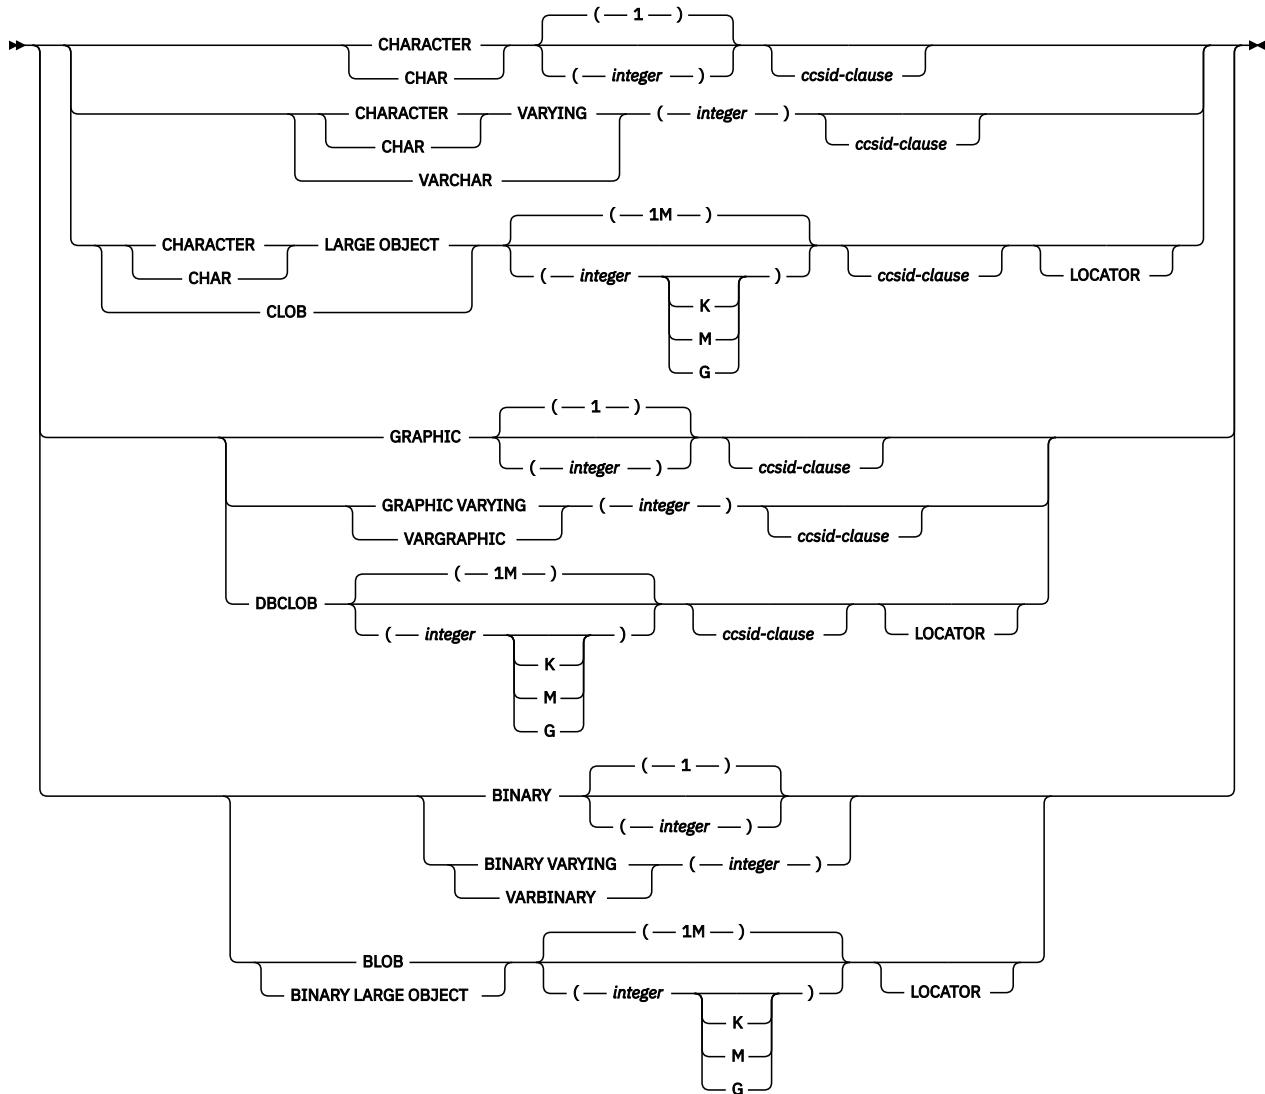

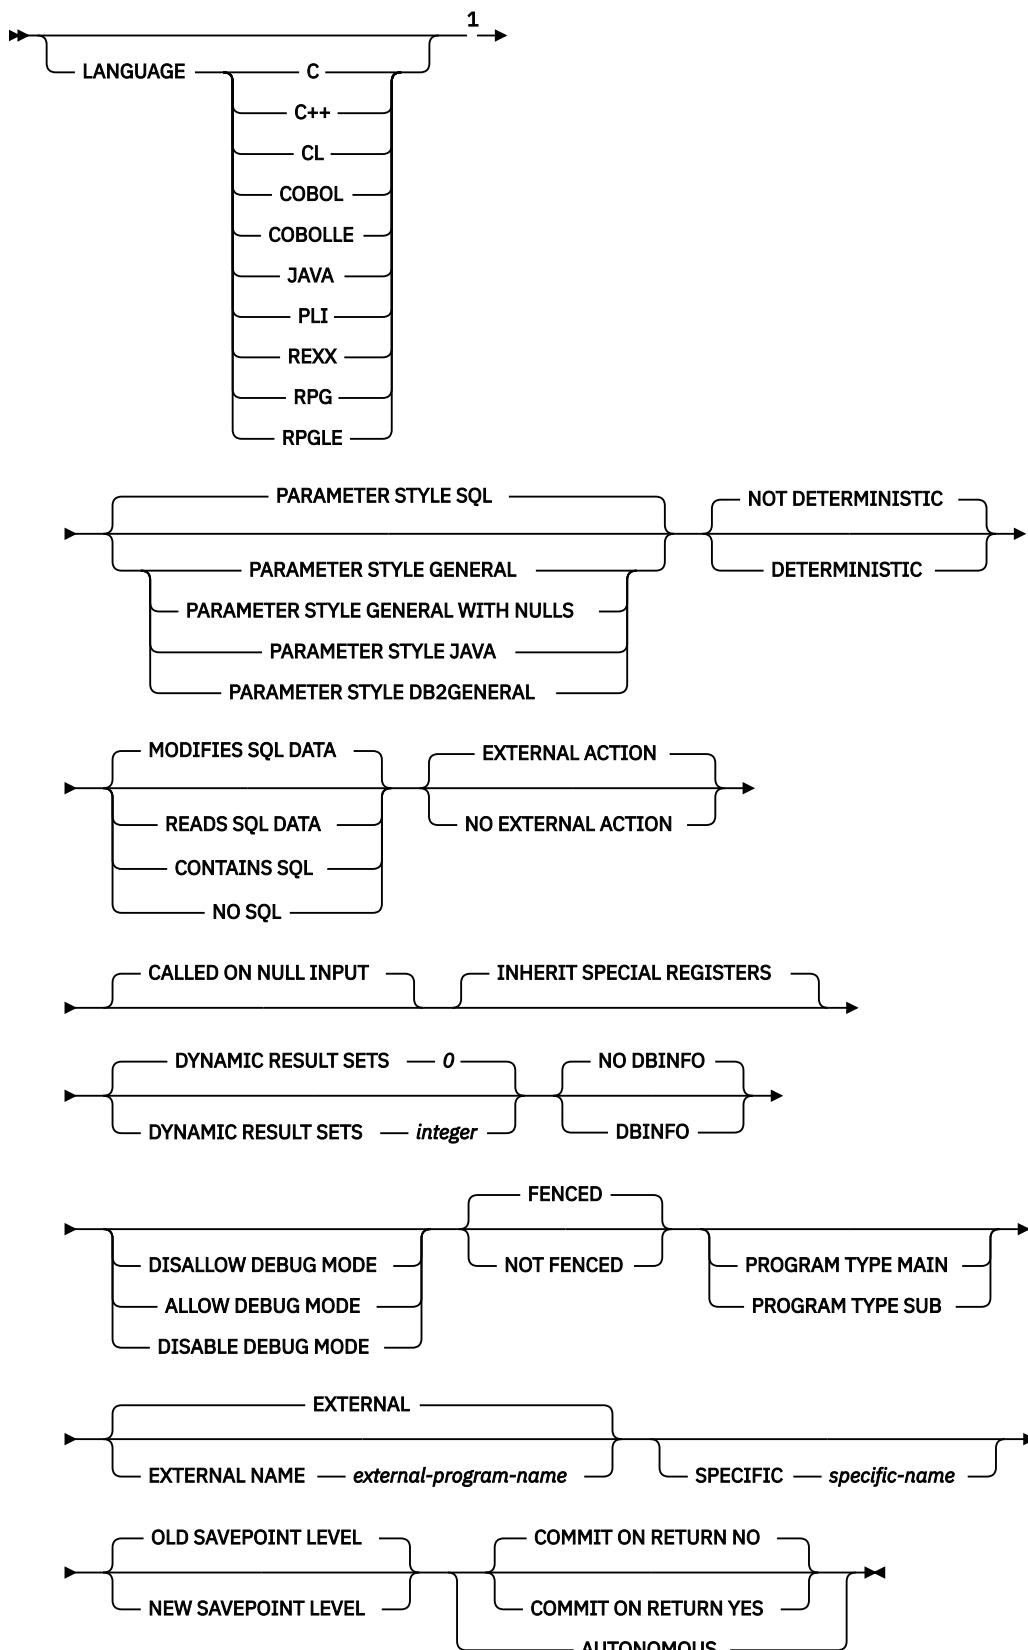

parameter-declaration

data-type

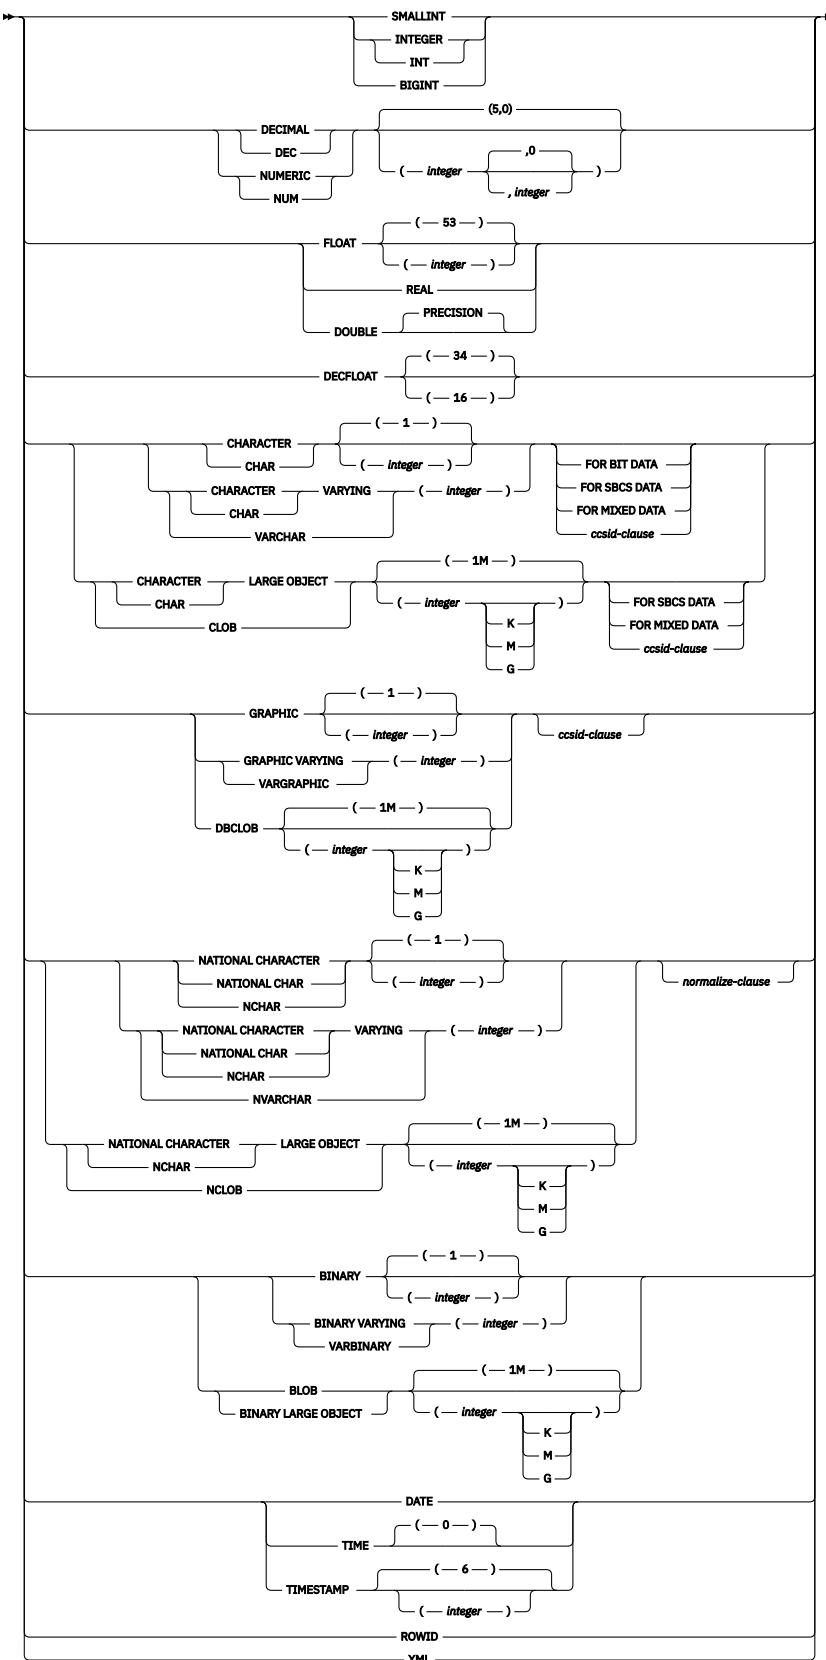

default-clause**XML-cast-type****option-list**

Notes:

¹ The optional clauses can be specified in a different order.

built-in-type

ccsid-clause

►► CCSID — *integer* —
 normalize-clause —►►

normalize-clause**Description****OR REPLACE**

Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the procedure are not affected. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the *specific-name* and *procedure-name* of the new definition must be the same as the *specific-name* and *procedure-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name

Names the procedure. The combination of name, schema name, and the number of parameters must not identify a procedure that exists at the current server unless OR REPLACE is specified.

For SQL naming, the procedure will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the procedure will be created in the schema specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the procedure will be created in the current library (*CURLIB).
- Otherwise, the procedure will be created in the current schema.

(parameter-declaration,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. All parameters are nullable. Although not required, you can give each parameter a name.

The maximum number of parameters allowed in CREATE PROCEDURE depends on the type of language and the parameter style:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs and REXX,
 - If PARAMETER STYLE GENERAL is specified the maximum is 255.
 - If PARAMETER STYLE GENERAL WITH NULLS is specified the maximum is 254.
 - If PARAMETER STYLE SQL is specified the maximum is 254.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

IN

Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned.⁹⁹ The default is IN.

OUT

Identifies the parameter as an output parameter that is returned by the procedure.

A DataLink or a distinct type based on a DataLink cannot be specified as an output parameter.

⁹⁹ When the language type is REXX, all parameters must be input parameters.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If an INOUT parameter is defined with a default and the default is used when calling the procedure, no value for the parameter is returned.

A DataLink or a distinct type based on a DataLink cannot be specified as an input and output parameter.

parameter-name

NAMES the parameter. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see [“CREATE TABLE” on page 945](#).

distinct-type-name

Specifies a distinct type. Any length, precision, scale, or encoding scheme attributes for the parameter are those of the source type of the distinct type as specified using [“CREATE TYPE \(distinct\)” on page 1017](#).

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

array-type-name

Specifies an array type. Array types are only supported for LANGUAGE JAVA. To use an array type as a parameter for a Java stored procedure, the parameter style must be JAVA.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID before passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Some data types are not supported in all languages. For details on the mapping between the SQL data types and host language data types, see [Embedded SQL Programming](#) topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the procedure.

Any parameter that has an XML type must specify either the *XML-cast-type* clause or the AS LOCATOR clause.

AS LOCATOR

Specifies that the parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

AS *XML-cast-type*

Specifies the data type passed to the procedure for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the procedure is created according to the SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See [“XML Values” on page 75](#) for a description of this option.

default

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation of the procedure. The maximum length of the expression string is 64K.

The default expression must not modify SQL data. The expression must be assignment compatible to the parameter data type. All objects referenced in a default expression must exist when the procedure is created. When the procedure is called, the default will be evaluated using the authority of the invoker.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified:

- for an OUT parameter.
- for a parameter of type array.

LANGUAGE

Specifies the language that the external program or service program is written in. The language clause is required if the external program is a REXX procedure.

If LANGUAGE is not specified, the LANGUAGE is determined from the attribute information associated with the external program or service program at the time the procedure is created. If the attribute information associated with the program or service program does not identify a recognizable language or the program or service program cannot be found, then the language is assumed to be C.

C

The external program is written in C.

C++

The external program is written in C++.

CL

The external program is written in CL or ILE CL.

COBOL

The external program is written in COBOL.

COBOLLE

The external program is written in ILE COBOL.

JAVA

The external program is written in JAVA.

PLI

The external program is written in PL/I.

REXX

The external program is a REXX procedure.

RPG

The external program is written in RPG.

RPGLE

The external program is written in ILE RPG.

PARAMETER STYLE

Specifies the conventions used to pass parameters to and returning the values from procedures:

SQL

Specifies that in addition to the parameters on the CALL statement, several additional parameters are passed to the procedure. The parameters are defined to be in the following order:

- The first n parameters are the parameters that are specified on the CREATE PROCEDURE statement.

- n parameters for indicator variables for the parameters.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the procedure. The SQLSTATE returned is assigned by the external program.

The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the procedure.

- A VARCHAR(517) input parameter for the fully qualified procedure name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.

The following additional parameter may be passed as the last parameter:

- A parameter for the dbinfo structure, if DBINFO was specified on the CREATE PROCEDURE statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqlduf in the appropriate source file in library QSYSINC. For example, for C, sqlduf can be found in QSYSINC/H.

PARAMETER STYLE SQL cannot be used with LANGUAGE JAVA.

DB2GENERAL

Specifies that the procedure will use a parameter passing convention that is defined for use with Java methods.

PARAMETER STYLE DB2GENERAL can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#).

GENERAL

Specifies that the procedure will use a parameter passing mechanism where the procedure receives the parameters specified on the CALL. Additional arguments are not passed for indicator variables.

PARAMETER STYLE GENERAL cannot be used with LANGUAGE JAVA.

GENERAL WITH NULLS

Specifies that in addition to the parameters on the CALL statement as specified in GENERAL, another argument is passed to the procedure. This additional argument contains an indicator array with an element for each of the parameters of the CALL statement. In C, this would be an array of short INTs. For more information about how the indicators are handled, see the [SQL Programming](#) topic collection.

PARAMETER STYLE GENERAL WITH NULLS cannot be used with LANGUAGE JAVA.

JAVA

Specifies that the procedure will use a parameter passing convention that conforms to the Java language and ISO/IEC FCD 9075-13:2003, *Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)* specification. INOUT and OUT parameters will be passed as single entry arrays to facilitate returning values.

PARAMETER STYLE JAVA can only be specified with LANGUAGE JAVA. For increased portability, you should write Java procedures that use the PARAMETER STYLE JAVA conventions. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#) topic collection.

Note that the language of the external procedure determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the [SQL Programming](#) topic collection. For Java routines, see the [IBM Developer Kit for Java](#) topic collection.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DETERMINISTIC

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies the classification of SQL statements and nested routines that this procedure can execute. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the procedure, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see Appendix B, “Characteristics of SQL statements,” on page 1421. The default is MODIFIES SQL DATA. This option is ignored for parameter default expressions.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that the procedure can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL.

CONTAINS SQL

Specifies that the procedure can only execute statements with a data access classification of CONTAINS SQL or NO SQL.

NO SQL

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the procedure takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the procedure can take an action that changes the state of an object that the database manager does not manage. EXTERNAL ACTION should be specified if the procedure contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The procedure does not perform an external action.

CALLED ON NULL INPUT

Specifies that the procedure is to be called if any or all argument values are null. This specification means that the procedure must be coded to test for null argument values.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the procedure.

FENCED or NOT FENCED

This parameter is allowed for compatibility with other products and is not used by Db2 for i.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of result sets that can be returned from the procedure. The minimum value for *integer* is zero and the maximum value is 32767.

If no DYNAMIC RESULT SETS clause is specified, result sets are returned for all cursors that remain open when the procedure ends.

Result sets are returned in the order in which the corresponding cursors are opened, unless a SET RESULT SETS statement is executed in the procedure. If the number of cursors that are still open for result sets when the procedure ends exceeds the maximum number specified on the DYNAMIC RESULT SETS clause, a warning is returned on the CALL statement and the number of result sets specified on the DYNAMIC RESULT SETS clause is returned.

If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement. If the SET RESULT SETS statement specifies a number larger than the maximum number of result sets, a warning is returned. Note that any result sets from cursors that have a RETURN TO CLIENT attribute are included in the number of result sets of the outermost procedure.

The result sets are scrollable if a cursor is used to return a result set and the cursor is scrollable. If a cursor is used to return a result set, the result set starts with the current position. Thus, if 5 FETCH NEXT operations have been performed before returning from the procedure, the result set starts with the 6th row of the result set.

Cursor result sets are only returned if the external program does not have an attribute of ACTGRP(*NEW).

For more information about result sets, see [“SET RESULT SETS” on page 1324](#).

DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE

Indicates whether the procedure is created so it can be debugged by the Unified Debugger. If DEBUG MODE is not specified, the procedure will be created with the debug mode specified by the CURRENT DEBUG MODE special register.

DEBUG MODE can only be specified with LANGUAGE JAVA.

DISALLOW DEBUG MODE

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISALLOW, the procedure can be subsequently altered to change the debug mode attribute.

ALLOW DEBUG MODE

The procedure can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is ALLOW, the procedure can be subsequently altered to change the debug mode attribute.

DISABLE DEBUG MODE

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISABLE, the procedure cannot be subsequently altered to change the debug mode attribute.

PROGRAM TYPE

This parameter is allowed for compatibility with other products. It indicates whether the routine's external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

SUB

Specifies that the procedure executes as a procedure in a service program. The external program must be a *SRVPGM object.

MAIN

Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

DBINFO

Specifies whether additional status information is passed to the procedure when it is called. The default is NO DBINFO.

NO DBINFO

Additional information is not passed.

DBINFO

An additional argument is passed when the procedure is called.

The argument is a structure that contains information such as the name of the current server, the application run-time authorization ID, and identification of the version and release of the database manager that called the procedure. See [Table 94 on page 917](#) for further details. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE SQL.

Table 94. DBINFO fields

Field	Data Type	Description
Relational database	VARCHAR(128)	The name of the current server.
Authorization ID	VARCHAR(128)	The run-time authorization ID.
CCSID information	INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER CHAR(8)	<p>The CCSID information of the job. Three sets of three CCSIDs are returned. The following information identifies the three CCSIDs in each set:</p> <ul style="list-style-type: none"> • SBCS CCSID • DBCS CCSID • Mixed CCSID <p>Following the three sets of CCSIDs is an integer that indicates which set of three sets of CCSIDs is applicable and 8 bytes of reserved space.</p> <p>Each set of CCSIDs is for a different encoding scheme (EBCDIC, ASCII, and Unicode).</p> <p>If a CCSID is not explicitly specified for a parameter on the CREATE PROCEDURE statement, the input string is assumed to be encoded in the CCSID of the job at the time the procedure is executed. If the CCSID of the input string is not the same as the CCSID of the parameter, the input string passed to the external procedure will be converted before calling the external program.</p>
Target column	VARCHAR(128) VARCHAR(128) VARCHAR(128)	Not applicable for a call to a procedure.
Version and release	CHAR(8)	The version, release, and modification level of the database manager.
Platform	INTEGER	The server's platform type.

EXTERNAL

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure based on code written in an external programming language.

If NAME clause is not specified, "NAME *procedure-name*" is assumed. In this case, *procedure-name* must not be longer than 8 characters. The NAME clause is required for a LANGUAGE JAVA procedure since the default name is not valid for a Java procedure.

NAME *external-program-name*

Specifies the program or service program that will be executed when the procedure is called by the CALL statement. The program name must identify a program or service program that exists at the application server at the time the procedure is called. If the naming option is *SYS and the name is not qualified:

- The current path will be used to search for the program at the time the procedure is called.
- *LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the procedure.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The external program or service program need not exist at the time the procedure is created, but it must exist at the time the procedure is called.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, and SET TRANSACTION statements are not allowed in a procedure that is running on a remote application server. COMMIT and ROLLBACK statements are not allowed in an ATOMIC SQL procedure or in a procedure that is running on a connection to a remote application server.

SPECIFIC *specific-name*

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a procedure in “[CREATE PROCEDURE](#)” on page 905.

OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL

Specifies whether a new savepoint level is to be created on entry to the procedure.

OLD SAVEPOINT LEVEL

A new savepoint level is not created. Any SAVEPOINT statements issued within the procedure with OLD SAVEPOINT LEVEL implicitly or explicitly specified on the SAVEPOINT statement are created at the same savepoint level as the caller of the procedure. This is the default.

NEW SAVEPOINT LEVEL

A new savepoint level is created on entry to the procedure. Any savepoints set within the procedure are created at a savepoint level that is nested deeper than the level at which this procedure was invoked. Therefore, the name of any new savepoint set within the procedure will not conflict with any existing savepoints set in higher savepoint levels (such as the savepoint level of the calling program or service program) with the same name.

COMMIT ON RETURN

Specifies whether the database manager commits the transaction immediately on return from the procedure.

NO

The database manager does not issue a commit when the procedure returns. NO is the default.

YES

The database manager issues a commit if the procedure returns successfully. If the procedure returns with an error, a commit is not issued.

The commit operation includes the work that is performed by the calling application process and the procedure.¹⁰⁰

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

AUTONOMOUS

Specifies that the procedure is executed in a unit of work that is independent from the calling application. When this option is specified the database always commits or rolls back the autonomous procedure's transactional work based on the SQLSTATE that is returned from the procedure. A SQLSTATE indication of unqualified success or warning will cause the transaction to be committed. All other SQLSTATEs will cause the autonomous procedure's unit of work to be rolled back.

The invocation of any trigger, function, or procedure from within the autonomous procedure will be part of the autonomous procedure's unit of work unless the trigger, function, or procedure was explicitly created to run under a different activation group.

An autonomous procedure cannot be called directly or indirectly from another autonomous procedure.

If AUTONOMOUS is specified, DYNAMIC RESULT SETS 0 must be specified.

¹⁰⁰ If the external program or service program was created with ACTGRP(*NEW) and the job commitment definition is not used, the work that is performed in the procedure will be committed or rolled back as a result of the activation group ending.

SET OPTION-statement

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see “[SET OPTION](#)” on page [1303](#).

The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRL, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE PROCEDURE statement. Other options are accepted but will be ignored.

Notes

General considerations for defining procedures: See “[CREATE PROCEDURE](#)” on page [905](#) for general information about defining procedures.

Language considerations: For information needed to create the programs for a procedure, see [Embedded SQL Programming](#).

REPLACE rules: When an external procedure is recreated by REPLACE:

- Any existing comment or label is discarded.
- If a different external program is specified:
 - Authorized users are not copied to the new program.
 - Journal auditing is not changed.
- Otherwise:
 - Authorized users are maintained. The object owner will not change.
 - Current journal auditing is not changed.

Error handling considerations: Values of arguments passed to a procedure which correspond to OUT parameters are undefined and those which correspond to INOUT parameters are unchanged when an error is returned by the procedure.

Creating the procedure: When an external procedure associated with an ILE external program or service program is created, an attempt is made to save the procedure's attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external procedures subject to the following restrictions:

- The external program library must not be QSYS.
- The external program must exist when the CREATE PROCEDURE statement is issued.

If system naming is specified and the external program name is not qualified, the external program must be found in the library list.

- The external program must be an ILE *PGM or *SRVPGM object.

If the object cannot be updated, the procedure will still be created.

If the external procedure is created in QTEMP, the catalog information is not removed when the job ends.

Calling the procedure: If a DECLARE PROCEDURE statement defines a procedure with the same name as a created procedure, and a static CALL statement where the procedure name is not identified by a variable is executed from the same source program, the attributes from the DECLARE PROCEDURE statement will be used rather than the attributes from the CREATE PROCEDURE statement.

The CREATE PROCEDURE statement applies to static and dynamic CALL statements as well as to a CALL statement where the procedure name is identified by a variable.

When an external procedure is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the procedure runs in the same activation group as the calling program.

The external program or service program for a procedure with the AUTONOMOUS attribute must be defined to run in activation group QSQAUTOAG. When an autonomous procedure is invoked in a job, every procedure that runs in the QSQAUTOAG activation group must have been created with the same storage model. They must all be *TERASPACE or all be *SNGLVL.

Setting of the default value: Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

Notes for Java procedures: To be able to run Java procedures, you must have the [IBM Developer Kit for Java](#) installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java procedure, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the procedure was run.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
- DYNAMIC RESULT SET, RESULT SETS, and RESULT SET may be used as synonyms for DYNAMIC RESULT SETS.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords PARAMETER STYLE DB2SQL can be used as a synonym for PARAMETER STYLE SQL.

Example

Example 1: Create the procedure definition for a procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that are currently available.

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,
                                OUT COST DECIMAL(7,2),
                                OUT QUANTITY INTEGER)
LANGUAGE JAVA
PARAMETER STYLE JAVA
EXTERNAL NAME 'parts.onhand'
```

Example 2: Create the procedure definition for a procedure, written in C, that is passed an assembly number and returns the number of parts that make up the assembly, total part cost and a result set that lists the part numbers, quantity and unit cost of each part.

```
CREATE PROCEDURE ASSEMBLY_PARTS (IN ASSEMBLY_NUM INTEGER,
                                  OUT NUM_PARTS INTEGER,
                                  OUT COST DOUBLE)
LANGUAGE C
PARAMETER STYLE GENERAL
DYNAMIC RESULT SETS 1
FENCED
EXTERNAL NAME ASSEMBLY
```

CREATE PROCEDURE (SQL)

The CREATE PROCEDURE (SQL) statement creates an SQL procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS catalog view and SYSPARMS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE on the Create Program (CRTPGM) command, and
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the procedure is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type or array type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

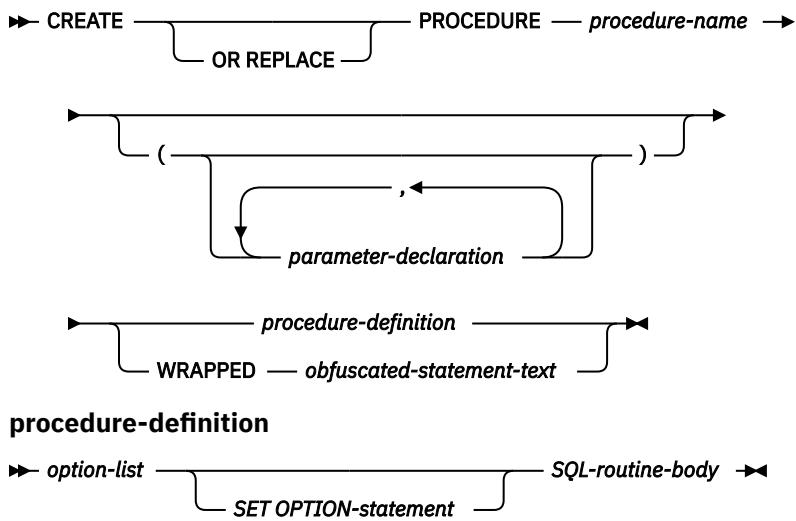

- For each distinct type or array type identified in the statement:
 - The USAGE privilege on the type, and
 - The USAGE privilege on the schema containing the distinct type or array type
- Database administrator authority

To replace an existing procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

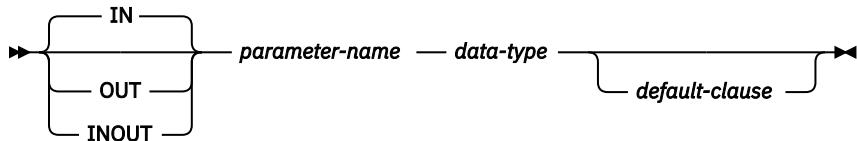

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the program or service program object associated with the procedure
 - All authorities needed to DROP the procedure
 - The system authority *READ to the SYSPROCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

normalize-clause

Description

OR REPLACE

Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the procedure are not affected. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the *specific-name* and *procedure-name* of the new definition must be the same as the *specific-name* and *procedure-name* of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name

Names the procedure. The combination of name, schema name, and the number of parameters must not identify a procedure that exists at the current server unless OR REPLACE is specified.

For SQL naming, the procedure will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the procedure will be created in the schema specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the procedure will be created in the current library (*CURLIB).
- Otherwise, the procedure will be created in the current schema.

The *schema-name* cannot be QSYS2, QSYS, QTTEMP, or SYSIBM.

(*parameter-declaration*,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. All parameters are nullable.

The maximum number of parameters allowed in an SQL procedure is 2000.

IN

Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned. The default is IN.

A parameter that is an array of XML or LOB type is read only.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned. If an INOUT parameter is defined with a default and the default is used when calling the procedure, no value for the parameter is returned.

parameter-name

Names the parameter. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter. The data type can be a built-in data type or a distinct data type.

built-in-type

Specifies a built-in data type. For a more complete description of each built-in data type, see “[CREATE TABLE](#)” on page 945.

distinct-type-name

Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information on creating a distinct type, see “[CREATE TYPE \(distinct\)](#)” on page 1017.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

array-type-name

Specifies an array type.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is called.

default

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation of the procedure. The maximum length of the expression string is 64K.

The default expression must not modify SQL data. The expression must be assignment compatible to the parameter data type. All objects referenced in a default expression must exist when the procedure is created.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified:

- for an OUT parameter.
- for a parameter of type array.

LANGUAGE SQL

Specifies that this procedure is written exclusively in SQL.

SPECIFIC *specific-name*

Specifies a unique name for the procedure. For more information on specific names, see Specifying a specific name for a procedure in “[CREATE PROCEDURE](#)” on page 905.

PROGRAM NAME *external-program-name*

Specifies the unqualified name of the program or service program to be created for the procedure. *external-program-name* must be a valid system name.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC

The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DETERMINISTIC

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements and nested routines that this procedure can execute. The database manager verifies that the SQL statements issued by the procedure, and all routines

locally invoked by the procedure, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1421](#). The default is MODIFIES SQL DATA. This option applies to any parameter default expressions.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that the procedure can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL.

CONTAINS SQL

Specifies that the procedure can only execute statements with a data access classification of CONTAINS SQL or NO SQL.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the procedure takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the procedure can take an action that changes the state of an object that the database manager does not manage. EXTERNAL ACTION should be specified if the procedure contains a reference to another routine that has an external action.

NO EXTERNAL ACTION

The procedure does not perform an external action.

CALLED ON NULL INPUT

Specifies that the procedure is to be called if any or all argument values are null. This specification means that the procedure must be coded to test for null argument values.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the procedure.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of result sets that can be returned from the procedure. The minimum value for *integer* is zero and the maximum value is 32767. The default is DYNAMIC RESULT SETS 0.

Result sets are returned in the order in which the corresponding cursors are opened, unless a SET RESULT SETS statement is executed in the procedure. If the number of cursors still open for result sets when the procedure ends exceeds the maximum number specified on the DYNAMIC RESULT SETS clause, a warning is returned on the CALL statement and the number of result sets specified on the DYNAMIC RESULT SETS clause is returned.

If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement. If the SET RESULT SETS statement specifies a number larger than the maximum number of result sets, a warning is returned. Note that any result sets from cursors that have a RETURN TO CLIENT attribute are included in the number of result sets of the outermost procedure.

The result sets are scrollable if the cursor is used to return a result set and the cursor is scrollable. If a cursor is used to return a result set, the result set starts with the current position. Thus, if 5 FETCH NEXT operations have been performed prior to returning from the procedure, the result set will start with the 6th row of the result set.

For more information about result sets, see [“SET RESULT SETS” on page 1324](#).

DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE

Indicates whether the procedure is created so it can be debugged by the Unified Debugger. If DEBUG MODE is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

DISALLOW DEBUG MODE

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISALLOW, the procedure can be subsequently altered to change the debug mode attribute.

ALLOW DEBUG MODE

The procedure can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is ALLOW, the procedure can be subsequently altered to change the debug mode attribute.

DISABLE DEBUG MODE

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISABLE, the procedure cannot be subsequently altered to change the debug mode attribute.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the procedure cannot be debugged by the Unified Debugger, but may be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

FENCED or NOT FENCED

This parameter is allowed for compatibility with other products and is not used by Db2 for i.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB

Specifies whether the procedure is created as a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN

Specifies that the procedure is created as a program (*PGM).

PROGRAM TYPE SUB

Specifies that the procedure is created as a procedure in a service program (*SRVPGM).

PROGRAM TYPE SUB procedures usually perform slightly better than PROGRAM TYPE MAIN procedures.

OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL

Specifies whether a new savepoint level is to be created on entry to the procedure.

OLD SAVEPOINT LEVEL

A new savepoint level is not created. Any SAVEPOINT statements issued within the procedure with OLD SAVEPOINT LEVEL implicitly or explicitly specified on the SAVEPOINT statement are created at the same savepoint level as the caller of the procedure. This is the default.

NEW SAVEPOINT LEVEL

A new savepoint level is created on entry to the procedure. Any savepoints set within the procedure are created at a savepoint level that is nested deeper than the level at which this procedure was invoked. Therefore, the name of any new savepoint set within the procedure will not conflict with any existing savepoints set in higher savepoint levels (such as the savepoint level of the calling program) with the same name.

COMMIT ON RETURN

Specifies whether the database manager commits the transaction immediately on return from the procedure.

NO

The database manager does not issue a commit when the procedure returns. NO is the default.

YES

The database manager issues a commit if the procedure returns successfully. If the procedure returns with an error, a commit is not issued.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

AUTONOMOUS

Specifies that the procedure is executed in a unit of work that is independent from the calling application. When this option is specified the database always commits or rolls back the autonomous procedure's transactional work based on the SQLSTATE that is returned from the procedure. A SQLSTATE indication of unqualified success or warning will cause the transaction to be committed. All other SQLSTATEs will cause the autonomous procedure's unit of work to be rolled back.

The invocation of any trigger, function, or procedure from within the autonomous procedure will be part of the autonomous procedure's unit of work unless the trigger, function, or procedure was explicitly created to run under a different activation group.

An autonomous procedure cannot be called directly or indirectly from another autonomous procedure.

If AUTONOMOUS is specified, DYNAMIC RESULT SETS 0 must be specified.

CONCURRENT ACCESS RESOLUTION

Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

DEFAULT

Specifies that the concurrent access resolution is not explicitly set for this procedure. The value that is in effect when the procedure is called will be used.

WAIT FOR OUTCOME

Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SYSTEM_TIME SENSITIVE

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

YES

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NO

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the procedure. A CREATE PROCEDURE statement can be encoded using the WRAP scalar function.

SET OPTION-*statement*

Specifies the options that will be used to create the procedure. These options also apply to any default value expressions. For example, to create a debuggable procedure, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1303](#).

The options CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE PROCEDURE statement. CLOSQLCSR(*ENDMOD) is the default for SQL scalar functions. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRL, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single *SQL-procedure-statement*, including a compound statement. See “[SQL control statements](#)” on page 1359 for more information about defining SQL procedures.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, and SET TRANSACTION statements are not allowed in a procedure that is running on a remote application server. COMMIT and ROLLBACK statements are not allowed in an ATOMIC SQL procedure or in a procedure that is running on a connection to a remote application server.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL Table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining procedures: See “[CREATE PROCEDURE](#)” on page 905 for general information on defining procedures.

Procedure ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the procedure is created exists, the *owner* of the procedure is that user profile.
- Otherwise, the *owner* of the procedure is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the procedure is the user profile or group user profile of the thread executing the statement.

Procedure authority: If SQL names are used, procedures are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, procedures are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the procedure is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the procedure.

REPLACE rules: When a procedure is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

Error handling in procedures: Consideration should be given to possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement results in the exception SQLSTATE being returned to the caller of the procedure. Values of arguments passed to a procedure that correspond to OUT parameters are undefined and those that correspond to INOUT parameters are unchanged when an error is returned by the procedure.

Creating the procedure: When an SQL procedure is created, SQL creates a temporary source file that will contain C source code with embedded SQL statements. A program or service program object is then created using the CRTPGM or CRTSRVPGM command. The SQL options used to create the program are the options that are in effect at the time the CREATE PROCEDURE statement is executed. If AUTONOMOUS is specified, the program or service program is created with ACTGRP(QSQAUTOAG). Otherwise, the program is created with ACTGRP(*CALLER).

When an SQL procedure is created, the procedure's attributes are stored in the created program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

If the PROGRAM NAME clause is provided, its name is used for the creation of the program object. Otherwise, the specific procedure name is used as the name of the member in the source file and the name of the program object, if it is a valid system name. If the procedure name is not a valid system name, a unique name is generated. If a source file member with the same name already exists, the member is overlaid. If a module or a program with the same name already exists, the objects are not

overlaid, and a unique name is generated. The unique names are generated according to the rules for generating system table names.

Invoking the procedure: If a DECLARE PROCEDURE statement defines a procedure with the same name as a created procedure, and a static CALL statement where the procedure name is not identified by a variable is executed from the same source program, the attributes from the DECLARE PROCEDURE statement will be used rather than the attributes from the CREATE PROCEDURE statement.

The CREATE PROCEDURE statement applies to static and dynamic CALL statements as well as to a CALL statement where the procedure name is identified by a variable.

SQL procedures must be called using the SQL CALL statement. When called, the SQL procedure runs in the activation group of the calling program.

SQL procedures are built with the *TERASPACE storage model. When an autonomous SQL procedure is invoked in a job, every procedure that runs in the QSQAUTOAG activation group must use the *TERASPACE storage model.

Obfuscated statements: A CREATE PROCEDURE statement can be executed in obfuscated form. In an obfuscated statement, only the procedure name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the procedure is created from an obfuscated statement are ignored. A procedure that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Setting of the default value: Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

Dependent objects: An SQL routine is dependent on objects that are referenced in the *SQL-routine-body*. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference in the *SQL-routine-body* is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- DYNAMIC RESULT SET, RESULT SETS, and RESULT SET may be used as synonyms for DYNAMIC RESULT SETS.

Example

Create an SQL procedure that returns the median staff salary. Return a result set containing the name, position, and salary of all employees who earn more than the median salary.

```
CREATE PROCEDURE MEDIAN_RESULT_SET (OUT medianSalary DECIMAL(7,2))
LANGUAGE SQL
DYNAMIC RESULT SETS 1
BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE c1 CURSOR FOR
        SELECT salary
        FROM staff
        ORDER BY salary;
    DECLARE c2 CURSOR WITH RETURN FOR
        SELECT name, job, salary;
```

```

        FROM staff
        WHERE salary > medianSalary
        ORDER BY salary;
DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;
    SET medianSalary = 0;
    SELECT COUNT(*) INTO v_numRecords FROM STAFF;
    OPEN c1;
    WHILE v_counter < (v_numRecords / 2 + 1)
        DO FETCH c1 INTO medianSalary;
        SET v_counter = v_counter + 1;
    END WHILE;
    CLOSE c1;
    OPEN c2;
END

```

CREATE SCHEMA

The CREATE SCHEMA statement defines a schema at the current server and optionally creates tables, views, aliases, indexes, sequences, and distinct types. Comments and labels may be added in the catalog description of these objects, and privileges can be granted to users.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The *USE system authority to the following CL commands:
 - Create Library (CRTLIB)
 - If WITH DATA DICTIONARY is specified, Create Data Dictionary (CRTDTADCT)
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

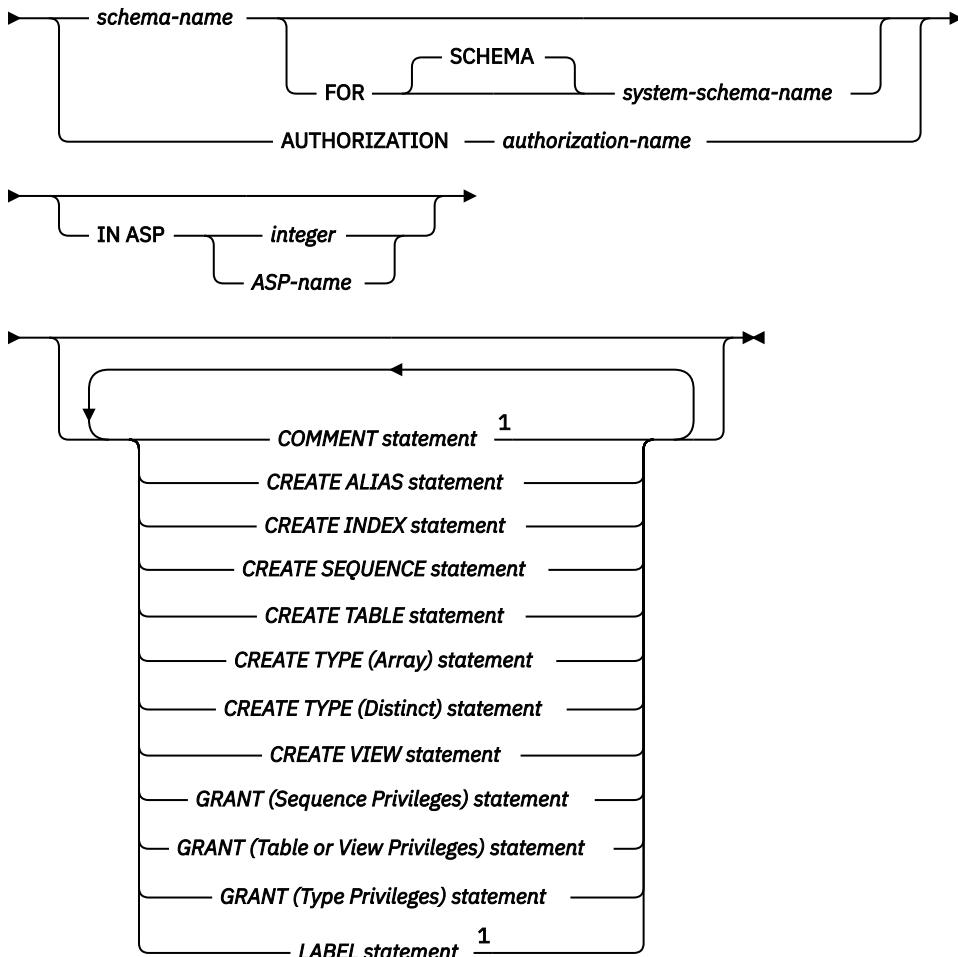

- The privileges defined for each SQL statement included in the CREATE SCHEMA statement
- Database administrator authority

If the AUTHORIZATION clause is specified, the privileges held by the authorization ID of the statement must also include at least one of the following:

- The system authority *ADD to the user profile identified by authorization-name
- Database administrator authority

Syntax

► CREATE SCHEMA →

Notes:

¹ Only labels and comments on object types created in the schema are supported in the CREATE SCHEMA statement.

Description

schema-name

Names the schema. A schema is created using this name. If *schema-name* is specified, the authorization ID of the statement is the run-time authorization ID. The name must not be the same as the name of an existing schema at the current server. The name should not begin with 'SYS' or 'Q'. Such schema names indicate that the schema is a *system schema*.

If the *schema-name* is not a valid system name and a *system-schema-name* is not specified, SQL will generate a system name. For information about the rules for generating the name, see “[Rules for Schema Name Generation](#)” on page 937.

FOR SCHEMA *system-schema-name*

Identifies the system name of the schema. *system-schema-name* must not be the same as a schema that already exists at the current server. The *system-schema-name* must be an unqualified system identifier that is a valid system name.

If both *schema-name* and *system-schema-name* are specified, they cannot both be valid system names.

authorization-name

Identifies the authorization ID of the statement. This authorization name is also the schema-name. The name must not be the same as the name of an existing schema at the current server.

IN ASP

Specifies the auxiliary storage pool (ASP) in which to create the schema.

integer

The integer must be between 1 and 32. If 1 is specified, the schema is created on the system ASP.

ASP-name

The name must identify an auxiliary storage pool that exists at the current server.

If this clause is omitted,

- If the name space of the invoking thread is set to an independent auxiliary storage pool (IASP), the schema will be created in the IASP name space.
- Otherwise, an ASP of 1 is assumed.

COMMENT statement

Adds or replaces comments in the catalog descriptions of an object created in the schema. Only comments on objects created in the schema are allowed. See the COMMENT statement “[COMMENT](#)” on page 780.

CREATE ALIAS statement

Creates an alias into the schema. See the CREATE ALIAS statement “[CREATE ALIAS](#)” on page 809.

CREATE INDEX statement

Creates an index into the schema. See the CREATE INDEX statement “[CREATE INDEX](#)” on page 889.

CREATE SEQUENCE statement

Creates a sequence into the schema. See the CREATE SEQUENCE statement “[CREATE SEQUENCE](#)” on page 938.

CREATE TABLE statement

Creates a table into the schema. See the CREATE TABLE statement “[CREATE TABLE](#)” on page 945.

CREATE TYPE (Array) statement

Creates an array type into the schema. See the CREATE TYPE (Array) statement “[CREATE TYPE \(array\)](#)” on page 1013.

CREATE TYPE (Distinct) statement

Creates a user-defined distinct type into the schema. See the CREATE TYPE (Distinct) statement “[CREATE TYPE \(distinct\)](#)” on page 1017.

CREATE VIEW statement

Creates a view into the schema. See the CREATE VIEW statement “[CREATE VIEW](#)” on page 1029.

GRANT (Sequence Privileges) statement

Grants privileges for sequences in the schema. See the GRANT statement “[GRANT \(sequence privileges\)](#)” on page 1181.

GRANT (Table or View Privileges) statement

Grants privileges for tables and views in the schema. See the GRANT statement “[GRANT \(table or view privileges\)](#)” on page 1183.

GRANT (Type Privileges) statement

Grants privileges for types in the schema. See the GRANT statement “[GRANT \(type privileges\)](#)” on page 1189.

LABEL statement

Adds or replaces labels in the catalog descriptions of an object created in the schema. Only labels on objects created in the schema are allowed. See the LABEL statement “[LABEL](#)” on page 1211.

Notes

Schema attributes: A schema is created as:

- A library: A library groups related objects, and allows you to find objects by name.

- A catalog: A catalog contains descriptions of the tables, views, indexes, and other objects in the schema. A catalog consists of a set of views. For more information, see [SQL Programming](#).
- A journal and journal receiver: A journal QSQJRN and journal receiver QSQJRN0001 is created in the schema, and is used to record changes to all tables subsequently created in the schema. For more information, see [Journal Management](#).

An index created over a distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see [DB2 Multisystem](#).

Object ownership: The owner of the schema and created objects is determined as follows:

- If an AUTHORIZATION clause is specified, the specified authorization ID owns the schema and all objects created by the statement.
- Otherwise, the *owner* of the schema and all objects created by the statement is the user profile or the group user profile of the thread executing the statement.

Object authority: If SQL names are used, the schema and any other objects are created with the system authority of *EXCLUDE on *PUBLIC and the library is created with the create authority parameter CRTAUT(*EXCLUDE). The owner is the only user having any authority to the schema. If other users require authority to the schema, the owner can grant authority to the objects created; using the CL command Grant Object Authority (GRTOBJAUT).

If system names are used, the schema and any other objects are created with the system authority given to *PUBLIC is determined by the system value QCRTAUT, and the library is created with CRTAUT(*SYSVAL). For more information about system security, see [Security Reference](#), and [SQL Programming](#).

If the owner of the schema is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the schema.

Object names: If a CREATE TABLE, CREATE INDEX, CREATE ALIAS, CREATE TYPE, CREATE SEQUENCE, or CREATE VIEW statement contains a qualified name for the table, index, alias, distinct type, sequence, or view being created, the schema name specified in that qualified name must be the same as the name of the schema being created. Any other object names referenced within the schema definition may be qualified by any schema name. Unqualified table, index, alias, distinct type, sequence, or view names in any SQL statement are implicitly qualified with the name of the created schema.

Delimiters are not used between the SQL statements.

SQL statement length: If the CREATE SCHEMA statement is executed via the RUNSQLSTM command, the maximum length of any individual CREATE TABLE, CREATE INDEX, CREATE TYPE, CREATE ALIAS, CREATE SEQUENCE, CREATE VIEW, COMMENT, LABEL, or GRANT statements within the CREATE SCHEMA statement is 2 097 152. Otherwise, the entire CREATE SCHEMA statement is limited to 2 097 152.

Name resolution performance: The name of the schema can affect the performance of statements that reference objects in the schema. If the length of a schema name is greater than 30, the performance of finding objects in the schema will be worse than schemas whose name length is less than or equal to 30. To minimize the performance impact, ensure that the first 5 characters of the system name and the schema name are the same.

Syntax alternatives: The COLLECTION keyword can be used as a synonym for SCHEMA for compatibility to prior releases. This keyword is non-standard and should not be used.

Deprecated features: The WITH DATA DICTIONARY clause causes an IDDU data dictionary to be created in the schema. While the clause can still be specified at the end of the CREATE SCHEMA statement and is still supported; it is not recommended.

A schema created with a data dictionary cannot contain tables with LOB, XML, or DATALINK columns. The clause has no effect on the creation of catalog views.

Rules for Schema Name Generation

A system name will be generated if a schema is created with a name that is longer than 10 characters.

The SQL name or its corresponding system name may both be used in SQL statements to access the schema once it is created. However, the SQL name is only recognized by Db2 for i and the system name must be used in other environments.

If the *schema-name* is an ordinary identifier and longer than 10 characters, a 10-character *system-schema-name* will be generated as:

- The first 5 characters of the name
- A 5 digit unique number

For example:

```
The system-schema-name for LONGSCHEMANAME would be LONGS00001
```

If the *schema-name* is a delimited identifier and longer than 10 characters, a 10-character *system-schema-name* will be generated as:

- The first 4 characters from within the delimiters will be used as the first characters of the *system-schema-name*.
- If the first 4 characters are all uppercase letters, digits, or underscores, an underscore and a 5 digit unique number is appended.
- Otherwise, a 4 digit unique number is appended.

For example:

```
The system name for "longschemaname" would be "long0001"  
The system name for "LONGSchemaName" would be LONG_00001
```

Examples

Example 1: Create a schema that has an inventory part table and an index over the part number. Give authority to the schema to the user profile JONES.

```
CREATE SCHEMA INVENTORY  
  
CREATE TABLE PART (PARTNO SMALLINT NOT NULL,  
                   DESCRIPTOR VARCHAR(24),  
                   QUANTITY INT)  
  
CREATE INDEX PARTIND ON PART (PARTNO)  
  
GRANT ALL ON PART TO JONES
```

Example 2: Create a schema using the authorization ID of SMITH. Create a student table that has a comment on the student number column.

```
CREATE SCHEMA AUTHORIZATION SMITH  
  
CREATE TABLE SMITH.STUDENT (STUDNBR SMALLINT NOT NULL UNIQUE,  
                           LASTNAME CHAR(20),  
                           FIRSTNAME CHAR(20),  
                           ADDRESS CHAR(50))  
  
COMMENT ON STUDENT (STUDNBR IS 'THIS IS A UNIQUE ID#')
```

CREATE SEQUENCE

The CREATE SEQUENCE statement creates a sequence at the application server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Create Data Area (CRTDTAARA) command
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSSEQOBJECTS catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

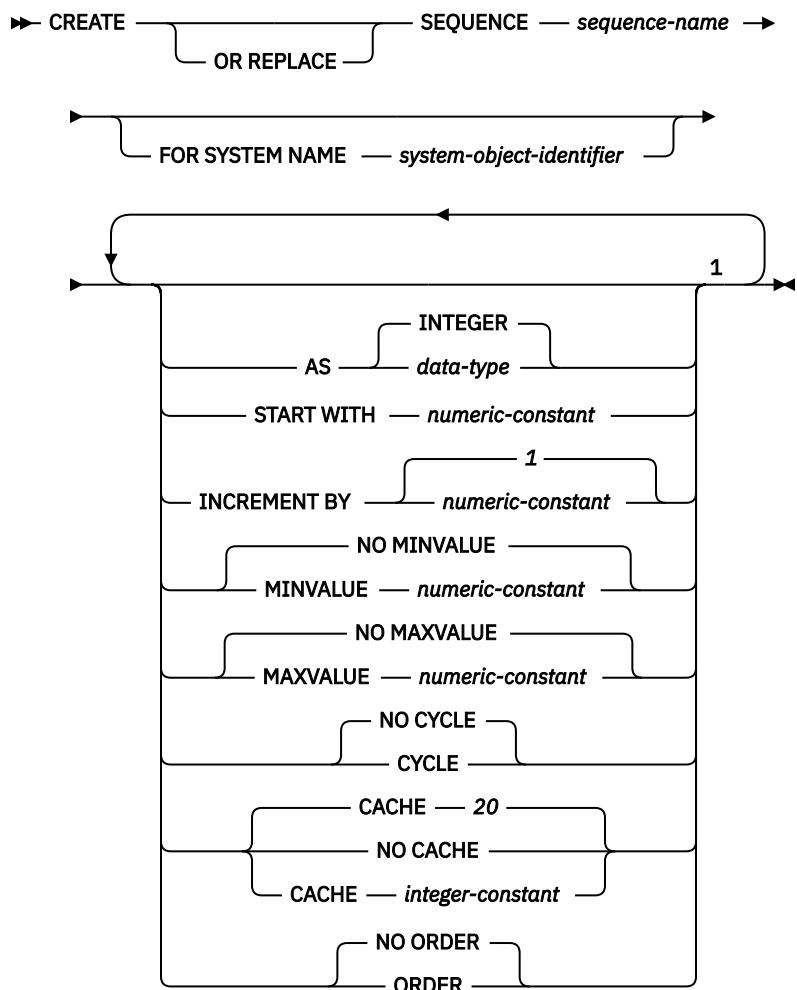

- For the distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

To replace an existing sequence, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the data area associated with the sequence
 - All authorities needed to DROP the sequence
 - The system authority *READ to the SYSSEQOBJECTS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Sequence](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

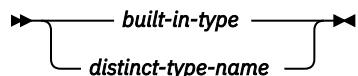

Syntax

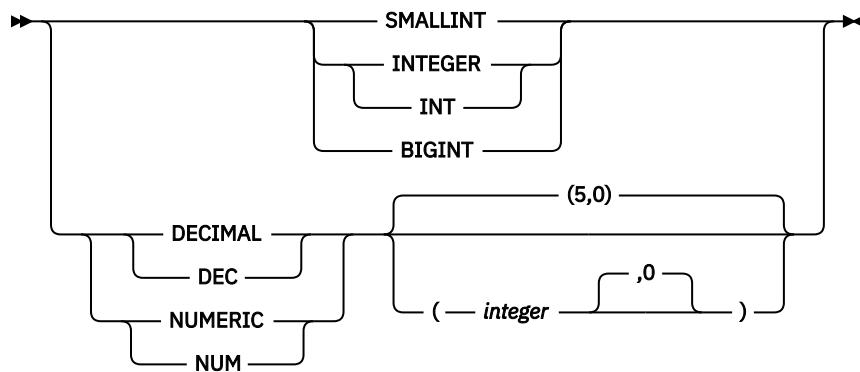

Notes:

¹ The same clause must not be specified more than once.

data-type

built-in-type

Description

OR REPLACE

Specifies to replace the definition for the sequence if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the sequence are not affected. This option is ignored if a definition for the sequence does not exist at the current server.

sequence-name

Names the sequence. The name, including the implicit or explicit qualifier, must not identify a sequence or data area that already exists at the current server. If a qualified sequence name is specified, the *schema-name* cannot be QSYS2, QSYS, or SYSIBM.

If SQL names were specified, the sequence will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the sequence will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the sequence will be created in the current library (*CURLIB).
- Otherwise, the sequence will be created in the current schema.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the sequence. *system-object-identifier* must not be the same as a sequence or data area that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *sequence-name* must not be a valid system object name.

AS *data-type*

Specifies the data type to be used for the sequence value. The data type can be any exact numeric type (SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC) with a scale of zero, or a user-defined distinct type for which the source type is an exact numeric type with a scale of zero. The default is INTEGER.

built-in-type

Specifies the built-in data type used as the basis for the internal representation of the sequence. If the data type is DECIMAL or NUMERIC, the precision must be less than or equal to 63 and the scale must be 0. See [“CREATE TABLE” on page 945](#) for a more complete description of each built-in data type.

For portability of applications across platforms, use DECIMAL instead of a NUMERIC data type.

distinct-type-name

Specifies that the data type of the sequence is a distinct type (a user-defined data type). If the source type is DECIMAL or NUMERIC, the precision of the sequence is the precision of the source type of the distinct type. The precision of the source type must be less than or equal to 63 and the scale must be 0. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

START WITH *numeric-constant*

Specifies the first value that is generated for the sequence. The value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence, without non-zero digits to the right of the decimal point.

If a value is not explicitly specified when the sequence is defined, the default is the MINVALUE for an ascending sequence and the MAXVALUE for a descending sequence.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence, and

does not exceed the value of a large integer constant, without nonzero digits existing to the right of the decimal point.

If the value is 0 or positive, this is an ascending sequence. If the value is negative, this is a descending sequence. The default is 1.

NO MINVALUE or MINVALUE

Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value. The default is NO MINVALUE.

NO MINVALUE

For an ascending sequence, the value is the START WITH value, or 1 if START WITH is not specified. For a descending sequence, the value is the minimum value of the data type (and precision, if DECIMAL or NUMERIC) associated with the sequence.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence and without non-zero digits to the right of the decimal point. The value must be less than or equal to the maximum value.

NO MAXVALUE or MAXVALUE

Specifies the maximum value at which an ascending sequence either cycles or stops generating values, or a descending sequence cycles to after reaching the minimum value. The default is NO MAXVALUE.

NO MAXVALUE

For an ascending sequence, the value is the maximum value of the data type (and precision, if DECIMAL or NUMERIC) associated with the sequence. For a descending sequence, the value is the START WITH value, or -1 if START WITH is not specified.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence and without non-zero digits to the right of the decimal point. The value must be greater than or equal to the minimum value.

NO CYCLE or CYCLE

Specifies whether this sequence should continue to generate values once the maximum or minimum value of the sequence has been reached. The default is NO CYCLE.

NO CYCLE

Specifies that values will not be generated for the sequence once the maximum or minimum value for the sequence has been reached.

CYCLE

Specifies that values continue to be generated for this sequence after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches the maximum value of the sequence, it generates its minimum value. After a descending sequence reaches its minimum value of the sequence, it generates its maximum value. The maximum and minimum values for the column determine the range that is used for cycling.

When CYCLE is in effect, then duplicate values can be generated for the sequence.

CACHE or NO CACHE

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of the NEXT VALUE sequence expression. The default is CACHE 20.

CACHE *integer-constant*

Specifies the maximum number of sequence values that are preallocated and kept in memory. Preallocating and storing values in the cache improves performance.

In certain situations, such as system failure, all cached sequence values that have not been used in committed statements are lost, and thus, will never be used. The value specified for the CACHE option is the maximum number of sequence values that could be lost in these situations.

The minimum value that can be specified is 2.

NO CACHE

Specifies that values for the sequence are not preallocated. If NO CACHE is specified, the performance of the NEXT VALUE sequence expression will be worse than if CACHE is specified.

ORDER or NO ORDER

Specifies whether the sequence values must be generated in order of request. The default is NO ORDER.

NO ORDER

Specifies that the sequence numbers do not need to be generated in order of request.

ORDER

Specifies that the sequence numbers are generated in order of request. If ORDER is specified, the performance of the NEXT VALUE sequence expression will be worse than if NO ORDER is specified.

Notes

Sequence attributes: A sequence is created as a *DTAARA object. The *DTAARA objects should not be changed with the Change Data Area (*CHGDTAARA) or any other similar interface because doing so may cause unexpected failures or unexpected results when attempting to use the SQL sequence through SQL.

Sequence ownership: The *owner* of the sequence is the user profile or group user profile of the thread executing the statement.

Sequence authority: If SQL names are used, sequences are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, sequences are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the sequence is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the sequence.

REPLACE rules: When a sequence is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

Relationship of MINVALUE and MAXVALUE: Typically, MINVALUE will be less than MAXVALUE, but this is not required. MINVALUE could be equal to MAXVALUE. If START WITH was the same value as MINVALUE and MAXVALUE, and CYCLE is implicitly or explicitly specified, this would be a constant sequence. In this case a request for the next value appears to have no effect because all the values generated by the sequence are in fact the same.

MINVALUE must not be greater than MAXVALUE

Defining constant sequences: It is possible to define a sequence that would always return a constant value. This could be done by specifying an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE, or by specifying the same value for START WITH, MINVALUE and MAXVALUE. For a constant sequence, each time a NEXT VALUE expression is processed the same value is returned. A constant sequence can be used as a numeric global variable. ALTER SEQUENCE can be used to adjust the values that will be generated for a constant sequence.

Defining sequences that cycle: A sequence can be cycled manually by using the ALTER SEQUENCE statement. If NO CYCLE is implicitly or explicitly specified, the sequence can be restarted or extended using the ALTER SEQUENCE statement to cause values to continue to be generated once the maximum or minimum value for the sequence has been reached.

A sequence can be explicitly defined to cycle by specifying the CYCLE keyword. Use the CYCLE option when defining a sequence to indicate that the generated values should cycle once the boundary is reached. When a sequence is defined to automatically cycle (for example CYCLE was explicitly specified), then the maximum or minimum value generated for a sequence may not be the actual MAXVALUE or MINVALUE specified, if the increment is a value other than 1 or -1. For example, the sequence defined with START WITH=1, INCREMENT=2, MAXVALUE=10 will generate a maximum value of 9, and will not generate the value 10.

When defining a sequence with CYCLE, then any application conversion tools (for converting applications from other vendor platforms to Db2) should also explicitly specify MINVALUE, MAXVALUE and START WITH.

Caching sequence numbers: A range of sequence numbers can be kept in memory for fast access. When an application accesses a sequence that can allocate the next sequence number from the cache, the sequence number allocation can happen quickly. However, if an application accesses a sequence that cannot allocate the next sequence number from the cache, the sequence number allocation will require an update to the *DTAARA object.

Choosing a high value for CACHE allows faster access to more successive sequence numbers. However, in the event of a failure, all sequence values in the cache are lost. If the NO CACHE option is used, the values of the sequence are not stored in the sequence cache. In this case every access to the sequence requires an update to the *DTAARA object. The choice of the value for CACHE should be made keeping the trade-off between performance and application requirements in mind.

Persistence of the most recently generated sequence value: The database manager remembers the most recently generated value for a sequence within the SQL-session, and returns this value for a PREVIOUS VALUE expression specifying the sequence name. The value persists until either the next value is generated for the sequence, the sequence is dropped, altered, or replaced, or until the end of the application session. The value is unaffected by COMMIT and ROLLBACK statements.

PREVIOUS VALUE is defined to have a linear scope within the application session. Therefore, in a nested application:

- on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, specifying an invocation of a PREVIOUS VALUE expression in a nested application will reflect sequence activity done in the invoking application, routine, or trigger before entering the nested application. An invocation of PREVIOUS VALUE expression in a nested application results in an error if a NEXT VALUE expression for the specified sequence had not yet been done in the invoking application, routine, or trigger.
- on return from a function, procedure, or trigger, the invoking application, routine or trigger will be affected by any sequence activity in the function, procedure, or trigger. That is, an invocation of PREVIOUS VALUE in the invoking application, routine, or trigger after returning from the nested application will reflect any sequence activity that occurred in the lower level applications.

Sequence journaling: When a sequence is created, journaling may be automatically started if the sequence is created into a schema that has specified (using the STRJRNLIB command) that journaling should implicitly be started.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases of other Db2 products. These keywords are non-standard and should not be used:

- The keywords NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be used as synonyms for NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER.
- A comma can be used to separate multiple sequence options.

Examples

Create a sequence called ORG_SEQ that starts at 1, increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORG_SEQ  
START WITH 1
```

```
INCREMENT BY 1
NO MAXVALUE
NO CYCLE
CACHE 24
```

The options START WITH 1, INCREMENT 1, NO MAXVALUE, and NO CYCLE are the values that would have been used if they had not been explicitly specified.

CREATE TABLE

The CREATE TABLE statement defines a table at the current server. The definition must include its name and the names and attributes of its columns. The definition may include other attributes of the table such as primary key.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Create Physical File (CRTPF) command
 - *CHANGE to the data dictionary if the library into which the table is created is an SQL schema with a data dictionary
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the table is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

To define a foreign key, the privileges held by the authorization ID of the statement must include at least one of the following on the parent table:

- The REFERENCES privilege or object management authority for the table
- The REFERENCES privilege on each column of the specified parent key
- Ownership of the table
- Database administrator authority

If a field procedure is defined, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authority *EXECUTE on the program, and
 - The USAGE privilege on the schema containing the program
- Database administrator authority

If the LIKE clause or AS *select-statement* is specified, the privileges held by the authorization ID of the statement must include at least one of the following on the tables or views specified in these clauses:

- The SELECT privilege for the table or view
 - The LIKE clause and AS *select-statement* using the WITH NO DATA clause do not require *READ authority.
- Ownership of the table or view
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

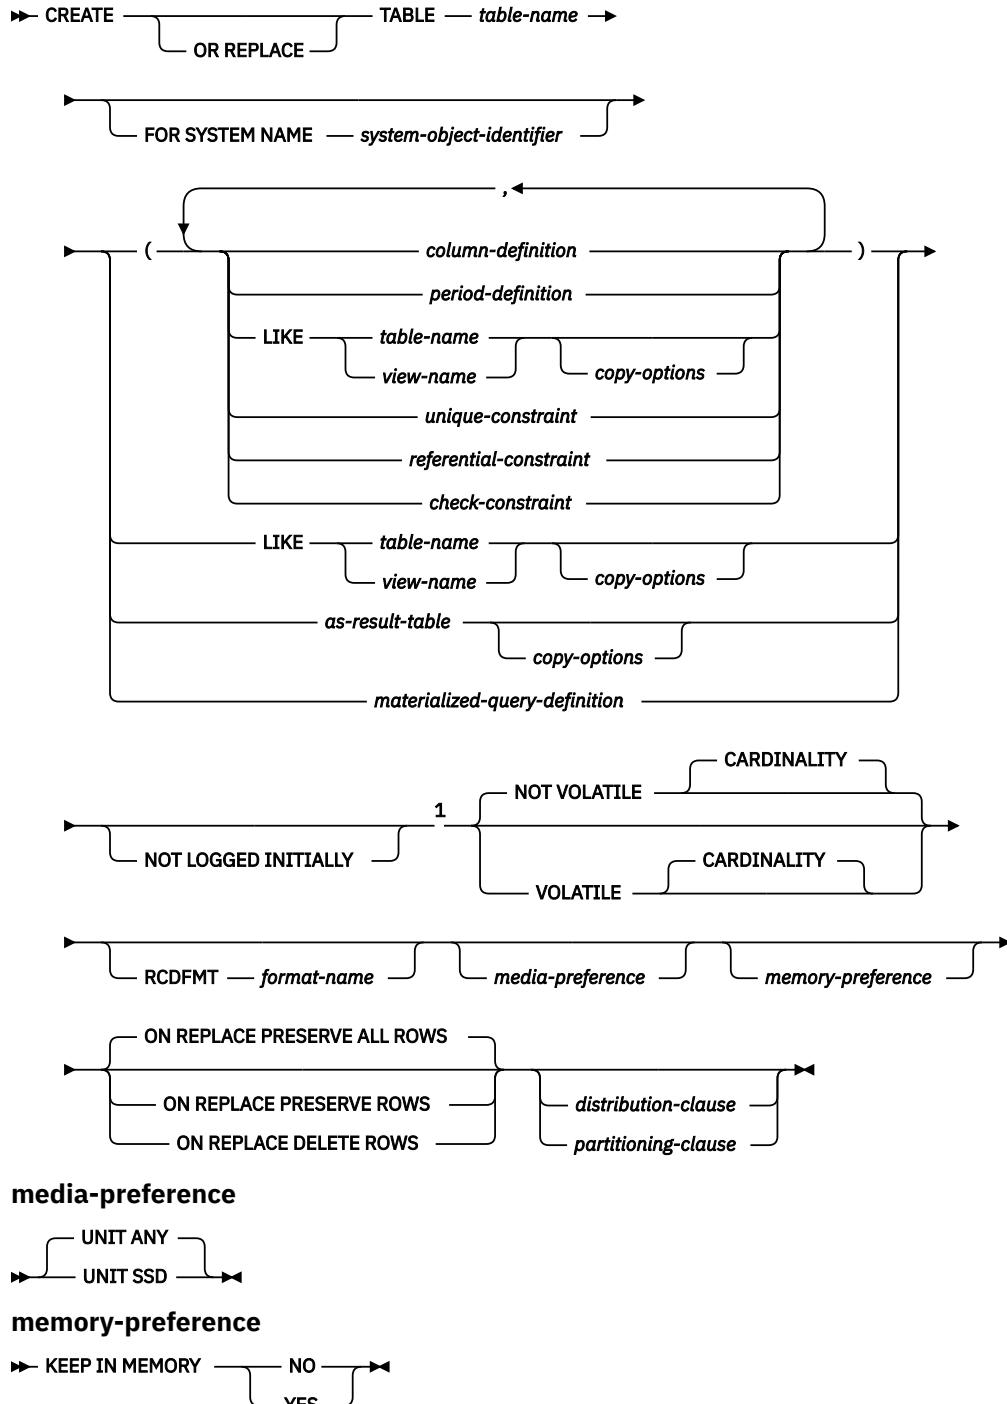

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

To replace an existing table, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the table
 - All authorities needed to DROP the table
 - When ON REPLACE DELETE ROWS clause is used, DELETE privilege on the table
 - When AS *select-statement* is specified, INSERT privilege on the table
- Database administrator authority

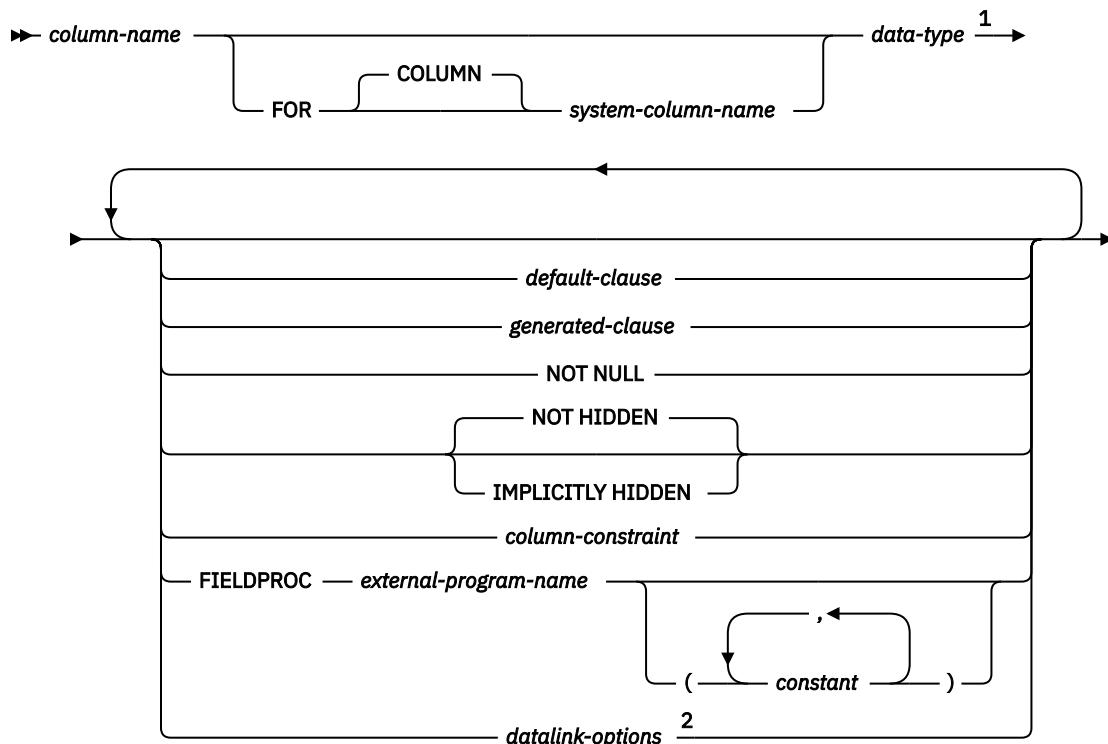

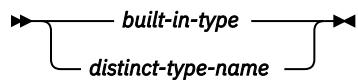

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

Notes:

¹ The optional clauses can be specified in any order.

column-definition**data-type**

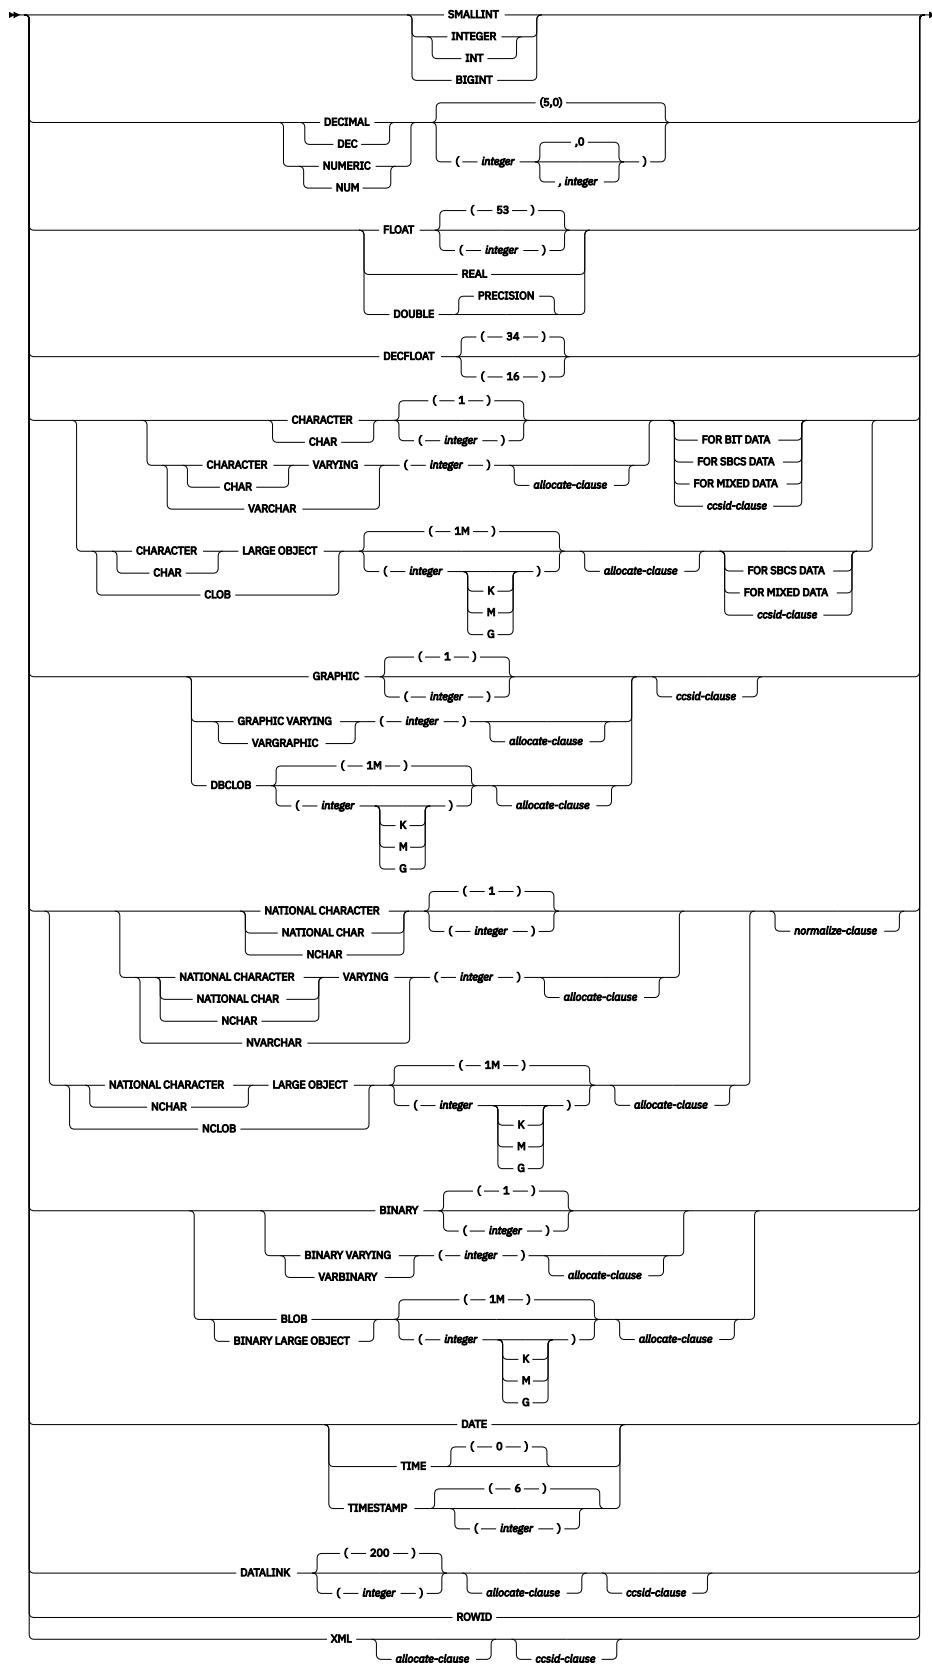

Notes:

¹ *data-type* is optional for row change timestamp columns, row-begin and row-end timestamp columns, and transaction-start-ID timestamp columns.

² The *datalink-options* can only be specified for DATALINKs and distinct types sourced on DATALINKs.

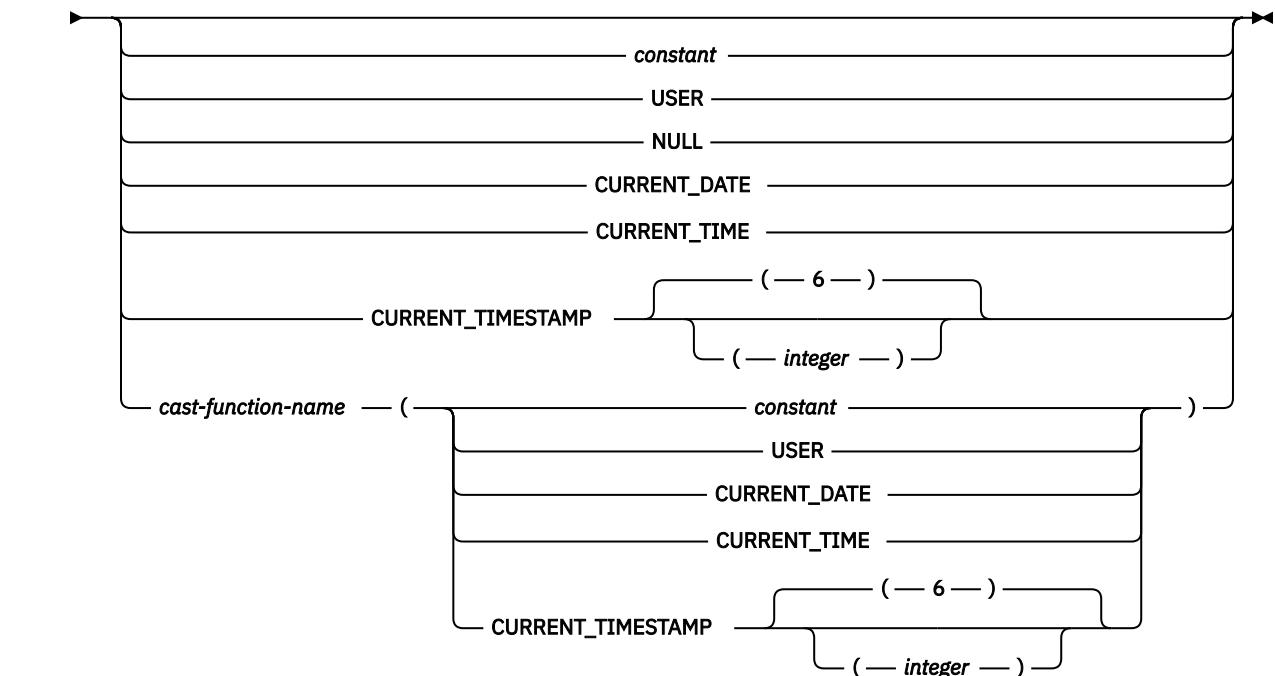

³ The same clause must not be specified more than once.

built-in-type

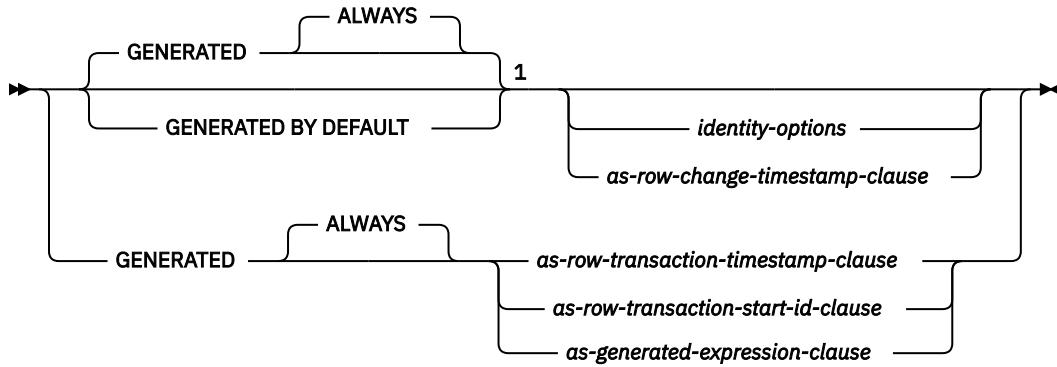

allocate-clause►► ALLOCATE — (— *integer* —) ►►**ccsid-clause**►► CCSID — *integer* — *normalize-clause* ►►**normalize-clause**►► NOT NORMALIZED —
NORMALIZED — ►►**default-clause**

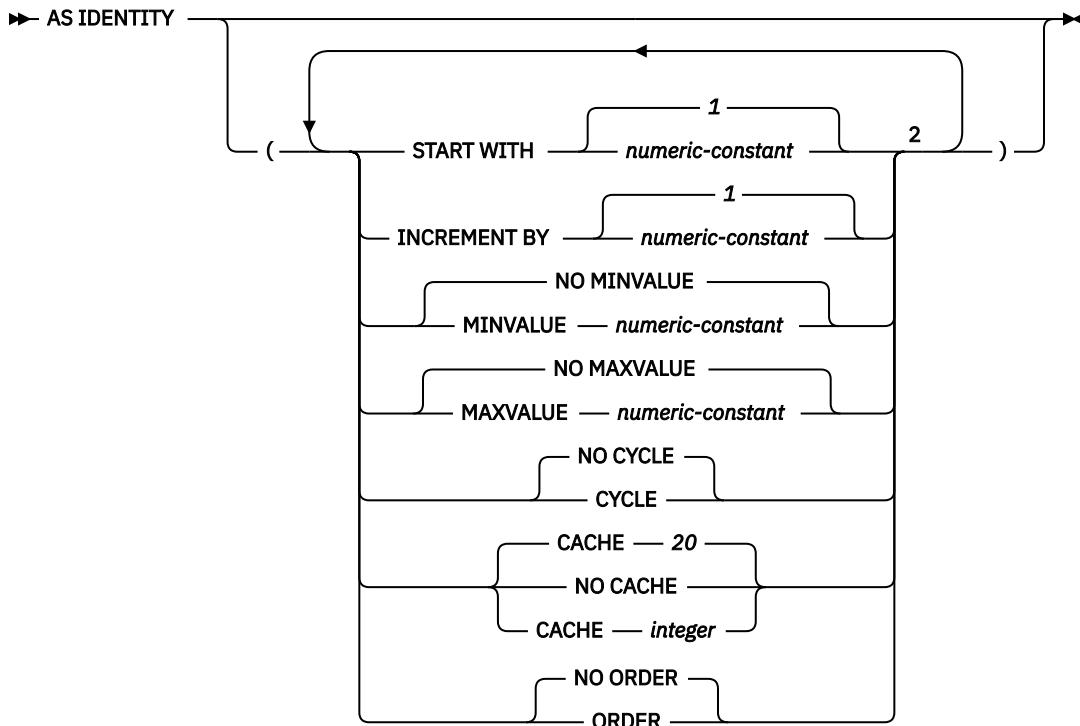

►► WITH DEFAULT →

generated-clause

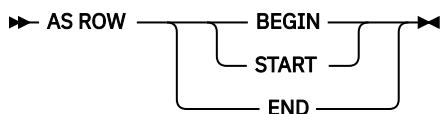

identity-options

as-row-change-timestamp-clause

►► FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP ►►

as-row-transaction-timestamp-clause

as-row-transaction-start-id-clause

►► AS TRANSACTION START ID ►►

Notes:

¹ GENERATED can be specified only if the column has a ROWID data type (or a distinct type that is based on a ROWID data type), or the column is an identity column, or the column is a row change timestamp.

² The same clause must not be specified more than once.

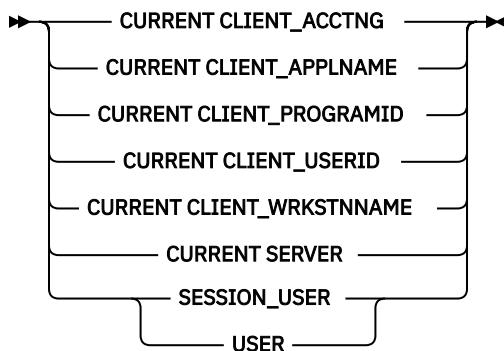

as-generated-expression-clause

►► AS — (— *non-deterministic-expression* —) ►►

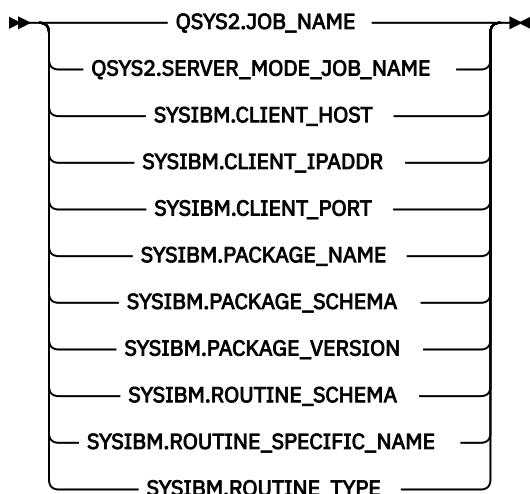

non-deterministic-expression

►► DATA CHANGE OPERATION

 └── *built-in-global-variable* ─────────

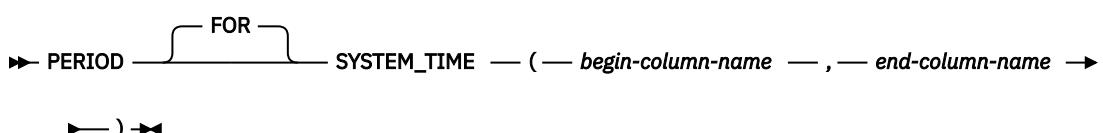

special-register

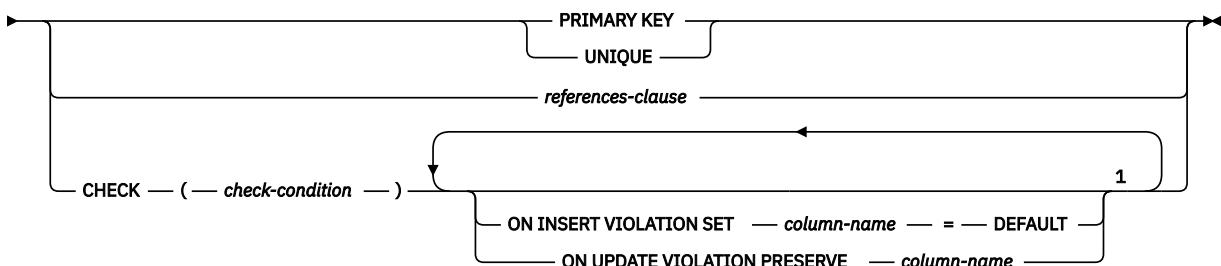

built-in-global-variable

period-definition

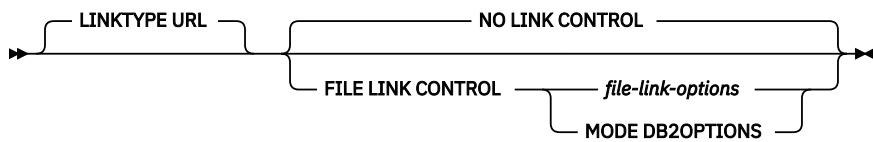

column-constraint

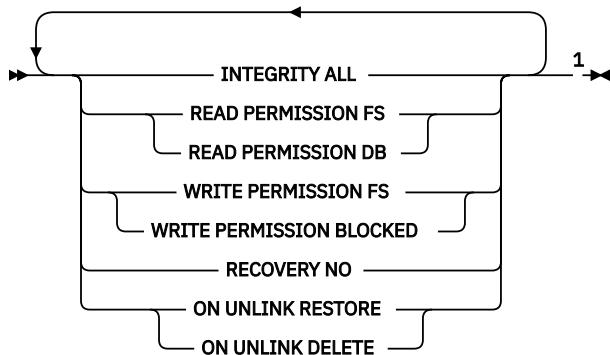

Notes:

¹ The same clause must not be specified more than once.

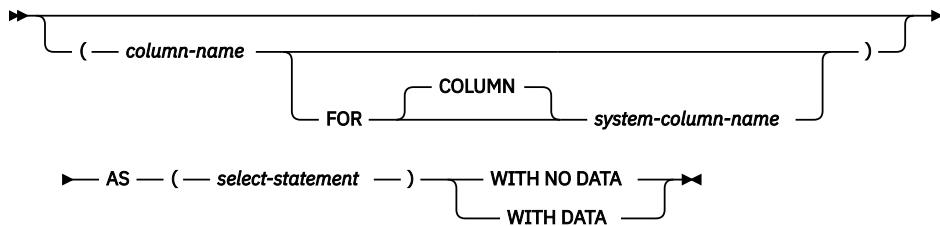

datalink-options

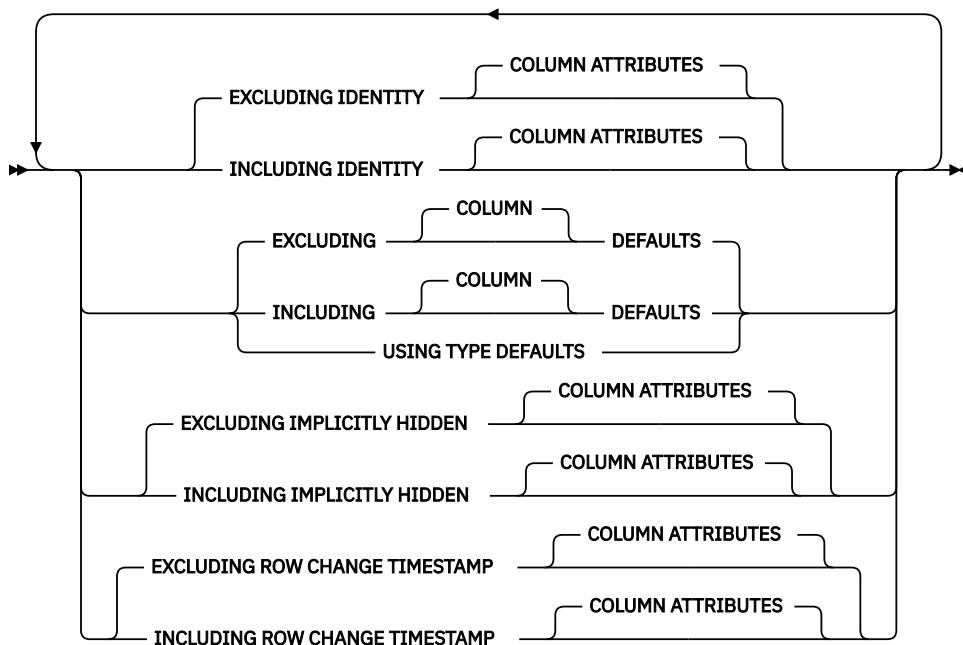

file-link-options

as-result-table

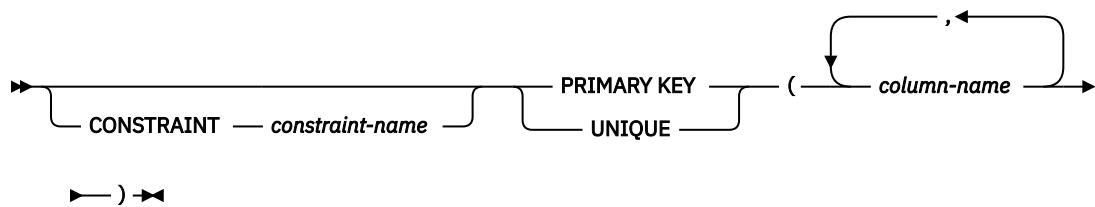

copy-options

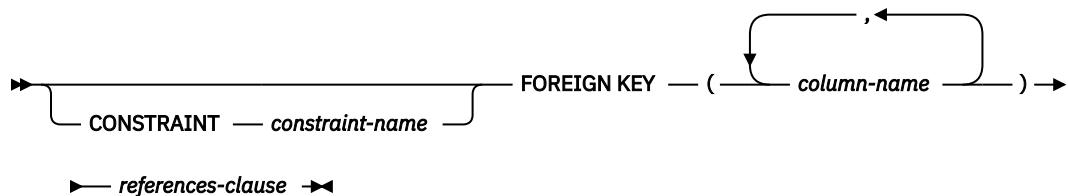

Notes:

¹ All five `file-link-options` must be specified, but they can be specified in any order.

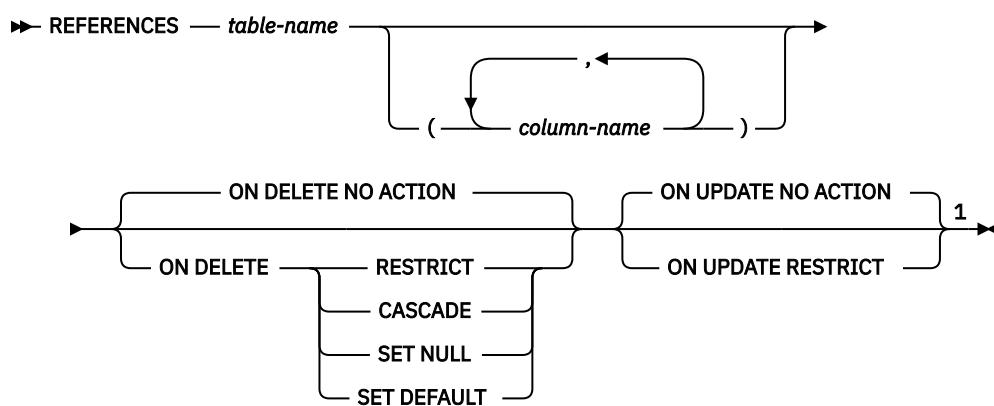

unique-constraint

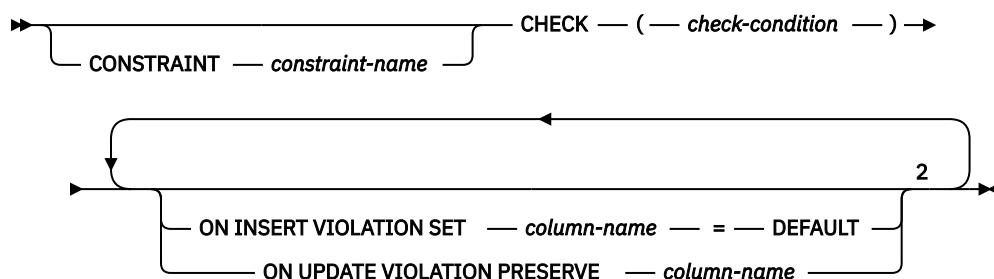

referential-constraint

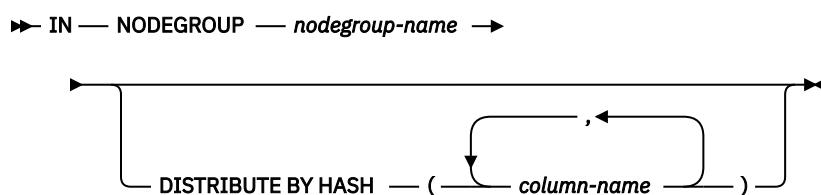

references-clause

check-constraint

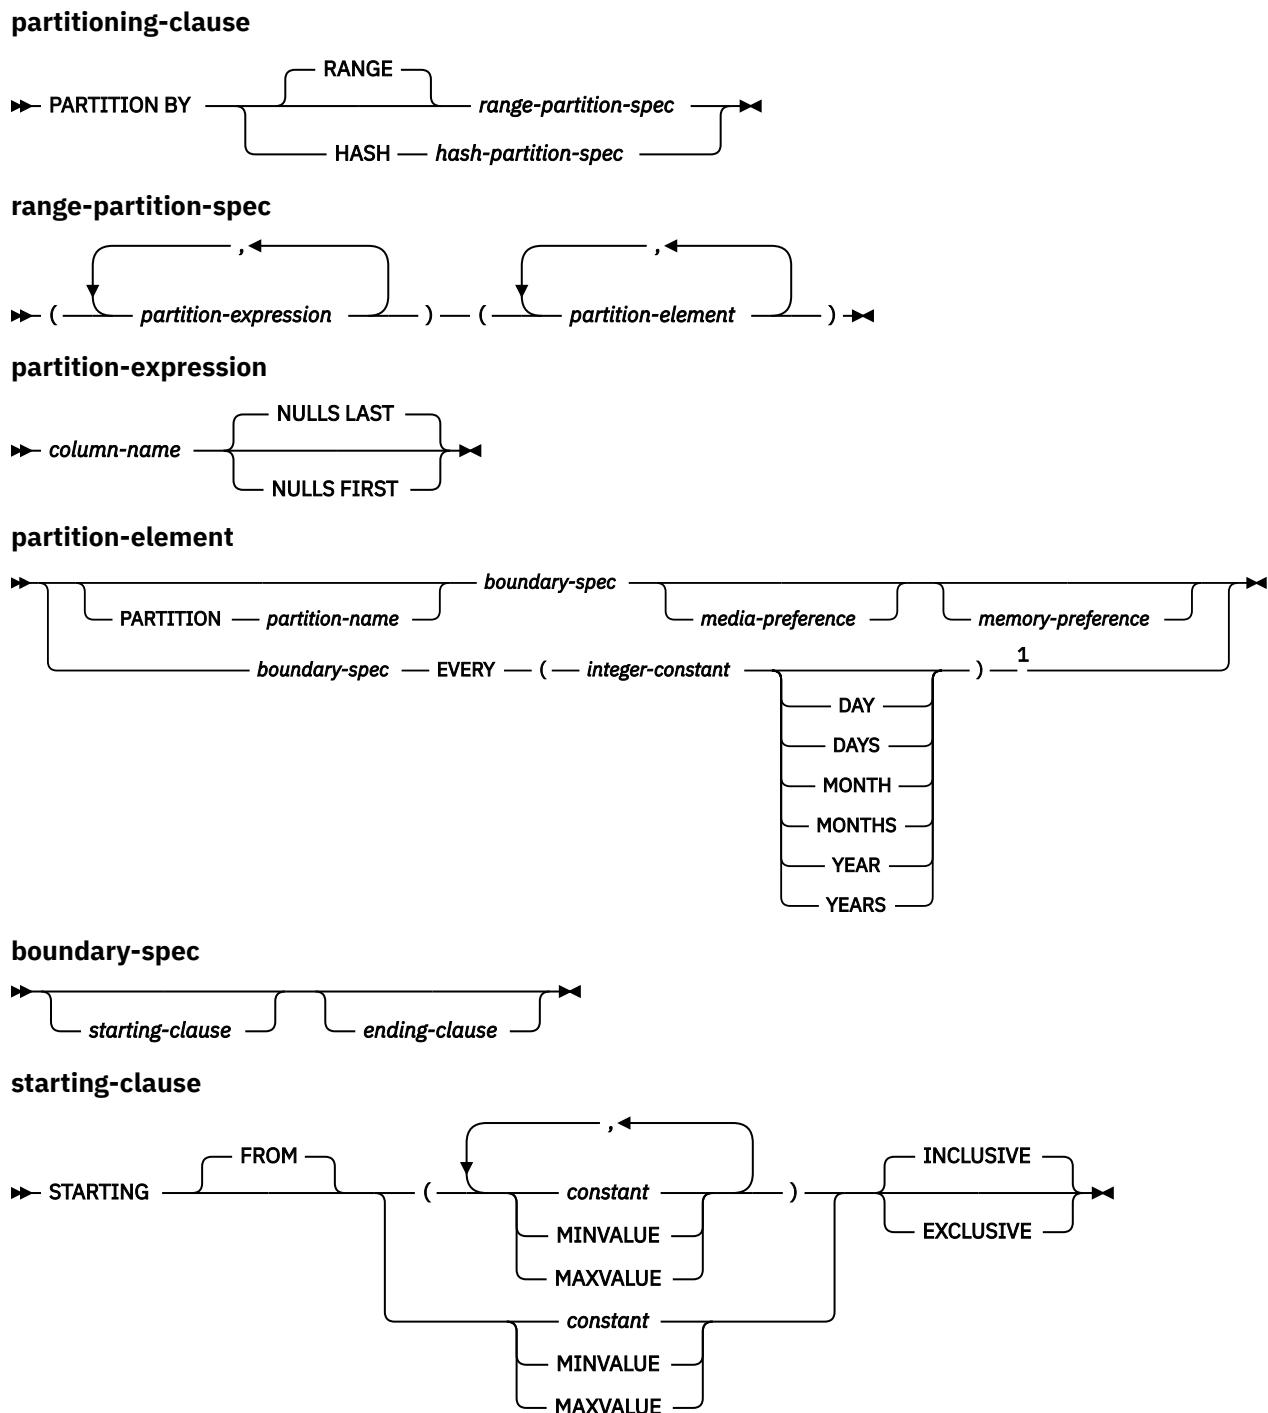

distribution-clause

Notes:

¹ The ON DELETE and ON UPDATE clauses may be specified in either order.

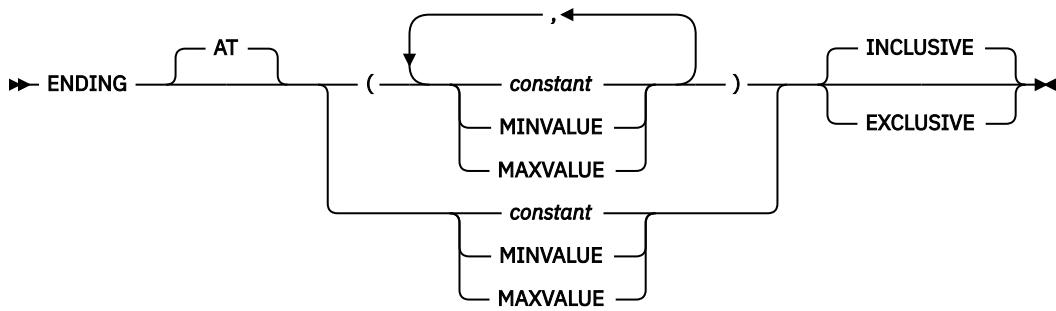

² The same clause must not be specified more than once.

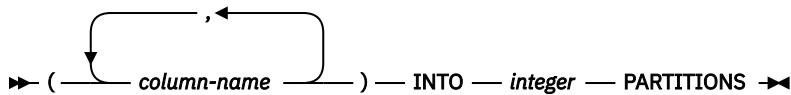

Notes:

¹ This syntax for a *partition-element* is valid if there is only one *partition-expression* with a numeric or datetime data type.

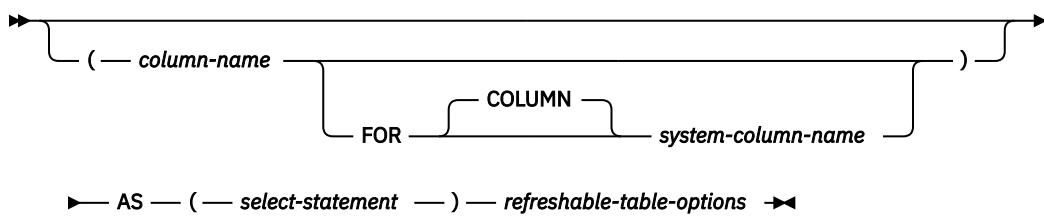

ending-clause

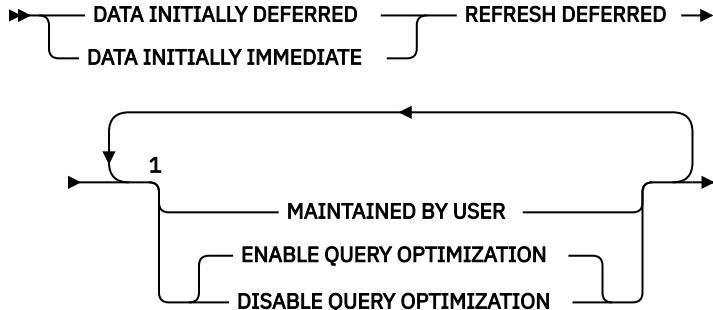

hash-partition-spec

materialized-query-definition

refreshable-table-options

Notes:

¹ The same clause must not be specified more than once. MAINTAINED BY USER must be specified.

Description

OR REPLACE

Specifies to replace the definition for the table if one exists at the current server. The existing definition is effectively altered before the new definition is replaced in the catalog.

A definition for the table exists if:

- FOR SYSTEM NAME is specified and the *system-object-identifier* matches the *system-object-identifier* of an existing table.
- FOR SYSTEM NAME is not specified and *table-name* is a system object name that matches the *system-object-identifier* of an existing table.

If a definition for the table exists and *table-name* is not a system object name, *table-name* can be changed to provide a new name for the table.

This option is ignored if a definition for the table does not exist at the current server.

table-name

Names the table. The name, including the implicit or explicit qualifier, must not identify an alias, file, index, table, or view that already exists at the current server.

If SQL names were specified, the table will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the table will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the table will be created in the current library (*CURLIB).
- Otherwise, the table will be created in the current schema.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the table. *system-object-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *table-name* must not be a valid system object name.

column-definition

Defines the attributes of a column. There must be at least one column definition and no more than 8000 column definitions.

The sum of the row buffer byte counts of the columns must not be greater than 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740. Additionally, if a LOB or XML column is specified, the sum of the row data byte counts of the columns must not be greater than 3 758 096 383 at the time of insert or update. For information about the byte counts of columns according to data type, see “[Maximum row sizes](#)” on page 991.

column-name

Names a column of the table. Do not qualify *column-name* and do not use the same name for more than one column of the table or for a *system-column-name* of the table.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the *system-column-name* is not specified, and the *column-name* is not a valid *system-column-name*, a system column name is generated. For more information about how system column names are generated, see “[Rules for Column Name Generation](#)” on page 993.

data-type

Specifies the data type of the column.

built-in-type

For *built-in-types*, use:

SMALLINT

For a small integer.

INTEGER or INT

For a large integer.

BIGINT

For a big integer.

DECIMAL(*integer, integer*) or DEC(*integer, integer*)**DECIMAL(*integer*) or DEC(*integer*)****DECIMAL or DEC**

For a packed decimal number. The first integer is the precision of the number; that is, the total number of digits; it can range from 1 to 63. The second integer is the scale of the number (the number of digits to the right of the decimal point). It can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0), and DECIMAL for DECIMAL(5,0).

NUMERIC(*integer*,*integer*) or NUM(*integer*,*integer*)

NUMERIC(*integer*) or NUM(*integer*)

NUMERIC or NUM

For a zoned decimal number. The first integer is the precision of the number, that is, the total number of digits; it may range from 1 to 63. The second integer is the scale of the number, (the number of digits to the right of the decimal point). It may range from 0 to the precision of the number.

You can use NUMERIC(*p*) for NUMERIC(*p*,0), and NUMERIC for NUMERIC(5,0).

FLOAT

For a double-precision floating-point number.

FLOAT(*integer*)

For a single- or double-precision floating-point number, depending on the value of *integer*. The value of *integer* must be in the range 1 through 53. The values 1 through 24 indicate single-precision, the values 25 through 53 indicate double-precision. The default is 53.

REAL

For single-precision floating point.

DOUBLE PRECISION or DOUBLE

For double-precision floating point.

DECFLOAT(*integer*)

DECFLAOT

For a IEEE decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, then the DECFLOAT column will be capable of representing 34 significant digits.

CHARACTER(*integer*) or CHAR(*integer*)

CHARACTER or CHAR

For a fixed-length character string of length *integer* bytes. The integer can range from 1 through 32766 (32765 if null capable). If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32766 (32765 if null capable). If the length specification is omitted, a length of 1 is assumed.

CHARACTER VARYING (*integer*) or CHAR VARYING (*integer*) or VARCHAR (*integer*)

For a varying-length character string of maximum length *integer* bytes, which can range from 1 through 32740 (32739 if null capable). If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32740 (32739 if null capable).

CHARACTER LARGE OBJECT (*integer*[K|M|G]) or CHAR LARGE OBJECT (*integer*[K|M|G]) or CLOB (*integer*[K|M|G])

CHARACTER LARGE OBJECT or CHAR LARGE OBJECT or CLOB

For a character large object string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 2 147 483 647. If the length specification is omitted, a length of 1 megabyte is assumed. A CLOB is not allowed in a distributed table.

integer

The maximum value for *integer* is 2 147 483 647. The maximum length of the string is *integer*.

***integer* K**

The maximum value for *integer* is 2 097 152. The maximum length of the string is 1024 times *integer*.

***integer* M**

The maximum value for *integer* is 2 048. The maximum length of the string is 1 048 576 times *integer*.

***integer* G**

The maximum value for *integer* is 2. The maximum length of the string is 1 073 741 824 times *integer*.

GRAPHIC(*integer*)**GRAPHIC**

For a fixed-length graphic string of length *integer*, which can range from 1 through 16383 (16382 if null capable). If the length specification is omitted, a length of 1 is assumed.

VARGRAPHIC(*integer*) or GRAPHIC VARYING(*integer*)

For a varying-length graphic string of maximum length *integer*, which can range from 1 through 16370 (16369 if null capable).

DBCLOB(*integer[K|M|G]*)**DBCLOB**

For a double-byte character large object string of the specified maximum length.

The maximum length must be in the range of 1 through 1 073 741 823. If the length specification is omitted, a length of 1 megabyte is assumed. A DBCLOB is not allowed in a distributed table.

integer

The maximum value for *integer* is 1 073 741 823. The maximum length of the string is *integer*.

integer K

The maximum value for *integer* is 1 028 576. The maximum length of the string is 1024 times *integer*.

integer M

The maximum value for *integer* is 1 024. The maximum length of the string is 1 048 576 times *integer*.

integer G

The maximum value for *integer* is 1. The maximum length of the string is 1 073 741 824 times *integer*.

NATIONAL CHARACTER (*integer*) or NATIONAL CHAR (*integer*) or NCHAR (*integer*)**NATIONAL CHARACTER or NATIONAL CHAR or NCHAR**

For a fixed-length Unicode graphic string of length *integer*, which can range from 1 through 16383 (16382 if null capable). If the length specification is omitted, a length of 1 is assumed. The CCSID is 1200.

NATIONAL CHARACTER VARYING (*integer*) or NATIONAL CHAR VARYING (*integer*) or NCHAR VARYING (*integer*) or NVARCHAR (*integer*)

For a varying-length Unicode graphic string of maximum length *integer*, which can range from 1 through 16370 (16369 if null capable). The CCSID is 1200.

NATIONAL CHARACTER LARGE OBJECT (*integer[K|M|G]*) or NCHAR LARGE OBJECT (*integer[K|M|G]*) or NCLOB(*integer[K|M|G]*)**NATIONAL CHARACTER LARGE OBJECT or NCHAR LARGE OBJECT or NCLOB**

For a Unicode double-byte character large object string of the specified maximum length.

The maximum length must be in the range of 1 through 1 073 741 823. If the length specification is omitted, a length of 1 megabyte is assumed. The CCSID is 1200. An NCLOB is not allowed in a distributed table.

integer

The maximum value for *integer* is 1 073 741 823. The maximum length of the string is *integer*.

integer K

The maximum value for *integer* is 1 028 576. The maximum length of the string is 1024 times *integer*.

integer M

The maximum value for *integer* is 1 024. The maximum length of the string is 1 048 576 times *integer*.

integer G

The maximum value for *integer* is 1. The maximum length of the string is 1 073 741 824 times *integer*.

BINARY(*integer*)**BINARY**

For a fixed-length binary string of length *integer*. The integer can range from 1 through 32766 (32765 if null capable). If the length specification is omitted, a length of 1 is assumed.

BINARY VARYING (*integer*) or VARBINARY(*integer*)

For a varying-length binary string of maximum length *integer*, which can range from 1 through 32740 (32739 if null capable).

BLOB(*integer*[K|M|G]) or BINARY LARGE OBJECT(*integer*[K|M|G])**BLOB or BINARY LARGE OBJECT**

For a binary large object string of the specified maximum length. The maximum length must be in the range of 1 through 2 147 483 647. If the length specification is omitted, a length of 1 megabyte is assumed. A BLOB is not allowed in a distributed table.

integer

The maximum value for *integer* is 2 147 483 647. The maximum length of the string is *integer*.

integer K

The maximum value for *integer* is 2 097 152. The maximum length of the string is 1024 times *integer*.

integer M

The maximum value for *integer* is 2 048. The maximum length of the string is 1 048 576 times *integer*.

integer G

The maximum value for *integer* is 2. The maximum length of the string is 1 073 741 824 times *integer*.

DATE

For a date.

TIME

For a time.

TIMESTAMP(*integer*) or TIMESTAMP

For a timestamp. The integer must be between 0 and 12 and specifies the precision of fractional seconds from 0 (seconds) to 12 (picoseconds). The default is 6 (microseconds).

DATALINK(*integer*) or DATALINK

For a DataLink of the specified maximum length. The maximum length must be in the range of 1 through 32717. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32717. The specified length must be sufficient to contain both the largest expected URL and any DataLink comment. If the length specification is omitted, a length of 200 is assumed. A DATALINK is not allowed in a distributed table.

A DATALINK value is an encapsulated value with a set of built-in scalar functions. The DLVALUE function creates a DATALINK value. The following functions can be used to extract attributes from a DATALINK value.

- DLCOMMENT
- DLLINKTYPE
- DLURLCOMPLETE
- DLURLPATH
- DLURLPATHONLY
- DLURLSCHEME
- DLURLSERVER

A DataLink cannot be part of any index. Therefore, it cannot be included as a column of a primary key, foreign key, or unique constraint.

ROWID

For a row ID. Only one ROWID column is allowed in a table. A ROWID is not allowed in a partitioned table.

XML

For an XML document. Only well-formed documents can be inserted into an XML column. The CCSID for the column cannot be 65535. The maximum length of the column is always 2 147 483 647 bytes.

An XML column has the following restrictions:

- The column cannot be part of any index.
- The column cannot be part of a primary, unique, or foreign key.
- The column cannot be used in a check constraint.
- A default value (WITH DEFAULT) cannot be specified for the column. If the column is nullable, the default for the column is the null value.
- The column cannot be specified in the distribution clause of a distributed table.
- The column cannot be specified in the partitioning clause of a partitioned table.

distinct-type-name

Specifies that the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

ALLOCATE(*integer*)

Specifies for VARCHAR, VARGRAPHIC, VARBINARY, XML, and LOB types the space to be reserved for the column in each row. Column values with lengths less than or equal to the allocated value are stored in the fixed-length portion of the row. Column values with lengths greater than the allocated value are stored in the variable-length portion of the row and require additional input/output operations to retrieve. The allocated value may range from 1 to maximum length of the string, subject to the maximum row buffer size limit. For information about the maximum row buffer size, see “[Maximum row sizes](#)” on page 991. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 to the maximum length of the string. If the allocated length specification is omitted, an allocated length of 0 is assumed. For VARGRAPHIC, the integer is the number of DBCS or Unicode graphic characters. If a constant is specified for the default value and the ALLOCATE length is less than the length of the default value, the ALLOCATE length is assumed to be the length of the default value.

FOR BIT DATA

Specifies that the values of the column are not associated with a coded character set and are never converted. FOR BIT DATA is only valid for CHARACTER or VARCHAR columns. The CCSID of a FOR BIT DATA column is 65535. FOR BIT DATA is not allowed for CLOB columns.

FOR SBCS DATA

Specifies that the values of the column contain SBCS (single-byte character set) data. FOR SBCS DATA is the default for CHAR, VARCHAR, and CLOB columns if the default CCSID at the current server at the time the table is created is not DBCS-capable or if the length of the column is less than 4. FOR SBCS DATA is only valid for CHARACTER, VARCHAR, or CLOB columns. The CCSID of FOR SBCS DATA is determined by the default CCSID at the current server at the time the table is created.

FOR MIXED DATA

Specifies that the values of the column contain both SBCS data and DBCS data. FOR MIXED DATA is the default for CHAR, VARCHAR, and CLOB columns if the default CCSID at the current server at the time the table is created is DBCS-capable and the length of the column is greater than 3. Every FOR MIXED DATA column is a DBCS-open application server field. FOR MIXED DATA is only valid for CHARACTER, VARCHAR, or CLOB columns. The CCSID of FOR MIXED DATA is determined by the default CCSID at the current server at the time the table is created.

CCSID integer

Specifies that the values of the column contain data of CCSID integer. If the integer is an SBCS CCSID, the column is SBCS data. If the integer is a mixed data CCSID, the column is mixed data and the length of the column must be greater than 3. For character columns, the CCSID must be an SBCS CCSID or a mixed data CCSID. For graphic columns, the CCSID must be a DBCS, UTF-16, or UCS-2 CCSID. If a CCSID is not specified for a graphic column, the CCSID is determined by the default CCSID at the current server at the time the table is created. For XML columns, the CCSID must not be 65535. If a CCSID is not specified for an XML column, the CCSID is established at the time the CREATE TABLE is executed according to the SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See “[XML Values](#)” on page 75 for a description of this option. For a list of valid CCSIDs, see [Appendix E, “CCSID values,” on page 1455](#).

CCSID 1208 (UTF-8) or 1200 (UTF-16) data can contain *combining characters*. Combining character support allows a resulting character to be comprised of more than one character. After the first character, up to 300 different non-spacing accent characters (umlauts, accent, etc.) can follow in the data string. If the resulting character is one that is already defined in the character set, that character has more than one representation. *Normalization* replaces the string of combining characters with the hex value of the defined character. This ensures that the same character is represented in a single consistent way. If normalization is not performed, two strings that look identical will not compare equal.

NOT NORMALIZED

The data should not be normalized when passed from the application.

NORMALIZED

The data should be normalized when passed from the application.

DEFAULT

Specifies a default value for the column. This clause cannot be specified more than once in a *column-definition*. DEFAULT cannot be specified for the following types of columns because Db2 generates default values:

- a ROWID column
- an identity column (a column that is defined AS IDENTITY)
- a row change timestamp column
- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

For an XML column, the default is NULL unless NOT NULL is specified; in that case there is no default.

If a value is not specified following the DEFAULT keyword, then:

- if the column is nullable, the default value is the null value.
- if the column is not nullable, the default depends on the data type of the column:

Data type	Default value
Numeric	0
Fixed-length character or graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string length of 0
Date	The current date at the time of INSERT
Time	The current time at the time of INSERT
Timestamp	The current timestamp at the time of INSERT

Data type	Default value
Datalink	A value corresponding to DLVALUE(''URL'')
<i>distinct-type</i>	The default value of the corresponding source type of the distinct type.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

constant

Specifies the constant as the default for the column. The specified constant must represent a value that could be assigned to the column in accordance with the rules of assignment as described in “Assignments and comparisons” on page 83. A floating-point constant or decimal floating-point constant must not be used for a SMALLINT, INTEGER, DECIMAL, or NUMERIC column. A decimal constant must not contain more digits to the right of the decimal point than the specified scale of the column.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value of the column. The data type of the column must be CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the USER special register. The value of the USER special register is not converted to the CCSID of the column.

NULL

Specifies null as the default for the column. If NOT NULL is specified, DEFAULT NULL must not be specified within the same *column-definition*.

NULL is the only default value allowed for a datalink column.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the column must be DATE or a distinct type based on a DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the column must be TIME or a distinct type based on a TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(*integer*)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the column must be TIMESTAMP or a distinct type based on a TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

cast-function-name

This form of a default value can only be used with columns defined as a strongly typed distinct type, BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME or TIMESTAMP data types. The following table describes the allowed uses of these *cast-functions*.

Data Type	Cast Function Name
Strongly typed distinct type N based on a BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
Strongly typed distinct type N based on a DATE, TIME, or TIMESTAMP	N (the user-defined cast function that was generated when N was created) ** or DATE, TIME, or TIMESTAMP *
Strongly typed distinct type N based on other data types	N (the user-defined cast function that was generated when N was created) **

Data Type	Cast Function Name
BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
DATE, TIME, or TIMESTAMP	DATE, TIME, or TIMESTAMP *

Notes:

* The name of the function must match the name of the data type (or the source type of the distinct type) with an implicit or explicit schema name of QSYS2.

** The name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type.

constant

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. For BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, and TIMESTAMP functions, the constant must be a string constant.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the source type of the distinct type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register. The value of the USER special register is not converted to the CCSID of the column.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the source type of the distinct type of the column must be DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the source type of the distinct type of the column must be TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(*integer*)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the source type of the distinct type of the column must be TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

If the value specified is not valid, an error is returned.

GENERATED

Specifies that the database manager generates values for the column. GENERATED may be specified if the column is to be considered one of the following types of columns:

- an identity column
- a row change timestamp column

GENERATED must be specified if the column is to be considered one of the following types of columns:

- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

It may also be specified if the data type of the column is a ROWID (or a distinct type that is based on a ROWID). Otherwise, it must not be specified. GENERATED must not be specified with *default-clause* in a column definition.

ALWAYS

Specifies that the database manager will always generate a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the recommended value.

BY DEFAULT

Specifies that the database manager will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a ROWID column, the database manager uses a specified value, but it must be a valid unique row ID value that was previously generated by the database manager or Db2 for i.

For an identity column or row change timestamp column, the database manager inserts or updates a specified value but does not verify that it is a unique value for the column unless the identity column or row change timestamp column has a unique constraint or a unique index that solely specifies the identity column or row change timestamp column.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. An identity column is not allowed in a distributed table. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

An identity column is implicitly NOT NULL.

START WITH *numeric-constant*

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending sequence and the MAXVALUE for a descending sequence. This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the identity column. The value must not exceed the value of a large integer constant without any non-zero digits existing to the right of the decimal point. The value must be assignable to the column. The default is 1.

If the value is zero or positive, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

MAXVALUE or MINVALUE

Specifies the maximum value at which an ascending identity column either cycles or stops generating values, or a descending identity column cycles to after reaching the minimum value.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column, but the value must be greater than the minimum value.

If a value is not explicitly specified when the identity column is defined, this is the maximum value of the data type for an ascending sequence; or the START WITH value, or -1 if START WITH was not specified, for a descending sequence.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column, but the value must be less than the maximum value.

If a value is not explicitly specified when the identity column is defined, this is the START WITH value, or 1 if START WITH was not specified, for an ascending sequence; or the minimum value of the data type (and precision, if DECIMAL) for a descending sequence.

CACHE or NO CACHE

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table.

CACHE *integer*

Specifies the number of values of the identity column sequence that the database manager preallocates and keeps in memory. The minimum value that can be specified is 2, and the maximum is the largest value that can be represented as an integer. The default is 20.

In certain situations, such as system failure, all cached identity column values that have not been used in committed statements are lost, and thus, will never be used. The value specified for the CACHE option is the maximum number of identity column values that could be lost in these situations.

NO CACHE

Specifies that values for the identity column are not preallocated.

CYCLE or NO CYCLE

Specifies whether this identity column should continue to generate values after reaching either the maximum or minimum value of the sequence.

CYCLE

Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches the maximum value of the sequence, it generates its minimum value. After a descending sequence reaches its minimum value of the sequence, it generates its maximum value. The maximum and minimum values for the column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the database manager for an identity column. If a unique constraint or unique index exists on the identity column, and a non-unique value is generated for it, an error occurs.

NO CYCLE

Specifies that values will not be generated for the identity column once the maximum or minimum value for the sequence has been reached. This is the default.

ORDER or NO ORDER

Specifies whether the identity values must be generated in order of request.

ORDER

Specifies that the values are generated in order of request.

NO ORDER

Specifies that the values do not need to be generated in order of request. This is the default.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp and the values will be generated by the database manager. The database manager generates a value for the column for each row as a row is inserted, and for every row in which any column is updated. The value generated for a row change timestamp column is a timestamp corresponding to the time of the insert or update of the row. If multiple rows are inserted with a single SQL statement, the value for the row change timestamp column may be different for each row to reflect when each row was inserted. The generated value is not guaranteed to be unique.

A table can have only one row change timestamp column. If *data-type* is specified, it must be a TIMESTAMP with a precision of 6 or a distinct type based on a TIMESTAMP with a precision of 6. A row change timestamp column cannot have a DEFAULT clause and must be NOT NULL.

AS ROW BEGIN

Specifies that the column contains timestamp data and that the values are generated by the database manager. The database manager generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same for each row.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ_QAQGINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.

A row-begin column is intended to be used for a system-period temporal table and is required as the first column of a SYSTEM_TIME period. A table can have only one row-begin column. If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). It cannot be a distinct type. The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-begin column is not updatable.

AS ROW END

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated. The assigned value is TIMESTAMP '9999-12-30-0.00.00.000000000000'. For a system-period temporal table, when a row is deleted, the value of the row-end column in the historical row reflects when the row was deleted. If multiple rows are deleted with a single SQL statement, the values for the column in the historical rows are the same.

A row-end column is intended to be used for a system-period temporal table and is required as the second column of a SYSTEM_TIME period. A table can have only one row-end column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). It cannot be a distinct type. The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable and if there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

A transaction-start-ID column is intended to be used for a system-period temporal table and is required for a system-period temporal table. A table can have only one transaction-start-ID column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified it must be TIMESTAMP(12). It cannot be a distinct type. A transaction-start-ID column cannot have a DEFAULT clause. A transaction-start-ID column is not updatable.

DATA CHANGE OPERATION

Specifies that the database manager generates a value for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The column will contain one of the following values:

I
insert operation

U
update operation

D
delete operation

If *data-type* is not specified, the column is defined as CHAR(1). If *data-type* is specified it must be CHAR(1). It cannot be a distinct type. The column cannot have a DEFAULT clause or a field procedure.

special-register

Specifies that the value of a special register is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the special register at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table. It cannot be a distinct type.

Special register	Data type for the column
CURRENT CLIENT_ACCTNG	VARCHAR(255)
CURRENT CLIENT_APPLNAME	VARCHAR(255)
CURRENT CLIENT_PROGRAMID	VARCHAR(255)
CURRENT CLIENT_USERID	VARCHAR(255)
CURRENT CLIENT_WRKSTNNNAME	VARCHAR(255)
CURRENT SERVER	VARCHAR(18)
SESSION_USER	VARCHAR(128)
USER	VARCHAR(18)

The column cannot have a DEFAULT clause or a field procedure.

built-in-global-variable

Specifies that the value of a built-in global variable is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the built-in global variable at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table. It cannot be a distinct type.

Built-in global variable	Data type for the column
QSYS2.JOB_NAME	VARCHAR(28)
QSYS2.SERVER_MODE_JOB_NAME	VARCHAR(28)
SYSIBM.CLIENT_HOST	VARCHAR(255)
SYSIBM.CLIENT_IPADDR	VARCHAR(128)
SYSIBM.CLIENT_PORT	INTEGER
SYSIBM.PACKAGE_NAME	VARCHAR(128)
SYSIBM.PACKAGE_SCHEMA	VARCHAR(128)
SYSIBM.PACKAGE_VERSION	VARCHAR(64)

Built-in global variable	Data type for the column
SYSIBM.ROUTINE_SCHEMA	VARCHAR(128)
SYSIBM.ROUTINE_SPECIFIC_NAME	VARCHAR(128)
SYSIBM.ROUTINE_TYPE	CHAR(1)

The column cannot have a DEFAULT clause or a field procedure.

NOT NULL

Prevents the column from containing null values. Omission of NOT NULL implies that the column can be null. NOT NULL is required for a row change timestamp column, a row-begin column, and a row-end column.

NOT HIDDEN

Indicates the column is included in implicit references to the table in SQL statements. This is the default.

IMPLICITLY HIDDEN

Indicates the column is not visible in SQL statements unless it is referred to explicitly by name. For example, SELECT * does not include any hidden columns in the result. A table must contain at least one column that is not IMPLICITLY HIDDEN.

period-definition

PERIOD FOR

Defines a period for the table.

SYSTEM_TIME (*begin-column-name*, *end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period.

begin-column-name

Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table. *begin-column-name* must not be the same as *end-column-name*. *begin-column-name* must be defined as AS ROW BEGIN.

end-column-name

Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to *end-column-name* in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table. *end-column-name* must be defined as AS ROW END.

column-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

PRIMARY KEY

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

This clause must not be specified in more than one column definition and must not be specified at all if the UNIQUE clause is specified in the column definition. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in the column that makes up the primary key.

UNIQUE

Provides a shorthand method of defining a unique constraint composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE (C) clause is specified as a separate clause.

This clause cannot be specified more than once in a column definition and must not be specified if PRIMARY KEY is specified in the column definition. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

references-clause

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if a *references-clause* is specified in the definition of column C, the effect is the same as if that *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column. The *references-clause* is not allowed if the table is a declared global temporary table, a distributed table, or a history table. The column cannot be a row change timestamp column.

CHECK(*check-condition*)

The CHECK(*check-condition*) of a *column-definition* provides a shorthand method of defining a check constraint whose *check-condition* only references a single column. Thus, if CHECK is specified in the column definition of column C, no columns other than C can be referenced in the *check-condition* of the check constraint. The effect is the same as if the check constraint were specified as a separate clause.

If ON INSERT VIOLATION or ON UPDATE VIOLATION is specified, column C must be referenced in these clauses.

ROWID, XML, and DATALINK with FILE LINK CONTROL columns cannot be referenced in a CHECK constraint. For additional restrictions, see [“check-constraint” on page 979](#).

FIELDPROC

Designates an *external-program-name* as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

constant

Specifies a parameter that is passed to the field procedure when it is invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or DATALINK or a distinct type based on a ROWID or DATALINK. The column must not be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The column must not have a default value of CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The nullability attribute of the encoded and decoded form of the field must match. The column cannot be referenced in a check condition, unless it is referenced in a NULL predicate. If it is part of a foreign key, the corresponding parent key column must use the same field procedure. A field procedure can only be defined for one LOB or XML column with in a table. A field procedure can only be defined for one LOB or XML column with in a table. See [SQL Programming](#) for more details on how to create a field procedure.

datalink-options

Specifies the options associated with a DATALINK data type.

LINKTYPE URL

Defines the type of link as a Uniform Resource Locator (URL).

NO LINK CONTROL

Specifies that there will not be any check made to determine that the linked files exist. Only the syntax of the URL will be checked. There is no database manager control over the linked files.

FILE LINK CONTROL

Specifies that a check should be made for the existence of the linked files. Additional options may be used to give the database manager further control over the linked files.

If FILE LINK CONTROL is specified, each file can only be linked once. That is, its URL can only be specified in a single FILE LINK CONTROL column in a single table.

file-link-options

Additional options to define the level of database manager control of the linked files.

INTEGRITY

Specifies the level of integrity of the link between a DATALINK value and the actual file.

ALL

Any file specified as a DATALINK value is under the control of the database manager and may NOT be deleted or renamed using standard file system programming interfaces.

READ PERMISSION

Specifies how permission to read the file specified in a DATALINK value is determined.

FS

The read access permission is determined by the file system permissions. Such files can be accessed without retrieving the file name from the column.

DB

The read access permission is determined by the database. Access to the file will only be allowed by passing a valid file access token, returned on retrieval of the DATALINK value from the table, in the open operation. If READ PERMISSION DB is specified, WRITE PERMISSION BLOCKED must be specified.

WRITE PERMISSION

Specifies how permission to write to the file specified in a DATALINK value is determined.

FS

The write access permission is determined by the file system permissions. Such files can be accessed without retrieving the file name from the column.

BLOCKED

Write access is blocked. The file cannot be directly updated through any interface. An alternative mechanism must be used to perform updates to the information. For example, the file is copied, the copy updated, and then the DATALINK value updated to point to the new copy of the file.

RECOVERY

Specifies whether the database manager will support point in time recovery of files referenced by values in this column.

NO

Specifies that point in time recovery will not be supported.

ON UNLINK

Specifies the action taken on a file when a DATALINK value is changed or deleted (unlinked). Note that this is not applicable when WRITE PERMISSION FS is used.

RESTORE

Specifies that when a file is unlinked, the DataLink File Manager will attempt to return the file to the owner with the permissions that existed at the time the file was linked. In the case where the user is no longer registered with the file server, the result depends on the file system that contains the files. If the files are in the AIX® file system, the owner is "dfmunknown". If the files are in IFS, the owner is QDLFM. This can only be specified when INTEGRITY ALL and WRITE PERMISSION BLOCKED are also specified.

DELETE

Specifies that the file will be deleted when it is unlinked. This can only be specified when READ PERMISSION DB and WRITE PERMISSION BLOCKED are also specified.

MODE DB2OPTIONS

This mode defines a set of default file link options. The defaults defined by DB2OPTIONS are:

- INTEGRITY ALL
- READ PERMISSION FS
- WRITE PERMISSION FS
- RECOVERY NO

LIKE***table-name or view-name***

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table (*table-name*) or view (*view-name*). The name must identify a table or view that exists at the current server.

The use of LIKE is an implicit definition of n columns, where n is the number of columns in the identified table or view. The implicit definition includes the following attributes of the n columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- FIELDPROC (only copied for *table-name*)

If the LIKE clause is specified immediately following the *table-name* and not enclosed in parenthesis, the following column attributes are also included, otherwise they are not included (the default value, identity, row change timestamp, and hidden attributes can also be controlled by using the *copy-options*):

- Default value, if a *table-name* is specified (*view-name* is not specified)
- Nullability
- Hidden attributes
- Column heading and text (see “[LABEL](#)” on page 1211)

Any REFFLD information for the column will be copied to the new column definition.

If *table-name* contains a row change timestamp column, row-begin column, row-end column, transaction-start-ID column, or a generated expression column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include primary keys, foreign keys, triggers, or a period. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

If the specified table or view is a non-SQL created physical file or logical file, any non-SQL attributes are removed. For example, the date and time format will be changed to ISO.

copy-options**INCLUDING IDENTITY COLUMN ATTRIBUTES or EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table inherits the identity attribute, if any, of the columns resulting from *select-statement*, *table-name*, or *view-name*. In general, the identity attribute is copied if the element of the corresponding column in the table, view, or *select-statement* is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the identity attribute. If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS *select-statement* clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the *select-statement* includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the *select-statement* includes multiple identity columns (that is, a join returned more than one identity column).
- The identity column is included in an expression in the select list.
- The *select-statement* includes a set operation (UNION or INTERSECT).

If INCLUDING IDENTITY is not specified, the table will not have an identity column.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table does not inherit the identity attribute, if any, of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

EXCLUDING COLUMN DEFAULTS or INCLUDING COLUMN DEFAULTS or USING TYPE DEFAULTS

Specifies whether column defaults are inherited.

EXCLUDING COLUMN DEFAULTS

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on INSERT for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that the table inherits the default values of the columns resulting from the *select-statement*, *table-name*, or *view-name*. In general, the default values are copied if the element of the corresponding column in the table, view, or *select-statement* is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with a default value. A default value is the value assigned to a column when a value is not specified on an INSERT.

Do not specify INCLUDING COLUMN DEFAULTS, if you specify USING TYPE DEFAULTS.

If INCLUDING COLUMN DEFAULTS is not specified, the default values are not inherited.

USING TYPE DEFAULTS

Specifies that the default values for the table depend on the data type of the columns that result from the *select-statement*, *table-name*, or *view-name*. If the column is nullable, then the default value is the null value. Otherwise, the default value is as follows:

Data type	Default value
Numeric	0
Fixed-length character or graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string length of 0
Date	The current date at the time of INSERT
Time	The current time at the time of INSERT
Timestamp	The current timestamp at the time of INSERT

Data type	Default value
Datalink	A value corresponding to DLVALUE("URL")
XML	There is no default value
<i>distinct-type</i>	The default value of the corresponding source type of the distinct type.

Do not specify USING TYPE DEFAULTS if INCLUDING COLUMN DEFAULTS is specified.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES or EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies whether implicitly hidden columns are inherited.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table inherits implicitly hidden columns from *select-statement*, *table-name*, or *view-name* and those columns will be defined with the implicitly hidden attribute in the new table.

If INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES is not specified, the table will not have any implicitly hidden columns.

EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table does not inherit implicitly hidden columns from the *fullselect*, *table-name*, or *view-name*.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies whether the row change timestamp attribute is inherited.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table inherits the row change timestamp attribute, if any, of the columns resulting from *select-statement*, *table-name*, or *view-name*. In general, the row change timestamp attribute is copied if the element of the corresponding column in the table, view, or *select-statement* is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the row change timestamp attribute. If the INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES clause is specified with the AS *select-statement* clause, the columns of the new table do not inherit the row change timestamp in the following cases:

- The select list of the *select-statement* includes multiple instances of a row change timestamp column name (that is, selecting the same column more than once).
- The select list of the *select-statement* includes multiple row change timestamp columns (that is, a join returned more than one row change timestamp column).
- The row change timestamp column is included in an expression in the select list.
- The *select-statement* includes a set operation (UNION or INTERSECT).

If INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES is not specified, the table will not have a row change timestamp column.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table does not inherit the row change timestamp attribute, if any, of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

as-result-table

column-name

Names a column in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *select-statement*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *select-statement*.

A list of column names must be specified if the result table of the *select-statement* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation (UNION or INTERSECT) that is not named using the AS clause of the select list.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the *system-column-name* is not specified, and the column-name is not a valid *system-column-name*, a system column name is generated. For more information about how system column names are generated, see [“Rules for Table Name Generation” on page 994](#).

select-statement

Specifies that the columns of the table have the same name and description as the columns that would appear in the derived result table of the *select-statement* if the *select-statement* were to be executed. The use of AS (*select-statement*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *select-statement*.

The implicit definition includes the following attributes of the *n* columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- Nullability
- FIELDPROC
- Column heading and text (see [“LABEL” on page 1211](#))

The following attributes are not included (some attributes can be included by using the *copy-options*):

- Default value
- Hidden attribute
- Identity attributes
- Row change timestamp attribute
- Row-begin, row-end, and transaction-start-ID
- Generated expression

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include a primary key or foreign key from a table. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

Any column in the *select-clause* that is either a direct reference to a column in another table or view or uses only a CAST to change the result attributes will have REFFLD information generated for the definition in the file object.

The *select-statement* must not reference variables, but may reference global variables.

The *select-statement* must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.

If the *select-statement* contains an *isolation-clause* the isolation level specified in the *isolation-clause* applies to the entire SQL statement.

WITH DATA

Specifies that the *select-statement* is executed. After the table is created, the result table rows of the *select-statement* are automatically inserted into the table.

WITH NO DATA

Specifies that the *select-statement* is used only to define the attributes of the new table. The table is not populated using the results of the *select-statement*.

unique-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

PRIMARY KEY(*column-name*,...)

Defines a primary key composed of the identified columns. A table can only have one primary key. Thus, this clause cannot be specified more than once and cannot be specified at all if the shorthand form has been used to define a primary key for the table. The identified columns cannot be the same as the columns specified in another UNIQUE constraint specified earlier in the CREATE TABLE statement. For example, PRIMARY KEY(A,B) would not be allowed if UNIQUE (B,A) had already been specified.

Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766-*n*, where *n* is the number of columns specified that allow nulls. For information about byte-counts see [Table 95 on page 992](#).

The unique index is created as part of the system physical file, not a separate system logical file. When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in any of the columns that make up the primary key.

UNIQUE (*column-name*,...)

Defines a unique constraint composed of the identified columns. The UNIQUE clause can be specified more than once. The identified columns cannot be the same as the columns specified in another UNIQUE constraint or PRIMARY KEY that was specified earlier in the CREATE TABLE statement. For determining if a unique constraint is the same as another constraint specification, the column lists are compared. For example, UNIQUE (A,B) is the same as UNIQUE (B,A).

Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766-*n*, where *n* is the number of columns specified that allows nulls. For information about byte-counts see [Table 95 on page 992](#).

A unique index on the identified column is created during the execution of the CREATE TABLE statement. The unique index is created as part of the system physical file, not as a separate system logical file.

referential-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

FOREIGN KEY

Each specification of the FOREIGN KEY clause defines a referential constraint. FOREIGN KEY is not allowed if the table is a declared global temporary table or a distributed table.

(*column-name*,...)

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and

must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their lengths must not exceed 32766- n , where n is the number of columns specified that allow nulls.

REFERENCES *table-name*

The *table-name* specified in a REFERENCES clause must identify the table being created or a base table that already exists at the application server, but it must not identify a catalog table, a declared temporary table, a distributed table, or a history table. If the parent is a partitioned table, the unique index that enforces the parent unique constraint must be non-partitioned.

A referential constraint is a *duplicate* if its foreign key, parent key, and parent table are the same as the foreign key, parent key, and parent table of a previously specified referential constraint. Duplicate referential constraints are allowed, but not recommended.

Let T2 denote the identified parent table and let T1 denote the table being created.

The specified foreign key must have the same number of columns as the parent key of T2. The description of the n th column of the foreign key and the description of the n th column of that parent key must have identical data types, lengths, CCSIDs, and FIELDPROCs.

(*column-name*,...)

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766- n , where n is the number of columns specified that allow nulls. For information about byte-counts see [Table 95 on page 992](#).

The list of column names must be identical to the list of column names in the primary key of T2 or a UNIQUE constraint that exists on T2. The names need not be specified in the same order as in the primary key; however, they must be specified in corresponding order to the list of columns in the *foreign key* clause. If a column name list is not specified, then T2 must have a primary key. Omission of the column name list is an implicit specification of the columns of that primary key.

The referential constraint specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent.

ON DELETE

Specifies what action is to take place on the dependent tables when a row of the parent table is deleted. There are five possible actions:

- NO ACTION (default)
- RESTRICT
- CASCADE
- SET NULL
- SET DEFAULT

SET NULL must not be specified unless some column of the foreign key allows null values.

CASCADE must not be specified if T1 contains a DataLink column with FILE LINK CONTROL.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let p denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of p in T1.

- If SET NULL is specified, each nullable column of the foreign key of each dependent of p in T1 is set to null. SET NULL is not allowed if the dependent table is a partitioned table and a foreign key column is also a partitioning key.
- If SET DEFAULT is specified, each column of the foreign key of each dependent of p in T1 is set to its default value. SET DEFAULT is not allowed if the dependent table is a partitioned table and a foreign key column is also a partitioning key unless the default keeps the row in the same partition.

ON UPDATE

Specifies what action is to take place on the dependent tables when a row of the parent table is updated.

The update rule applies when a row of T2 is the object of an UPDATE or propagated update operation and that row has dependents in T1. Let p denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are updated.

check-constraint

CONSTRAINT *constraint-name*

Names the check constraint. A *constraint-name* must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

CHECK (*check-condition*)

Defines a check constraint. At any time, the *check-condition* must be true or unknown for every row of the table.

The *check-condition* is a *search-condition* except:

- It can only refer to columns of the table
- The result of any expression in the *check-condition* cannot be a ROWID, XML, or DATALINK with FILE LINK CONTROL data type.
- It must not contain any of the following:
 - Subqueries
 - Aggregate functions
 - TRY_CAST specification
 - Variables
 - Global variables
 - Parameter markers
 - *Sequence-references*
 - Complex expressions that contain LOBs (such as concatenation)
 - OLAP specifications
 - ROW CHANGE expressions
 - IS JSON, JSON_EXISTS, or REGEXP_LIKE predicates
 - Special registers
 - User-defined functions other than functions that were implicitly generated with the creation of a strongly typed distinct type
 - The following built-in scalar functions:

ATAN2	DLURLSERVER	JSON_QUERY	REPLACE
BSON_TO_JSON	DLVALUE	JSON_TO BSON	ROUND_TIMESTAMP
CARDINALITY	ENCRYPT_AES	JSON_VALUE	RPAD

CONTAINS	ENCRYPT_AES256	LOCATE_IN_STRING	SCORE
CURDATE	ENCRYPT_RC2	LPAD	SOUNDEX
CURTIME	ENCRYPT_TDES	MAX_CARDINALITY	TABLE_NAME
DATAPARTITIONNAME	GENERATE_UNIQUE	MONTHNAME	TABLE_SCHEMA
DATAPARTITIONNUM	GETHINT	MONTHS_BETWEEN	TIMESTAMP_FORMAT
DAYNAME	HASH	NEXT_DAY	TIMESTAMPDIFF
DBPARTITIONNAME	HASH_MD5	NOW	TIMESTAMPDIFF_BIG
DECRYPT_BINARY	HASH_SHA1	OVERLAY	TRUNC_TIMESTAMP
DECRYPT_BIT	HASH_SHA256	RAISE_ERROR	VARCHAR_FORMAT
DECRYPT_CHAR	HASH_SHA512	RAND	VERIFY_GROUP_FOR_USER
DECRYPT_DB	IDENTITY_VAL_LOCAL	REGEXP_COUNT	WEEK_ISO
DIFFERENCE	INSERT	REGEXP_INSTR	WRAP
DLURLCOMPLETE ¹	INTERPRET	REGEXP_REPLACE	XMLPARSE
DLURLPATH	JSON_ARRAY	REGEXP_SUBSTR	XMLVALIDATE
DLURLPATHONLY	JSON_OBJECT	REPEAT	XSLTRANSFORM
DLURLSCHEME			

¹ For DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.

ON INSERT VIOLATION

Specifies the action to take if the *check-condition* is false for a row being inserted. If this clause is not specified, an error will occur if the *check-condition* is false for an insert.

SET *column-name* = DEFAULT

The default value for *column-name* is inserted into the table instead of the value provided by the insert operation.

column-name must be referenced in the *check-condition*.

ON UPDATE VIOLATION

Specifies the action to take if the *check-condition* is false for a row being updated. If this clause is not specified, an error will occur if the *check-condition* is false for an update.

PRESERVE *column-name*

The current value for *column-name* remains in the table rather than being replaced by the value provided by the update operation.

column-name must be referenced in the *check-condition*.

For more information about search-condition, see “[Search conditions](#)” on page 208. For more information about check constraints involving LOB data types and expressions, see the [Database Programming](#) topic collection.

NOT LOGGED INITIALLY

Any changes made to the table by INSERT, DELETE, or UPDATE statements in the same unit of work after the table is created by this statement are not logged (journaled).

At the completion of the current unit of work, the NOT LOGGED INITIALLY attribute is deactivated and all operations that are done on the table in subsequent units of work are logged (journaled).

The NOT LOGGED INITIALLY option is useful for situations where a large result set needs to be created with data from an alternate source (another table or a file) and recovery of the table is not necessary. Using this option will save the overhead of logging (journaling) the data.

ACTIVATE NOT LOGGED INITIALLY is ignored if the table has a DATALINK column with FILE LINK CONTROL.

VOLATILE or NOT VOLATILE

Indicates to the optimizer whether the cardinality of table *table-name* can vary significantly at run time. Volatility applies to the number of rows in the table, not to the table itself. The default is NOT VOLATILE.

VOLATILE

Specifies that the cardinality of *table-name* can vary significantly at run time, from empty to large. To access the table, the optimizer will typically use an index, if possible.

NOT VOLATILE

Specifies that the cardinality of *table-name* is not volatile. Access plans that reference this table will be based on the cardinality of the table at the time the access plan is built. NOT VOLATILE is the default.

RCDFMT

Indicates the record format name of the table.

RCDFMT *format-name*

An unqualified name that designates the IBM i record format name of the table. A *format-name* is a system identifier.

If a record format name is not specified, the *format-name* is the same as the *system-object-name* of the table.

media-preference

Specifies the preferred storage media for the table or partition.

UNIT ANY

No storage media is preferred. Storage for the table or partition will be allocated from any available storage media. If UNIT ANY is specified on the table, any *media-preference* that is specified on a partition is used.

UNIT SSD

Solid state disk storage media is preferred. Storage for the table or partition may be allocated from solid state disk storage media, if available. If UNIT SSD is specified on the table, any *media-preference* specified on a partition is ignored.

memory-preference

KEEP IN MEMORY

Specifies whether the data for the table should be brought into a main storage pool when the data is used in a query.

NO

The data will not be brought into a main storage pool.

YES

The data will be brought into a main storage pool.

ON REPLACE

Specifies the action to take when replacing a table that exists at the current server. This option is ignored if an existing table is not being replaced.

PRESERVE ALL ROWS

Current rows of the specified table will be preserved. PRESERVE ALL ROWS is not allowed if WITH DATA is specified with *result-table-as*.

All rows of all partitions in a partitioned table are preserved. If the new table definition is a range partitioned table, the defined ranges must be able to contain all the rows from the existing partitions.

If a column is dropped, the column values will not be preserved. If a column is altered, the column values may be modified.

If the table is not a partitioned table or is a hash partitioned table, PRESERVE ALL ROWS and PRESERVE ROWS are equivalent.

PRESERVE ROWS

Current rows of the specified table will be preserved. PRESERVE ROWS is not allowed if WITH DATA is specified with *result-table-as*.

If a partition of a range partitioned table is dropped, the rows of that partition will be deleted without processing any delete triggers. To determine if a partition of a range partitioned table is dropped, the range definitions and the partition names (if any) of the partitions in the new table definition are compared to the partitions in the existing table definition. If either the specified range or the name of a partition matches, it is preserved. If a partition does not have a *partition-name*, its *boundary-spec* must match an existing partition.

If a partition of a hash partition table is dropped, the rows of that partition will be preserved.

If a column is dropped, the column values will not be preserved. If a column is altered, the column values may be modified.

DELETE ROWS

Current rows of the specified table will be deleted. Any existing DELETE triggers are not fired.

DELETE ROWS is not allowed if the table is a system-period temporal table or a history table.

distribution-clause

IN NODEGROUP *nodegroup-name*

Specifies the nodegroup across which the data in the table will be distributed. The name must identify a nodegroup that exists at the current server. If this clause is specified, the table is created as a distributed table across all the systems in the nodegroup.

A LOB, DATALINK, XML, or IDENTITY column is not allowed in a distributed table.

The Db2 Multisystem product must be installed to create a distributed table. For more information about distributed tables, see the [Db2 Multisystem topic collection](#).

DISTRIBUTE BY HASH (*column-name*,...)

Specifies the partitioning key. The partitioning key is used to determine on which node in the nodegroup a row will be placed. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. If the DISTRIBUTE BY clause is not specified, the first column of the primary key is used as the partitioning key. If there is no primary key, the first column of the table that is not floating point, date, time, or timestamp is used as the partitioning key.

The columns that make up the partitioning key must be a subset of the columns that make up any unique constraints over the table. Floating point, date, time, timestamp, LOB, XML, DataLink, ROWID, and columns that have a field procedure cannot be used in a partitioning key.

partitioning-clause

PARTITION BY RANGE

Specifies that ranges of column values are used to determine the target data partition when inserting a row into the table. The number of partitions must not exceed 256.

partition-expression

Specifies the key data over which the range is defined to determine the target data partition of the data.

column-name

Identifies a column in the data partitioning key. The partitioning key is used to determine into which partition in the table a row will be placed. The *column-name* must be an unqualified

name that identifies a column of the table. The same column must not be identified more than once.

LOB, XML, DataLink, ROWID, row change timestamp columns, identity columns, and any column with a field procedure cannot be used in a partitioning key.

The number of identified columns must not exceed 120. The sum of length attributes of the columns must not be greater than 2000.

NULLS LAST

Indicates that null values compare high.

NULLS FIRST

Indicates that null values compare low.

partition-element

Specifies ranges for a data partitioning key.

PARTITION *partition-name*

Names the data partition. The name must not be the same as any other data partition for the table.

If the clause is not specified, a unique partition name is generated by the database manager.

boundary-spec

Specifies the boundaries of a range partition. If more than one partition key is specified, the boundaries must be specified in ascending sequence. The ranges must not overlap.

starting-clause

Specifies the low end of the range for a data partition. The number of specified starting values must be the same as the number of columns in the partitioning key. If a *starting-clause* is not specified for the first *boundary-spec*, the default is MINVALUE INCLUSIVE for each column of the partitioning key. If a *starting-clause* is not specified for a subsequent *boundary-spec*, the previous adjacent *boundary-spec* must contain an *ending-clause*. The default is the same as that *ending-clause* except that the INCLUSIVE or EXCLUSIVE attribute is reversed.

STARTING FROM

Introduces the *starting-clause*.

constant

Specifies a constant that must conform to the rules of a constant for the data type of the corresponding column of the partition key. If the corresponding column of the partition key is a distinct type, the constant must conform to the rules of the source type of the distinct type. The value must not be in the range of any other *boundary-spec* for the table.

MINVALUE

Specifies a value that is lower than the lowest possible value for the data type of the *column-name* to which it corresponds. If MINVALUE is specified, all subsequent values in the *starting-clause* must also be MINVALUE.

MAXVALUE

Specifies a value that is greater than the greatest possible value for the data type of the *column-name* to which it corresponds. If MAXVALUE is specified, all subsequent values in the *ending-clause* must also be MAXVALUE.

INCLUSIVE

Indicates that the specified range values are included in the data partition.

EXCLUSIVE

Indicates that the specified range values are excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

ending-clause

Specifies the high end of the range for a data partition. The number of specified ending values must be the same as the number of columns in the data partitioning key. An

ending-clause must be specified for the last *boundary-spec*. If an *ending-clause* is not specified for a previous *boundary-spec*, the next adjacent *boundary-spec* must contain a *starting-clause*. The default is the same as that *starting-clause* except that the INCLUSIVE or EXCLUSIVE attribute is reversed.

ENDING AT

Introduces the *ending-clause*.

constant

Specifies a constant that must conform to the rules of a constant for the data type of the corresponding column of the partition key. If the corresponding column of the partition key is a distinct type, the constant must conform to the rules of the source type of the distinct type. The value must not be in the range of any other *boundary-spec* for the table.

MINVALUE

Specifies a value that is lower than the lowest possible value for the data type of the *column-name* to which it corresponds. If MINVALUE is specified, all subsequent values in the *starting-clause* must also be MINVALUE.

MAXVALUE

Specifies a value that is greater than the greatest possible value for the data type of the *column-name* to which it corresponds. If MAXVALUE is specified, all subsequent values in the *ending-clause* must also be MAXVALUE.

INCLUSIVE

Indicates that the specified range values are included in the data partition.

EXCLUSIVE

Indicates that the specified range values are excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

EVERY *integer-constant*

Specifies that multiple data partitions will be added where *integer-constant* specifies the width of each data partition range. If EVERY is specified, only a single SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, DATE, or TIMESTAMP column can be specified for the partition key.

The starting value of the first data partition is the specified STARTING value. The starting value of each subsequent partition is the starting value of the previous partition + *integer-constant*. If the *starting-clause* specified EXCLUSIVE, the starting value of every partition is EXCLUSIVE. Otherwise, the starting value of every partition is INCLUSIVE.

The ending value of every partition of the range is (the partition's start value + *integer-constant*). If the *ending-clause* specified EXCLUSIVE, the ending value of the last partition is EXCLUSIVE. Otherwise, the ending value of the last partition is INCLUSIVE. The ending values of the other partitions is EXCLUSIVE if the starting value is INCLUSIVE. Otherwise, the ending values of the other partitions is INCLUSIVE.

The number of partitions added is determined by adding *integer-constant* repeatedly to the STARTING value until the ENDING value is reached. For example:

```
CREATE TABLE FOO
(A INT)
PARTITION BY RANGE(A)
(STARTING(1) ENDING(10) EVERY(2))
```

is equivalent to the following CREATE TABLE statement:

```
CREATE TABLE FOO
(A INT)
PARTITION BY RANGE(A)
(STARTING(1) ENDING(2),
 STARTING(3) ENDING(4),
 STARTING(5) ENDING(6),
 STARTING(7) ENDING(8),
 STARTING(9) ENDING(10))
```

In the case of dates and timestamps, the EVERY value must be a labeled duration. For example:

```
CREATE TABLE FOO
  (A DATE)
  PARTITION BY RANGE(A)
    (STARTING('2001-01-01') ENDING('2010-01-01') EVERY(3 MONTHS))
```

PARTITION BY HASH

Specifies that the hash function is used to determine the target data partition when inserting a row into the table.

(*column-name*,...)

Specifies the partitioning key. The partitioning key is used to determine into which partition in the table a row will be placed. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once.

Floating point, LOB, XML, date, time, timestamp, DataLink, ROWID, identity columns, and columns with a field procedure cannot be used in a partitioning key.

INTO *integer* PARTITIONS

Specifies the number of partitions. The number of partitions must not exceed 256.

materialized-query-definition

column-name

Names a column in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *select-statement*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *select-statement*.

A list of column names must be specified if the result table of the *select-statement* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation (UNION or INTERSECT) that is not named using the AS clause of the select list.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the *system-column-name* is not specified, and the column-name is not a valid *system-column-name*, a system column name is generated. For more information about how system column names are generated, see [“Rules for Table Name Generation” on page 994](#).

select-statement

Specifies that the columns of the table have the same name and description as the columns that would appear in the derived result table of the *select-statement* if the *select-statement* were to be executed. The use of AS (*select-statement*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *select-statement*.

The implicit definition includes the following attributes of the *n* columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- Nullability
- FIELDPROC
- Column heading and text (see [“LABEL” on page 1211](#))

The following attributes are not included:

- Default value

- Hidden attribute
- Identity attributes
- Row change timestamp attribute
- Row-begin, row-end, and transaction-start-ID
- Generated expression

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include a primary key or foreign key from a table. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

The *select-statement* must not refer to variables or global variables, or include parameter markers. If an expression in the SELECT clause of the *select-statement* is not a column name, then the expression must not reference a column with a field procedure.

The *select-statement* must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.

refreshable-table-options

Specifies that the table is a *materialized query table* and the REFRESH TABLE statement can be used to populate the table with the results of the *select-statement*.

A materialized query table whose *select-statement* contains a GROUP BY clause is summarizing data from the tables referenced in the *select-statement*. Such a materialized query table is also known as a *summary table*. A summary table is a specialized type of materialized query table.

When a materialized query table is defined, the following *select-statement* restrictions apply:

- The *select-statement* cannot contain a reference to another materialized query table or to a view that refers to a materialized query table.
- The *select-statement* cannot contain a reference to a declared temporary table, a table in QTEMP, a program-described file, or a non-SQL logical file in the FROM clause.
- The *select-statement* cannot contain a *data-change-table-reference*.
- The *select-statement* cannot contain a reference to a view that references another materialized query table or a declared temporary table. When a materialized query table is defined with ENABLE QUERY OPTIMIZATION, the *select-statement* cannot contain a reference to a view that contains one of the restrictions from the following paragraph.
- The *select-statement* cannot contain an expression with a DataLink or a distinct type based on a DataLink where the DataLink is FILE LINK CONTROL.
- The *select-statement* cannot contain a result column that is not an SQL data type, such as binary with precision, DBCS-ONLY, or DBCS-EITHER.

When a materialized query table is defined with ENABLE QUERY OPTIMIZATION, the following additional *select-statement* restrictions apply:

- Must not include any special registers.
- Must not include any non-deterministic functions.
- The ORDER BY clause is allowed, but is only used by REFRESH. It may improve locality of reference of data in the materialized query table.
- If the subselect references a view, the *select-statement* in the view definition must satisfy the preceding restrictions.

DATA INITIALLY DEFERRED

Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a materialized query table.

DATA INITIALLY IMMEDIATE

Specifies that the data is inserted into the materialized query table when it is created.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user. The user can use INSERT, DELETE, UPDATE, or REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization. The default is ENABLE QUERY OPTIMIZATION.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the *select-statement* specified does not satisfy the restrictions for query optimization, an error is returned.

DISABLE QUERY OPTIMIZATION

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

If row level or column level access control is activated for any table that is directly or indirectly referenced in the *select-statement*, row access control is implicitly activated for the table being created. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table will return a warning that there is no data in the table. To provide access to the materialized query table, an appropriate row permission can be created or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate.

Notes

Table attributes: Tables are created as physical files. When a table is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Physical File (CRTPF) command.

SQL tables are created so that space used by deleted rows will be reclaimed by future insert requests. This attribute can be changed via the command CHGPF and specifying the REUSEDLT(*NO) parameter. For more information about the CHGPF command, see [CL Reference](#).

A distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see [Db2 Multisystem](#).

Table journaling: When a table is created, journaling may be automatically started.

- If the table is created into a schema that has specified (using the STRJRNLIB command) that journaling should implicitly be started.
- If the schema has not specified that journaling should be started, journaling will be started to a journal called QSQJRN if it exists in the same schema that the table is created into.

Table ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the table is created exists, the *owner* of the table is that user profile.
- Otherwise, the *owner* of the table is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the table is the user profile or group user profile of the thread executing the statement.

Table authority: If SQL names are used, tables are created with the system authority of *EXCLUDE to *PUBLIC. If system names are used, tables are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the table is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the table.

REPLACE rules: When a table is recreated by REPLACE using PRESERVE ROWS, the new definition of the table is compared to the old definition and logically, for each difference between the two, a corresponding ALTER operation is performed. When the DELETE ROWS option is used, the table is logically dropped and recreated; as long as objects dependent on the table remain valid, any modification is allowed. For more information see [Table 90 on page 757](#) in ALTER TABLE. For columns, constraints, and partitions, the comparisons are performed based on their names and attributes.

Column names and system column names can be changed by modifying either the column name or the system column name, leaving the other name unchanged. If neither name matches an existing column, a new column is created. The existence of another object dependent on a column name may prevent the name change.

New definition vs existing definition	Equivalent ALTER TABLE action
Column	
Column exists in both and the attributes are the same	No change
Column exists in both and the attributes are different	ALTER COLUMN
Column exists only in new table definition	ADD COLUMN
Column exists only in existing table definition	DROP COLUMN RESTRICT
Constraint	
Constraint exists in both and is the same	No change
Constraint exists in both and is different	DROP constraint RESTRICT and ADD constraint
Constraint exists only in new table definition	ADD constraint
Constraint exists only in existing table definition	DROP constraint RESTRICT
<i>materialized-query-definition</i>	
<i>materialized-query-definition</i> exists in both and is the same	No change
<i>materialized-query-definition</i> exists in both and is different	ALTER MATERIALIZED QUERY
<i>materialized-query-definition</i> exists only in new table definition	ADD MATERIALIZED QUERY
<i>materialized-query-definition</i> exists only in existing table definition	DROP MATERIALIZED QUERY
<i>partitioning-clause</i>	
<i>partitioning-clause</i> exists in both and is the same	No change
<i>partitioning-clause</i> exists in both and is different	ADD PARTITION, DROP PARTITION, and ALTER PARTITION
<i>partitioning-clause</i> exists only in new table definition	ADD <i>partitioning-clause</i>
<i>partitioning-clause</i> exists only in existing table definition	DROP PARTITIONING
PERIOD	

New definition vs existing definition	Equivalent ALTER TABLE action
PERIOD exists in both and is the same	No change
PERIOD exists only in new table definition	ALTER ADD PERIOD
PERIOD exists only in existing table definition	ALTER DROP PERIOD A period cannot be dropped if the table is a system-period temporal table
NOT LOGGED INITIALLY	
NOT LOGGED INITIALLY exists in both	No change
NOT LOGGED INITIALLY exists only in new table definition	NOT LOGGED INITIALLY
NOT LOGGED INITIALLY exists only in existing table definition	Logged initially
VOLATILE	
VOLATILE attribute exists in both and is the same	No change
VOLATILE attribute exists only in new table definition	VOLATILE
VOLATILE attribute exists only in existing table definition	NOT VOLATILE
<i>media-preference</i>	
<i>media-preference</i> exists in both and is the same	No change
<i>media-preference</i> exists only in new table definition	ALTER <i>media-preference</i>
<i>media-preference</i> exists only in existing table definition	UNIT ANY
<i>memory-preference</i>	
<i>memory-preference</i> exists in both and is the same	No change
<i>memory-preference</i> exists only in new table definition	ALTER <i>memory-preference</i>
<i>memory-preference</i> exists only in existing table definition	KEEP IN MEMORY NO

Any attributes that cannot be specified in the CREATE TABLE statement are preserved:

- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved. However, unlike other objects, REPLACE of a table will generate a ZC (change object) journal audit entry.
- Current data journaling is preserved.
- Comments and labels and column headings are preserved unless the REPLACE uses the AS clause.
- Triggers are preserved, if possible. If it is not possible to preserve a trigger, an error is returned.
- Masks and permissions are preserved, if possible. If it is not possible to preserve a mask or permission, an error is returned.
- Temporal table VERSIONING and the history table are preserved.

- Any views, materialized query tables, and indexes dependent on the table will be preserved or recreated, if possible. If it is not possible to preserve a dependent view, materialized query table, or index, an error is returned.

Using an identity column: When a table has an identity column, the database manager can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys.

Identity columns and ROWID columns are similar in that both types of columns contain values that the database manager generates. ROWID columns can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40-byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time (using RMVJRNCHG), it is possible that a large gap in the sequence of generated values for the identity column might result. For example, assume a table has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and the database manager subsequently generates values up to 1000. Now, assume that the table is recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

When CYCLE is specified duplicate values for a column may be generated even when the column is GENERATED ALWAYS, unless a unique constraint or unique index is defined on the column.

Creating materialized query tables: To ensure that the materialized query table has data before being used by a query:

- DATA INITIALLY IMMEDIATE should be used to create materialized query tables, or
- the materialized query table should be created with query optimization disabled and then enable the table for query optimization after it is refreshed.

The isolation level at the time when the CREATE TABLE statement is executed is the isolation level for the materialized query table. The *isolation-clause* can be used to explicitly specify the isolation level.

Considerations for implicitly hidden columns: A column that is defined as implicitly hidden is not part of the result table of a query that specifies * in a SELECT list. However, an implicitly hidden column can be explicitly referenced in a query. For example, an implicitly hidden column can be referenced in the SELECT list or in a predicate in a query. Additionally, an implicitly hidden column can be explicitly referenced in a COMMENT statement, CREATE INDEX statement, ALTER TABLE statement, INSERT statement, MERGE statement, or UPDATE statement. An implicitly hidden column can be referenced in a referential constraint. A REFERENCES clause that does not contain a column list refers implicitly to the primary key of the parent table. It is possible that the primary key of the parent table includes a column defined as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition explicitly refers to an implicitly hidden column, that column will be part of the materialized query table.

If the SELECT list of the fullselect of a view definition (CREATE VIEW statement) explicitly refers to an implicitly hidden column, that column will be part of the view, however the view column is not considered 'hidden'.

Considerations for transaction-start-ID columns: A transaction-start-ID column contains a null value if the column allows null values and there is a row-begin column and the value of the row-begin column is unique from values for row-begin columns generated for other transactions. Given that the column may contain null values, it is recommended that one of the following methods be used when retrieving a value from the column:

```
COALESCE (transaction_start_id_col, row_begin_col)
CASE WHEN transaction_start_id_col IS NOT NULL
```

```
THEN transaction_start_id_col  
ELSE row_begin_col END
```

Defining a system-period temporal table: A system-period temporal table definition includes the following:

- A system period named SYSTEM_TIME, which is defined using a row-begin column and a row-end column. See the descriptions of AS ROW BEGIN, AS ROW END, and period-definition.
- A transaction-start-ID column. See the description of AS TRANSACTION START ID.
- A system-period data versioning definition specified on a subsequent ALTER TABLE statement that specifies the ADD VERSIONING action, which includes the name of the associated history table. See “[ADD VERSIONING USE HISTORY TABLE history-table-name](#)” on page 746.

Partitioned table performance: The larger the number of partitions in a partitioned table, the greater the overhead in SQL data change and SQL data statements. You should create a partitioned table with the minimum number of partitions that are required to minimize this overhead. It

Creating a table using a remote select-statement: The *select-statement* for an *as-result-table* can refer to tables on a different server than where the table is being created. This can be done by using a three-part object name or an alias that is defined to reference a three-part name of a table or view. The *select-statement* cannot be for a materialized query table and the result cannot contain a column that has a field procedure defined. If the remote server is Db2 for LUW or Db2 for z/OS, *copy-options* are not allowed. If the remote server is Db2 for LUW, a column list should be explicitly specified before the AS keyword.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- INLINE LENGTH is a synonym for ALLOCATE.
- *constraint-name* (without the CONSTRAINT keyword) may be specified following the FOREIGN KEY keywords in a *referential-constraint*
- DEFINITION ONLY is a synonym for WITH NO DATA
- PARTITIONING KEY is a synonym for DISTRIBUTE BY HASH.
- PART is a synonym for PARTITION.
- PARTITION *partition-number* may be specified instead of PARTITION *partition-name*. A *partition-number* must not identify a partition that was previously specified in the CREATE TABLE statement.
If a *partition-number* is not specified, a unique partition number is generated by the database manager.
- VALUES is a synonym for ENDING AT.
- SUMMARY between CREATE and TABLE when creating a materialized query table.

Maximum row sizes

There are two maximum row size restrictions referred to in the description of *column-definition*.

- The maximum row buffer size is 32766 or, if a VARCHAR, VARGRAPHIC, VARBINARY, LOB, or XML column is specified, 32740.
- The maximum row data size is 3 758 096 383 if a LOB or XML column is specified; this size is determined when a row is inserted or updated. If a LOB or XML column is not specified, then the maximum row data size is 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740.

To determine the length of a row buffer and row data or both, add the corresponding length of each column of that row based on the byte counts of the data type.

The follow table gives the byte counts of columns by data type for columns that do not allow null values. If any column allows null values, one byte is required for every eight columns. A column that has a field procedure could have a different count based on the result of the field procedure.

Table 95. Byte Counts of Columns by Data Type

Data Type	Row Buffer Byte Count	Row Data Byte Count
SMALLINT	2	2
INTEGER	4	4
BIGINT	8	8
DECIMAL(p, s)	The integral part of $(p/2) + 1$	The integral part of $(p/2) + 1$
NUMERIC(p, s)	p	p
FLOAT (single precision)	4	4
FLOAT (double precision)	8	8
DECFLOAT(16)	8	8
DECFLOAT(34)	16	16
CHAR(n)	n	n
VARCHAR(n)	$n+2$	$n+2$
CLOB(n)	$29+pad$	$n+29$
GRAPHIC(n)	n^2	n^2
VARGRAPHIC (n)	n^2+2	n^2+2
DBCLOB(n)	$29+pad$	n^2+29
BINARY(n)	n	n
VARBINARY(n)	$n+2$	$n+2$
BLOB(n)	$29+pad$	$n+29$
DATE	10	4
TIME	8	3
TIMESTAMP(p)	when p is 0, 19; otherwise $20+p$	The integral part of $((p+1)/2) + 7$
DATALINK(n)	$n+24$	$n+24$
ROWID	42	28
XML	$29+pad$	2 147 483 647
<i>distinct-type</i>	The byte count for the source type.	The byte count for the source type.

Notes:

pad is a value from 1 to 15 necessary for boundary alignment.

Precision as described to the database:

- Floating-point fields are defined in the Db2 for i database with a decimal precision, not a bit precision. The algorithm used to convert the number of bits to decimal is $\text{decimal precision} = \text{CEILING}(n/3.31)$, where n is the number of bits to convert. The decimal precision is used to determine how many digits to display using interactive SQL.
- SMALLINT fields are stored with a decimal precision of 4,0.
- INTEGER fields are stored with a decimal precision of 9,0.

- BIGINT fields are stored with a decimal precision of 19,0.

LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY

The non-standard syntax of LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY is supported, but deprecated. The alternative standard syntax of VARCHAR(integer), VARGRAPHIC(integer), and VARBINARY(integer) is preferred. VARCHAR(integer), VARGRAPHIC(integer), and VARBINARY(integer) are recommended. After the CREATE TABLE statement is processed, the database manager considers a LONG VARCHAR column to be VARCHAR, a LONG VARGRAPHIC column to be VARGRAPHIC, and a LONG VARBINARY column to be VARBINARY. The maximum length is calculated in a product-specific fashion that is not portable.

LONG VARCHAR¹⁰¹

For a varying length character string whose maximum length is determined by the amount of space available in the row.

LONG VARGRAPHIC¹⁰¹

For a varying length graphic string whose maximum length is determined by the amount of space available in the row.

LONG VARBINARY¹⁰¹

For a varying length binary string whose maximum length is determined by the amount of space available in the row.

The maximum length of a LONG column is determined as follows. Let:

- i be the sum of the row buffer byte counts of all columns in the table that are not LONG VARCHAR, LONG VARGRAPHIC, or LONG VARBINARY
- j be the number of LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY columns in the table
- k be the number of columns in the row that allow nulls.

The length of each LONG VARCHAR and LONG VARBINARY column is $\text{INTEGER}((32716 - i - ((k+7)/8))/j)$.

The length of each LONG VARGRAPHIC column is determined by taking the length calculated for a LONG VARCHAR column and dividing it by 2. The integer portion of the result is the length.

Rules for System Name Generation

There are specific instances when the system generates a system table, view, index, or column name. These instances and the name generation rules are described in the following sections.

Rules for Column Name Generation

A system-column-name is generated if the system-column-name is not specified when a table or view is created and the column-name is not a valid system-column-name.

If the column-name does not contain special characters and is longer than 10 characters, a 10-character system-column-name will be generated as:

- The first 5 characters of the name
- A 5 digit unique number

For example:

```
The system-column-name for LONGCOLUMNNAME would be LONGC00001
```

If the column name is delimited:

- The first 5 characters from within the delimiters will be used as the first 5 characters of the system-column-name. If there are fewer than 5 characters within the delimiters, the name will be padded on

¹⁰¹ This option is provided for compatibility with other products. It is recommended that VARCHAR(integer), VARGRAPHIC(integer), or VARBINARY(integer) be specified instead.

the right with underscore (_) characters. Lower case characters are folded to upper case characters. The only valid characters in a system-column-name are: A-Z, 0-9, @, #, \$, and _. Any other characters will be changed to the underscore (_) character. If the first character ends up as an underscore, it will be changed to the letter Q.

- A 5 digit unique number is appended to the 5 characters.

For example:

```
The system-column-name for "abc" would be ABC__00001  
The system-column-name for "COL2.NAME" would be COL2_00001  
The system-column-name for "C 3" would be C_3_00001  
The system-column-name for "?" would be Q____00001  
The system-column-name for "*column1" would be QCOLU00001
```

Rules for Table Name Generation

A system name will be generated if a table, view, alias, or index is created without using the FOR SYSTEM NAME clause and has either:

- A name longer than 10 characters
- A name that contains characters not valid in a system name

The SQL name or its corresponding system name may both be used in SQL statements to access the file once it is created. However, the SQL name is only recognized by Db2 for i and the system name must be used in other environments.

There are two separate methods for generating the system name:

- If a data area with the name QGENOBJNAM exists in the same schema that the table is created into, the user can influence the generated name.

The data area is subject to the following restrictions:

- The user must be authorized to read the data area.
- The data area must have an attribute of CHAR(10).
- The first 5 characters of the data area value must be '?????'.
- The next 5 characters of the data area value must contain 5 numeric digits.

If any of the above conditions are not satisfied or any error occurs while accessing the starting value in the data area, the default name generation rules will be used as if the data area did not exist at all.

If the data area meets all of the restrictions above, the generated name will be the same as if the default name generation rules below except that after the first 5 (or 4) characters of the name, the unique number will initially contain the 5 digits specified in the data area (instead of '00001' or '0001').

For example, if the value of the data area was '?????00999':

```
The system name for "?" would be "__00999"  
The system name for "longtablename" would be "lon00999"  
The system name for "LONGTableName" would be LONG00999  
The system name for "A b " would be "A_b00999"
```

- Otherwise, the default name generation rules are used:

If the name does not contain special characters and is longer than 10 characters, a 10-character system name will be generated as:

- The first 5 characters of the name
- A 5 digit unique number

For example:

```
The system name for LONGTABLENAME would be LONGT00001
```

If the SQL name contains special characters, the system name is generated as:

- The first 4 characters of the name
- A 4 digit unique number

In addition:

- All special characters are replaced by the underscore (_)
- Any trailing blanks are removed from the name
- The name is delimited by double quotes ("") if the delimiters are required for the name to be a valid system name.

For example:

```
The system name for "???" would be "__0001"
The system name for "longtablename" would be "long0001"
The system name for "LONGTableName" would be LONG0001
The system name for "A b " would be "A_b0001"
```

SQL ensures the system name is unique by searching the cross reference file. If the name already exists in the cross reference file, the number is incremented until the name is no longer a duplicate.

If a unique name cannot be determined using the above rules, an additional character is added to the counter in the name, and the number is incremented until a unique name can be found or the range is exhausted. For example, if creating "longtablename" and names "long0001" through "long9999" already exist, the name would become "lon00001".

Examples

Example 1: Given database administrator authority, create a table named 'ROSSITER.INVENTORY' with the following columns:

Part number

Small integer, must not be null

Description

Character of length 0 to 24, allows nulls

Quantity on hand,

Integer allows nulls

```
CREATE TABLE ROSSITER.INVENTORY
(PARTNO      SMALLINT     NOT NULL,
DESCR        VARCHAR(24),
QONHAND     INT)
```

Example 2: Create a table named DEPARTMENT with the following columns:

Department number

Character of length 3, must not be null

Department name

Character of length 0 through 36, must not be null

Manager number

Character of length 6

Administrative dept.

Character of length 3, must not be null

Location name

Character of length 16, allows nulls

The primary key is column DEPTNO.

```
CREATE TABLE DEPARTMENT
(DEPTNO      CHAR(3)      NOT NULL,
DEPTNAME    VARCHAR(36)   NOT NULL,
MGRNO       CHAR(6),
ADMREDEPT  CHAR(3)      NOT NULL,
```

```
LOCATION CHAR(16),
PRIMARY KEY(DEPTNO)
```

Example 3: Create a table named REORG_PROJECTS which has the same column definitions as the columns in the view PRJ_LEADER.

```
CREATE TABLE REORG_PROJECTS
LIKE PRJ_LEADER
```

Example 4: Create an EMPLOYEE2 table with an identity column named EMP_NO. Define the identity column so that Db2 for i will always generate the values for the column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

```
CREATE TABLE EMPLOYEE2
( EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
  ID SMALLINT,
  NAME CHAR(30),
  SALARY DECIMAL(5,2),
  DEPTNO SMALLINT)
```

Example 5: Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contains daily summary data for the date and amount of a transaction.

```
CREATE TABLE STRANS
AS (SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
  FROM TRANS
 GROUP BY YEAR, MONTH, DAY )
DATA INITIALLY DEFERRED
REFRESH DEFERRED
MAINTAINED BY USER
```

Example 6: Create a table, *policy_info*, that uses a SYSTEM_TIME period and create a history table, *hist_policy_info*. Then issue an ALTER TABLE statement to associate the *policy_info* table with the *hist_policy_info* table.

```
CREATE TABLE policy_info
(policy_id CHAR(10) NOT NULL,
 coverage INT NOT NULL,
 sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
 sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
 create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
 PERIOD SYSTEM_TIME(sys_start,sys_end));

CREATE TABLE hist_policy_info
(policy_id CHAR(10) NOT NULL,
 coverage INT NOT NULL,
 sys_start TIMESTAMP(12) NOT NULL,
 sys_end TIMESTAMP(12) NOT NULL,
 create_id TIMESTAMP(12));

ALTER TABLE policy_info
ADD VERSIONING USE HISTORY TABLE hist_policy_info;
```

The history table can also be created in the following way since the generated attributes are not copied for LIKE:

```
CREATE TABLE hist_policy_info
LIKE policy_info;
```

CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- Each of the following:
 - The ALTER privilege on the table or view on which the trigger is defined,
 - The SELECT privilege on the table or view on which the trigger is defined,
 - The SELECT privilege on any table or view referenced in the *search-condition* in the *trigger-action*,
 - The UPDATE privilege on the table on which the trigger is defined, if the BEFORE UPDATE trigger contains a SET statement that modifies the NEW correlation variable,
 - The privileges required to execute each *triggered-SQL-statement*, and
 - The USAGE privilege on the schema containing the table or view on which the trigger is defined.
- Database administrator authority

If an INSTEAD OF trigger is added to a view that is not inherently updatable, the *OBJMGT system authority is also required on the view.

In addition, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE on the Add Physical File Trigger (ADDPFTRG) command,
 - *USE on the Create Program (CRTPGM) command
- Database administrator authority

If the SECURED attribute is specified, or the trigger is secured and OR REPLACE is specified :

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority” on page 15](#).

If SQL names are specified, and a user profile exists that has the same name as the library into which the trigger is created, and the name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- *ALLOBJ and *SECADM special authority
- Database administrator authority

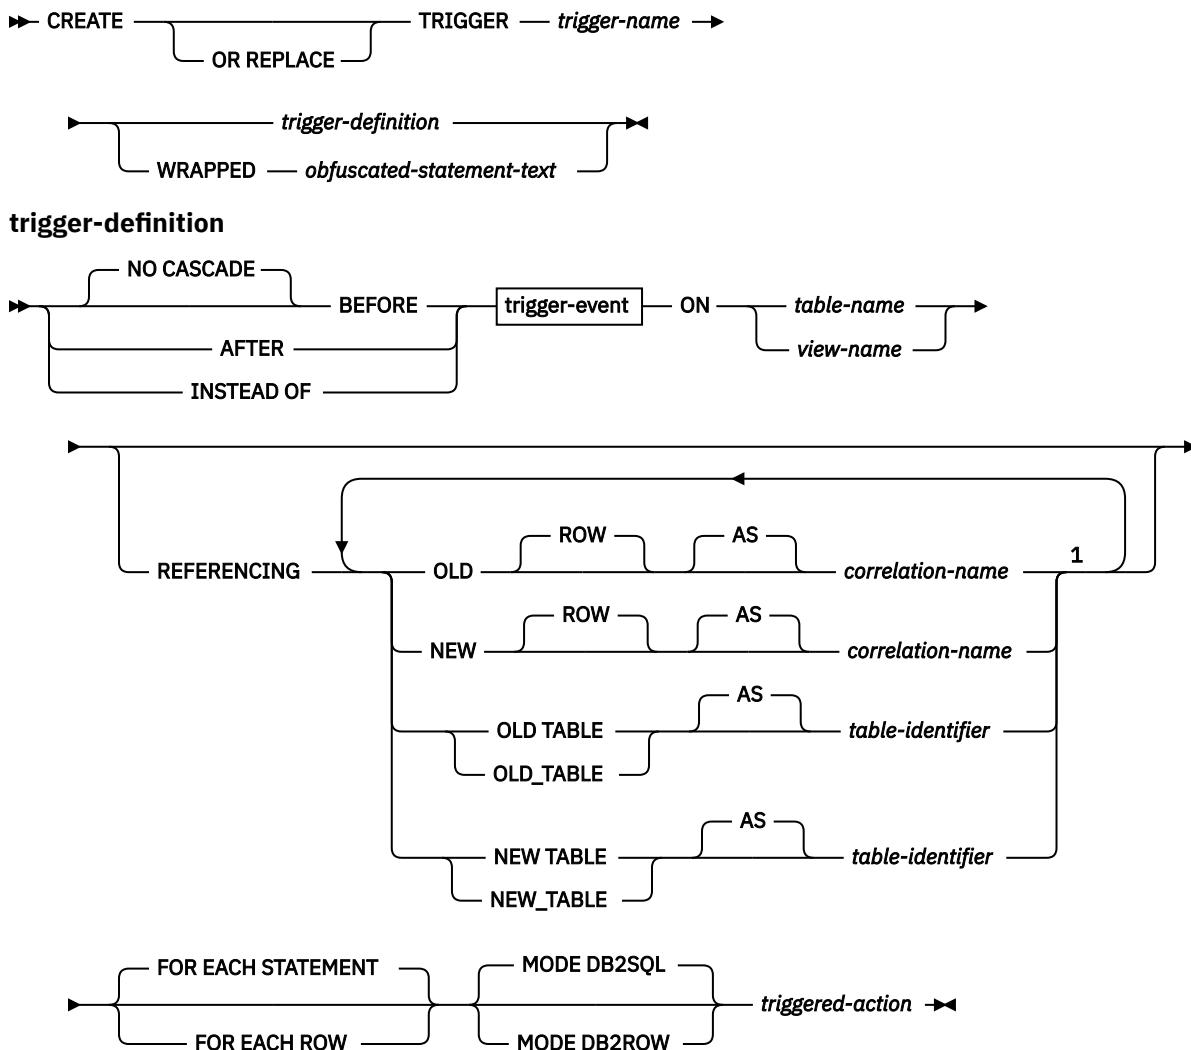

To replace an existing trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the trigger program object
 - All authorities needed to DROP the trigger

- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

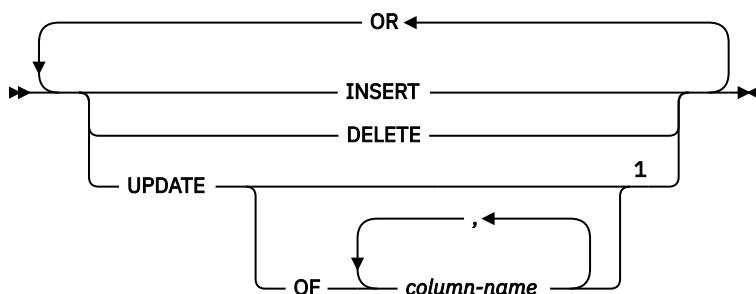

Syntax

Notes:

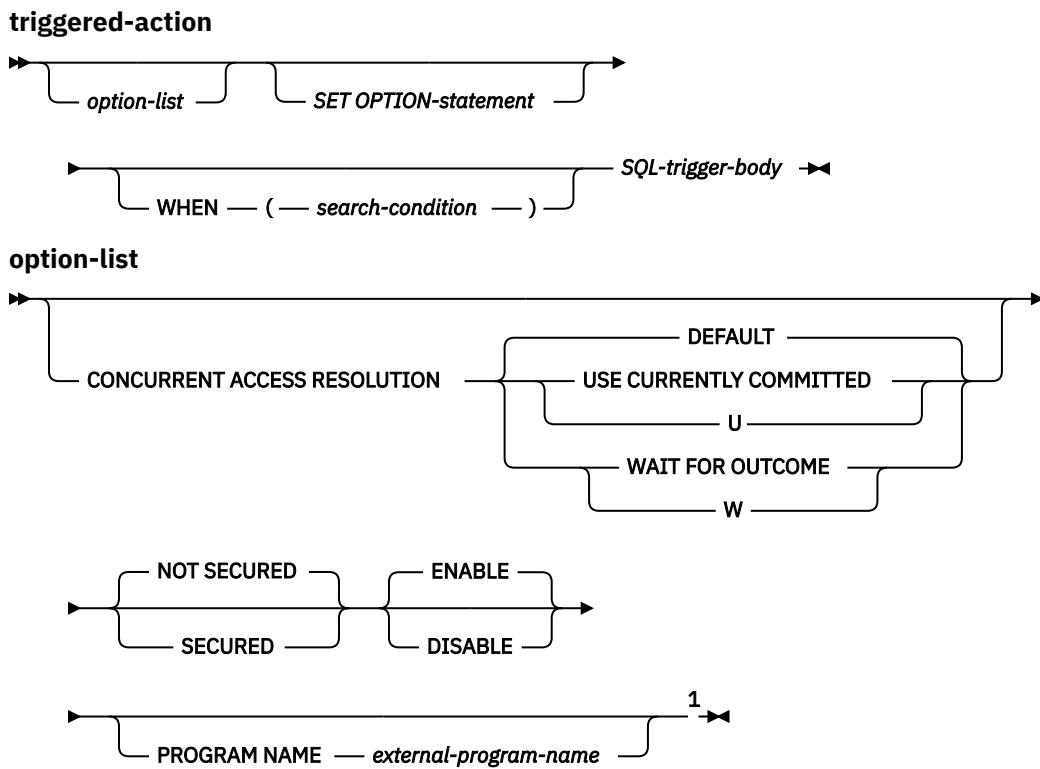

¹ The same clause must not be specified more than once.

trigger-event

Notes:

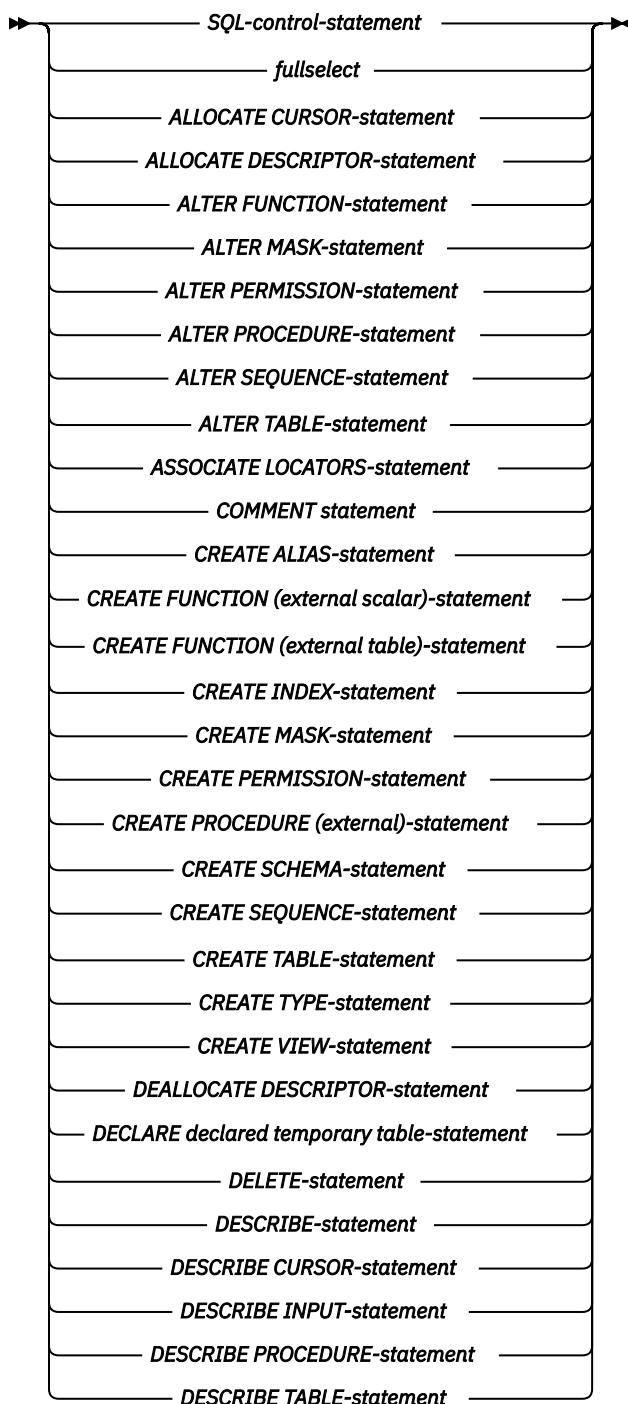

¹ Each *trigger-event* option can be specified only one time.

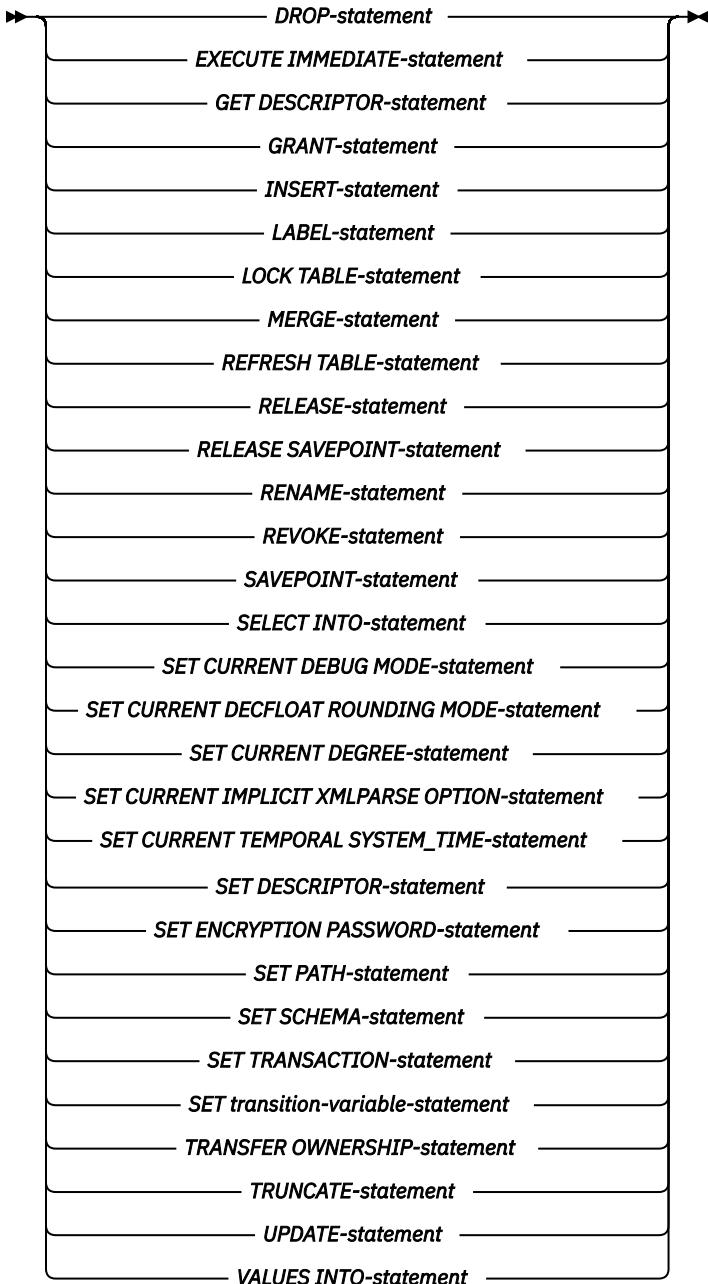

Notes:

¹ The options can be specified in any order. The same clause must not be specified more than once.

SQL-trigger-body

Syntax (continued)

Description

OR REPLACE

Specifies to replace the definition for the trigger if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the trigger are not affected. This option is ignored if a definition for the trigger does not exist at the current server.

trigger-name

Names the trigger. The name, including the implicit or explicit qualifier, must not be the same as a trigger that already exists at the current server. QTEMP cannot be used as the *trigger-name* schema qualifier.

If SQL names were specified, the trigger will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the trigger will be created in the schema that is specified by the qualifier. If not qualified, the trigger will be created in the same schema as the subject table.

If the trigger name is not a valid system name, or if a program with the same name already exists, the database manager will generate a system name. For information about the rules for generating a name, see “[Rules for Table Name Generation](#)” on page 994.

NO CASCADE

NO CASCADE is allowed for compatibility with other products and is ignored by Db2 for i.

BEFORE

Specifies that the trigger is a *before* trigger. The database manager executes the *triggered-action* before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the *triggered-action* does not activate other triggers because the *triggered-action* of a before trigger cannot contain any updates.

BEFORE must not be specified when a *view-name* is specified. FOR EACH STATEMENT must not be specified for a BEFORE trigger.

AFTER

Specifies that the trigger is an *after* trigger. The database manager executes the *triggered-action* after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified when *view-name* is also specified.

INSTEAD OF

Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each kind of operation on a given subject view. The database manager executes the *triggered-action* instead of the insert, delete, or update operation on the subject view.

INSTEAD OF must not be specified when *table-name* is specified. The WHEN clause must not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

trigger-event

Specifies that the triggered action associated with the trigger is to be executed whenever one of the events is applied to the subject table or view. Any combination of the events can be specified, but each event (INSERT, DELETE, UPDATE) can only be specified once.

INSERT

Specifies that the *triggered-action* associated with the trigger is to be executed whenever there is an insert operation on the subject table.

A BEFORE INSERT trigger cannot be added to a history table.

DELETE

Specifies that the *triggered-action* associated with the trigger is to be executed whenever there is a delete operation on the subject table.

A DELETE trigger cannot be added to a table with a referential constraint of ON DELETE CASCADE.

UPDATE

Specifies that the *triggered-action* associated with the trigger is to be executed whenever there is an update operation on the subject table.

An UPDATE trigger event cannot be added to a table with a referential constraint of ON DELETE SET NULL or ON DELETE SET DEFAULT.

A BEFORE UPDATE trigger cannot be added to a history table.

If an explicit *column-name* list is not specified, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the *triggered-action*.

OF *column-name*, ...

Each *column-name* specified must be a column of the subject table, and must appear in the list only once. An update operation on any of the listed columns activates the *triggered-action*. This clause cannot be specified for an INSTEAD OF trigger.

ON *table-name*

Identifies the subject table of a BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server, but must not identify a catalog table, a table in QTEMP, or a declared temporary table.

ON *view-name*

Identifies the subject view of an INSTEAD OF trigger definition. The name must identify a view that exists at the current server, but must not identify a catalog view, or a view in QTEMP. The name must not specify a view that is defined using WITH CHECK OPTION, or a view on which a WITH CHECK OPTION view has been defined, directly or indirectly.

REFERENCING

Specifies the correlation names for the transition tables and the table names for the transition tables. *Correlation-names* identify a specific row in the set of rows affected by the triggering SQL operation. *Table-identifiers* identify the complete set of affected rows.

Each row affected by the triggering SQL operation is available to the *triggered-action* by qualifying columns with *correlation-names* specified as follows:

OLD ROW AS *correlation-name*

Specifies a correlation name that identifies the values in the row prior to the triggering SQL operation. If the trigger event is insert, the value for every column in OLD ROW is the NULL value.

NEW ROW AS *correlation-name*

Specifies a correlation name which identifies the values in the row as modified by the triggering SQL operation and any SET statement in a before trigger that has already executed. If the trigger event is delete, the value for every column in NEW ROW is the NULL value.

The complete set of rows affected by the triggering SQL operation is available to the *triggered-action* by using a temporary table name specified as follows:

OLD TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of affected rows prior to the triggering SQL operation. The OLD TABLE includes the rows that were affected by the trigger if the current activation of the trigger was caused by statements in the *SQL-trigger-body* of a trigger. If the trigger event is insert, the temporary table is empty.

NEW TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the state of the complete set of affected rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed. If the trigger event is delete, the temporary table is empty.

Only one OLD and one NEW *correlation-name* may be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE *table-identifier* may be specified for a trigger. All of the *correlation-names* and *table-identifiers* must be unique from one another.

The OLD *correlation-name* and the OLD_TABLE *table-identifier* are populated only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD *correlation-name* captures the values of the columns in the deleted row, and the OLD_TABLE *table-identifier* captures the values in the set of deleted rows. For an update operation, OLD *correlation-name* captures the values of the columns of a row before the update operation, and the OLD_TABLE *table-identifier* captures the values in the set of updated rows.

The NEW ROW *correlation-name* and the NEW TABLE *table-identifier* are populated only if the triggering event is either an INSERT operation or an UPDATE operation. For both operations, the NEW ROW *correlation-name* captures the values of the columns in the inserted or updated row, and the NEW TABLE *table-identifier* captures the values in the set of inserted or updated rows. For before triggers, the values of the updated rows include the changes from any SET statements in the *triggered-action* of before triggers.

The OLD ROW and NEW ROW *correlation-name* variables cannot be modified in an AFTER trigger or INSTEAD OF trigger.

The tables below summarizes the allowable combinations of correlation variables and transition tables.

Granularity: FOR EACH ROW

MODE	Activation Time	Triggering Operation	Correlation Variables Allowed	Transition Tables Allowed
DB2ROW	BEFORE	DELETE	OLD	NONE
		INSERT	NEW	
		UPDATE	OLD, NEW	
	AFTER or INSTEAD OF	DELETE	OLD	
		INSERT	NEW	
		UPDATE	OLD, NEW	
DB2SQL	BEFORE	DELETE	OLD	OLD TABLE NEW TABLE OLD TABLE, NEW TABLE
		INSERT	NEW	
		UPDATE	OLD, NEW	
	AFTER or INSTEAD OF	DELETE	OLD	
		INSERT	NEW	
		UPDATE	OLD, NEW	

Granularity: FOR EACH STATEMENT

MODE	Activation Time	Triggering Operation	Correlation Variables Allowed	Transition Tables Allowed
DB2SQL	AFTER or INSTEAD OF	DELETE	NONE	OLD TABLE
		INSERT		NEW TABLE
		UPDATE		OLD TABLE, NEW TABLE

A transition variable that has a character data type inherits the CCSID of the column of the subject table. During the execution of the *triggered-action*, the transition variables are treated like variables. Therefore, character conversion might occur.

The temporary transition tables are read-only. They cannot be modified.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

FOR EACH ROW

Specifies that the database manager executes the *triggered-action* for each row of the subject table that the triggering operation modifies. If the triggering operation does not modify any rows, the *triggered-action* is not executed.

FOR EACH STATEMENT

Specifies that the database manager executes the *triggered-action* only once for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is still executed once.

FOR EACH STATEMENT cannot be specified for a BEFORE trigger.

FOR EACH STATEMENT cannot be specified for a MODE DB2ROW trigger.

MODE DB2SQL

MODE DB2SQL is valid for AFTER triggers. MODE DB2SQL AFTER triggers are activated after all of the row operations have occurred.

MODE DB2SQL is only valid for BEFORE triggers if a REFERENCING clause is not specified and the trigger table is not referenced in the *SQL-trigger-body*. MODE DB2SQL BEFORE triggers are activated on each row operation.

MODE DB2ROW

MODE DB2ROW triggers are activated on each row operation.

MODE DB2ROW is valid for both the BEFORE and AFTER activation time.

CONCURRENT ACCESS RESOLUTION

Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

DEFAULT

Specifies that the concurrent access resolution is not explicitly set for this trigger. The value that is in effect when the trigger program is invoked will be used.

WAIT FOR OUTCOME

Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SECURED or NOT SECURED

Specifies whether the trigger is considered secure for row access control and column access control. NOT SECURED is the default.

SECURED

Specifies that the trigger is considered secure for row access control and column access control.

SECURED must be specified for a trigger whose subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies that the trigger is considered not secure for row access control and column access control.

NOT SECURED must not be specified explicitly or implicitly for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

ENABLE or DISABLE

Specifies the state for the trigger. ENABLE is the default.

ENABLE

The trigger will be fired during the appropriate data change operations.

DISABLE

The trigger will not be fired during the appropriate data change operations.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the trigger. A CREATE TRIGGER statement can be encoded using the WRAP scalar function.

PROGRAM NAME *external-program-name*

Specifies the unqualified name of the program to be created for the trigger. *external-program-name* must be in the form of a program name. It must not be a service program name.

triggered-action

Specifies the action to be performed when a trigger is activated. The *triggered-action* is composed of one or more SQL statements and by an optional condition that controls whether the statements are executed.

SET OPTION-statement

Specifies the options that will be used to create the trigger. For example, to create a debuggable trigger, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

The default values for the options depend on the options in effect at create time. For more information, see “[SET OPTION](#)” on page 1303.

The options CNULIGN, CNULRQD, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE TRIGGER statement. The COMMIT option is allowed, but ignored.

The options DATFMT, DATSEP, TIMFMT, and TIMSEP cannot be used if OLD ROW or NEW ROW is specified.

WHEN (search-condition)

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the *search-condition* evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

A WHEN clause must not be specified with an INSTEAD OF trigger.

SQL-trigger-body

Specifies a single *SQL-procedure-statement*, including a compound statement. See “[SQL control statements](#)” on page 1359 for more information about defining SQL triggers using the SQL Procedural Language (SQL PL).

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, SET TRANSACTION, and SET RESULT SETS statement is not allowed in the *triggered-action* of a trigger.

An UNDO handler is not allowed in a trigger.

All tables, views, aliases, distinct types, global variables, user-defined functions, and procedures referenced in the *triggered-action* must exist at the current server when the trigger is created. The table or view that an alias refers to must also exist when the trigger is created. This includes objects in library QTEMP. While objects in QTEMP can be referenced in the *triggered-action*, dropping those objects in QTEMP will not cause the trigger to be dropped.

All transition variable names are column names of the subject table. System column names of the subject table cannot be used as transition variable names.

The triggered action of a BEFORE trigger on a column of type XML can invoke the XMLVALIDATE function through a SET statement, leave values of type XML unchanged, or assign them to NULL using a SET statement.

A dynamic statement in the *triggered-action* can use 3-part names to access a remote server. A library with the same name as the trigger program's library must exist on the remote server. Static statements in the *triggered-action* cannot use 3-part names.

Static and dynamic statements in the *triggered-action* can invoke a procedure or a user-defined function that can access a server other than the current server if the procedure or user-defined function runs in a different activation group.

Notes

Trigger ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the trigger is created exists, the *owner* of the trigger is that user profile.
- Otherwise, the *owner* of the trigger is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the trigger is the user profile or group user profile of the thread executing the statement.

Trigger authority: The trigger program object authorities are:

- When SQL naming is in effect, the trigger program will be created with the public authority of *EXCLUDE, and adopt authority from the schema qualifier of the trigger-name if a user profile with that name exists. If a user profile for the schema qualifier does exist, then the owner of the trigger program will be the user profile for the schema qualifier. Note that the special authorities *ALLOBJ and *SECADM are required to create the trigger program object in the schema qualifier library if a user profile exists that has the same name as the schema qualifier, and the name is different from the authorization ID of the statement. If a user profile for the schema qualifier does not exist, then the owner of the trigger program will be the user profile or group user profile of the thread executing the SQL CREATE TRIGGER statement. The group user profile will be the owner of the trigger program object, only if OWNER(*GRPPRF) was specified on the user's profile who is executing the statement. If the owner of the trigger program is a member of a group profile, and if OWNER(*GRPPRF) was specified on the user's profile, the program will run with the adopted authority of the group profile.
 - For an INSTEAD OF TRIGGER, the privilege associated with the trigger event will be granted to the owner of the view and to the user profile or group user profile of the thread executing the CREATE TRIGGER statement.
- When System naming is in effect, the trigger program will be created with public authority of *EXCLUDE, and adopt authority from the user or group user profile of the thread executing the SQL CREATE TRIGGER statement.

Execution authorization: The user executing the triggering SQL operation does not need authority to execute a static *triggered-SQL-statement*. A static *triggered-SQL-statement* will execute using the authority of the *owner* of the trigger.

REPLACE rules: When a trigger is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.
- The firing order of the trigger is not maintained.

Activating a trigger: Only insert, delete, or update operations can activate a trigger. A delete operation that occurs as a result of a referential constraint will not activate a trigger. Hence,

- A trigger with a DELETE trigger event cannot be added to a table with a referential constraint of ON DELETE CASCADE.
- A trigger with an UPDATE trigger event cannot be added to a table with a referential constraint of ON DELETE SET NULL or ON DELETE SET DEFAULT.

The activation of a trigger may cause *trigger cascading*. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions may also cause updates as a result of the original modification, which may result in the activation of additional triggers. With trigger cascading, a significant chain of triggers may be activated causing significant change to the database as a result of a single delete, insert or update statement. The number of levels of cascading is limited to 200 or the maximum amount of storage allowed in the job or process, whichever comes first.

Adding triggers to enforce constraints: Adding a trigger to a table that already has rows in it will not cause the triggered actions to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Considerations for implicitly hidden columns: In the body of a trigger, a trigger transition variable that corresponds to an implicitly hidden column can be referenced. A trigger transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table.

Likewise, a trigger transition variable will exist for the column that is defined as implicitly hidden. A trigger transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

Read-only views: The addition of an INSTEAD OF trigger for a view affects the read-only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

Transition variable values and INSTEAD OF triggers: All trigger transition variables in an INSTEAD OF trigger are nullable.

The initial values for new transition variables or new transition table columns visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the INSERT statement, the corresponding new transition variable or new transition table column is that explicitly specified value.
- If a value is not explicitly specified for a column in the INSERT statement or the DEFAULT keyword is specified, the corresponding new transition variable or new transition table column is:
 - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger) and not based on a generated column or ROWID,
 - otherwise, the null value.

The initial values for new transition variables or new transition table columns visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the UPDATE statement, the corresponding new transition variable or new transition table column is that explicitly specified value.
- If the DEFAULT keyword is explicitly specified for a column in the UPDATE statement, the corresponding new transition variable or new transition table column is:
 - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger) and not based on a generated column or ROWID,
 - otherwise, the null value.
- Otherwise, the corresponding new transition variable or new transition table column is the existing value of the column in the row.

Obfuscated statements: A CREATE TRIGGER statement can be executed in obfuscated form. In an obfuscated statement, only the trigger name is readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the trigger is created from an obfuscated statement are ignored.

A trigger that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported. Consequently, a table with a trigger created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Creating a trigger with the SECURED option: The trigger is considered secure after the CREATE TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, a user that has security administrator authority needs to ensure that those

functions are allowed to access that data and that an audit procedure is in place for those functions, and that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control activated.

Creating a trigger with the NOT SECURED option: The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if its subject table is a view and one or more of the underlying tables in the view is using row access control or column access control.

Transition variable values and row and column access control: Row and column access control is not enforced for transition variables and transition tables. If row or column access control is enforced for the triggering table, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for transition variables and transition tables that are referenced in the trigger body or are passed as arguments to user-defined functions invoked within the trigger body. To ensure there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables, the trigger must be created with the SECURED option. If the trigger is not secure, row access control and column access control cannot be enforced for the triggering table and the CREATE TRIGGER statement returns an error.

Multiple triggers: Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated based on the mode and the order in which they were created:

- MODE DB2ROW triggers (and native triggers created via the ADDPFTRG CL command) are fired first in the order in which they were created
- MODE DB2SQL triggers are fired next in the order in which they were created

For example, a MODE DB2ROW trigger that was created first is executed first, the MODE DB2ROW trigger that was created second is executed second.

A maximum of 300 triggers can be added to any given source table.

When a trigger is recreated using REPLACE, its position in the activation order is not maintained. It behaves as if the trigger were dropped and created again.

Adding columns to a subject table or a table referenced in the triggered action: If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an UPDATE trigger that was defined without an explicit column list, then an update to the new column will cause the activation of the trigger.
- If the SQL statements in the *triggered-action* refer to the triggering table, the new column is not accessible to the SQL statements until the trigger is recreated.
- The OLD_TABLE and NEW_TABLE transition tables will contain the new column, but the column cannot be referenced unless the trigger is recreated.

If a column is added to any table referenced by the SQL statements in the triggered-action, the new column is not accessible to the SQL statements until the trigger is recreated.

Dropping or revoking privileges on a table referenced in the triggered action: If an object such as a table, view or alias, referenced in the *triggered-action* is dropped, the access plans of the statements that reference the object will be rebuilt when the trigger is fired. If the object does not exist at that time, the corresponding INSERT, UPDATE or DELETE operation on the subject table will fail.

If a privilege that the creator of the trigger is required to have for the trigger to execute is revoked, the access plans of the statements that reference the object will be rebuilt when the trigger is fired. If the appropriate privilege does not exist at that time, the corresponding INSERT, UPDATE or DELETE operation on the subject table will fail.

Errors executing triggers: If a SIGNAL statement is executed in the *SQL-trigger-body*, an SQLCODE -438 and the SQLSTATE specified in the SIGNAL statement will be returned.

Other errors that occur during the execution of *SQL-trigger-body* statements are returned using SQLSTATE 09000 and SQLCODE -723.

Special registers in triggers: The values of the special registers are saved before a trigger is activated and are restored on return from the trigger. The values of the special registers are inherited from the triggering SQL operation.

Transaction isolation: All triggers, when they are activated, perform a SET TRANSACTION statement unless the isolation level of the application program invoking the trigger is the same as the default isolation level of the trigger program. This is necessary so that all of the operations by the trigger are performed with the same isolation level as the application program that caused the trigger to be run. The user may put their own SET TRANSACTION statements in an *SQL-control-statement* in the *SQL-trigger-body* of the trigger. If the user places a SET TRANSACTION statement within the *SQL-trigger-body* of the trigger, then the trigger will run with the isolation level specified in the SET TRANSACTION statement, instead of the isolation level of the application program that caused the trigger to be run.

If the application program that caused a trigger to be activated, is running with an isolation level other than No Commit (COMMIT(*NONE) or COMMIT(*NC)), the operations within the trigger will be run under commitment control and will not be committed or rolled back until the application commits its current unit of work. If ATOMIC is specified in the *SQL-trigger-body* of the trigger, and the application program that caused the ATOMIC trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), the operations within the trigger will not be run under commitment control. If the application that caused the trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), then the operations of a trigger are written to the database immediately, and cannot be rolled back.

If both system triggers defined by the Add Physical File Trigger (ADDPFTRG) CL command and SQL triggers defined by the CREATE TRIGGER statement are defined for a table, it is recommended that the system triggers perform a SET TRANSACTION statement so that they are run with the same isolation level as the original application that caused the triggers to be activated. It is also recommended that the system triggers run in the Activation Group of the calling application. If system triggers run in a separate Activation Group (ACTGRP(*NEW)), then those system triggers will not participate in the unit of the work for the calling application, nor in the unit of work for any SQL triggers. System triggers that run in a separate Activation Group are responsible for committing or rolling back any database operations they perform under commitment control. Note that SQL triggers defined by the CREATE TRIGGER statement always run in the caller's Activation Group.

If the triggering application is running with commitment control, the operations of an SQL trigger, and any cascaded SQL triggers, will be captured into a sub-unit of work. If the operations of the trigger and any cascaded triggers are successful, the operations captured in the sub-unit of work will be committed or rolled back when the triggering application commits or rolls back its current unit of work. Any system triggers that run in the same Activation Group as the caller, and perform a SET TRANSACTION to the isolation level of the caller, will also participate in the sub-unit of work. If the triggering application is running without commit control, then the operations of the SQL triggers will also be run without commitment control.

If an application that causes a trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), and it issues an INSERT, UPDATE, or DELETE statement that encounters an error during the execution of the statement, no other system or SQL triggers will be activated following the error for that operation. However, some number of changes will already have been performed. If the triggering application is running with commitment control, the operations of any triggers that are captured in a sub-unit of work will be rolled back when the first error is encountered, and no additional triggers will be activated for the current INSERT, UPDATE, or DELETE statement.

Performance considerations: Create the trigger under the isolation level that will most often be used by the application programs that cause the trigger to fire. The SET OPTION statement can be used to explicitly choose the isolation level.

ROW triggers (especially MODE DB2ROW triggers) perform much better than TABLE level triggers.

Considerations for implicitly hidden columns: A transition variable will exist for any column defined as implicitly hidden. In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced.

Triggered actions in the catalog: At the time the trigger is created, the *triggered-action* is modified as a result of the CREATE TRIGGER statement:

- Naming mode is switched to SQL naming.
- All unqualified object references are explicitly qualified
- All implicit column lists (for example, SELECT *, INSERT with no column list, UPDATE SET ROW) are expanded to be the list of actual column names.

The modified *triggered-action* is stored in the catalog.

Renaming or moving a table referenced in the triggered action: Any table (including the subject table) referenced in a *triggered-action* can be moved or renamed. However, the *triggered-action* will continue to reference the old name or schema. An error will occur if the referenced table is not found when the *triggered-action* is executed. Hence, you should drop the trigger and then re-create the trigger so that it refers to the renamed or moved table.

Datetime considerations: If OLD ROW or NEW ROW is specified, the date or time constants and the string representation of dates and times in variables that are used in SQL statements in the *triggered-action* must have a format of ISO, EUR, JIS, USA, or must match the date and time formats specified when the table was created if it was created using DDS and the CRTPF CL command. If the DDS specifications contain multiple different date or time formats, the trigger cannot be created.

Operations that invalidate triggers: An *inoperative trigger* is a trigger that is no longer available to be activated. If a trigger becomes invalid, no INSERT, UPDATE, or DELETE operations will be allowed on the subject table or view. A trigger becomes invalid if:

- The SQL statements in the *triggered-action* reference the subject table or view, the trigger is a self-referencing trigger, and the table or view is duplicated using the system CRTDUOBJ CL command, or
- The SQL statements in the *triggered-action* reference tables or views in the from library and the objects are not found in the new library when the table or view is duplicated using the system CRTDUOBJ CL command, or
- The table or view is restored to a new library using the system RSTOBJ or RSTLIB CL commands, and the *triggered-action* references the subject table or subject view, the trigger is a self-referencing trigger.

An invalid trigger must first be dropped before it can be recreated by issuing a CREATE TRIGGER statement. Note that dropping and recreating a trigger will affect the activation order of a trigger if multiple triggers for the same triggering operation and activation time are defined for the subject table.

Trigger program object: When a trigger is created, SQL creates a temporary source file that will contain C source code with embedded SQL statements. A program object is then created using the CRTPGM command. The SQL options used to create the program are the options that are in effect at the time the CREATE TRIGGER statement is executed. The program is created with ACTGRP(*CALLER).

The program is created with STGMDL(*SNGLVL). If the trigger runs on behalf of an application that uses STGMDL(*TERASPACE) and also uses commitment control, the entire application will need to run under a job scoped commitment definition (STRCMTCTL CMTSCOPE(*JOB)).

The trigger will execute with the adopted authority of the *owner* of the trigger.

Examples

Example 1: Create two triggers that track the number of employees that a company manages. The triggering table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The COMPANY_STATS table has the following properties:

```
CREATE TABLE COMPANY_STATS  
  (NBEMP INTEGER,
```

```
NBPRODUCT INTEGER,  
REVENUE DECIMAL(15,0))
```

This example uses row triggers to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER NEW_HIRE  
AFTER INSERT ON EMPLOYEE  
FOR EACH ROW MODE DB2SQL  
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER FORM_EMP  
AFTER DELETE ON EMPLOYEE  
FOR EACH ROW MODE DB2SQL  
BEGIN ATOMIC  
    UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;  
END
```

Example 2: Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity. The function eliminates any duplicate requests to order the same PARTNO and sends the unique order to the appropriate supplier.

This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER  
AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS  
REFERENCING NEW_TABLE AS NTABLE  
FOR EACH STATEMENT MODE DB2SQL  
BEGIN ATOMIC  
    DECLARE REQUEST_VAR INT;  
    SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)  
    INTO REQUEST_VAR  
    FROM NTABLE  
    WHERE ON_HAND < 0.10 * MAX_STOCKED;  
END
```

Example 3: Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of 75001 and a description. This example shows that the SIGNAL SQLSTATE statement is useful for restricting changes that violate business rules.

```
CREATE TRIGGER SAL_ADJ  
AFTER UPDATE OF SALARY ON EMPLOYEE  
REFERENCING OLD AS OLD_EMP  
        NEW AS NEW_EMP  
FOR EACH ROW MODE DB2SQL  
WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY *1.20))  
BEGIN ATOMIC  
    SIGNAL SQLSTATE '75001'('Invalid Salary Increase - Exceeds 20%');  
END
```

CREATE TYPE

The CREATE TYPE statement defines a user-defined data type at the current server.

The following types of user-defined data types can be defined:

- **Array**

A user-defined data type that is an ordinary array. The elements of an array type are based on one of the built-in data types. See “[CREATE TYPE \(array\)](#)” on page 1013.

- **Distinct**

A user-defined data type that shares a common representation with one of the built-in data types. It can be defined to use strong type rules or weak type rules. Functions that cast between the user-defined distinct type and the source built-in data type are generated when a strongly typed distinct type is created. See “[CREATE TYPE \(distinct\)](#)” on page 1017.

CREATE TYPE (array)

The CREATE TYPE (array) statement defines an array type at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSTYPES catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the array type is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

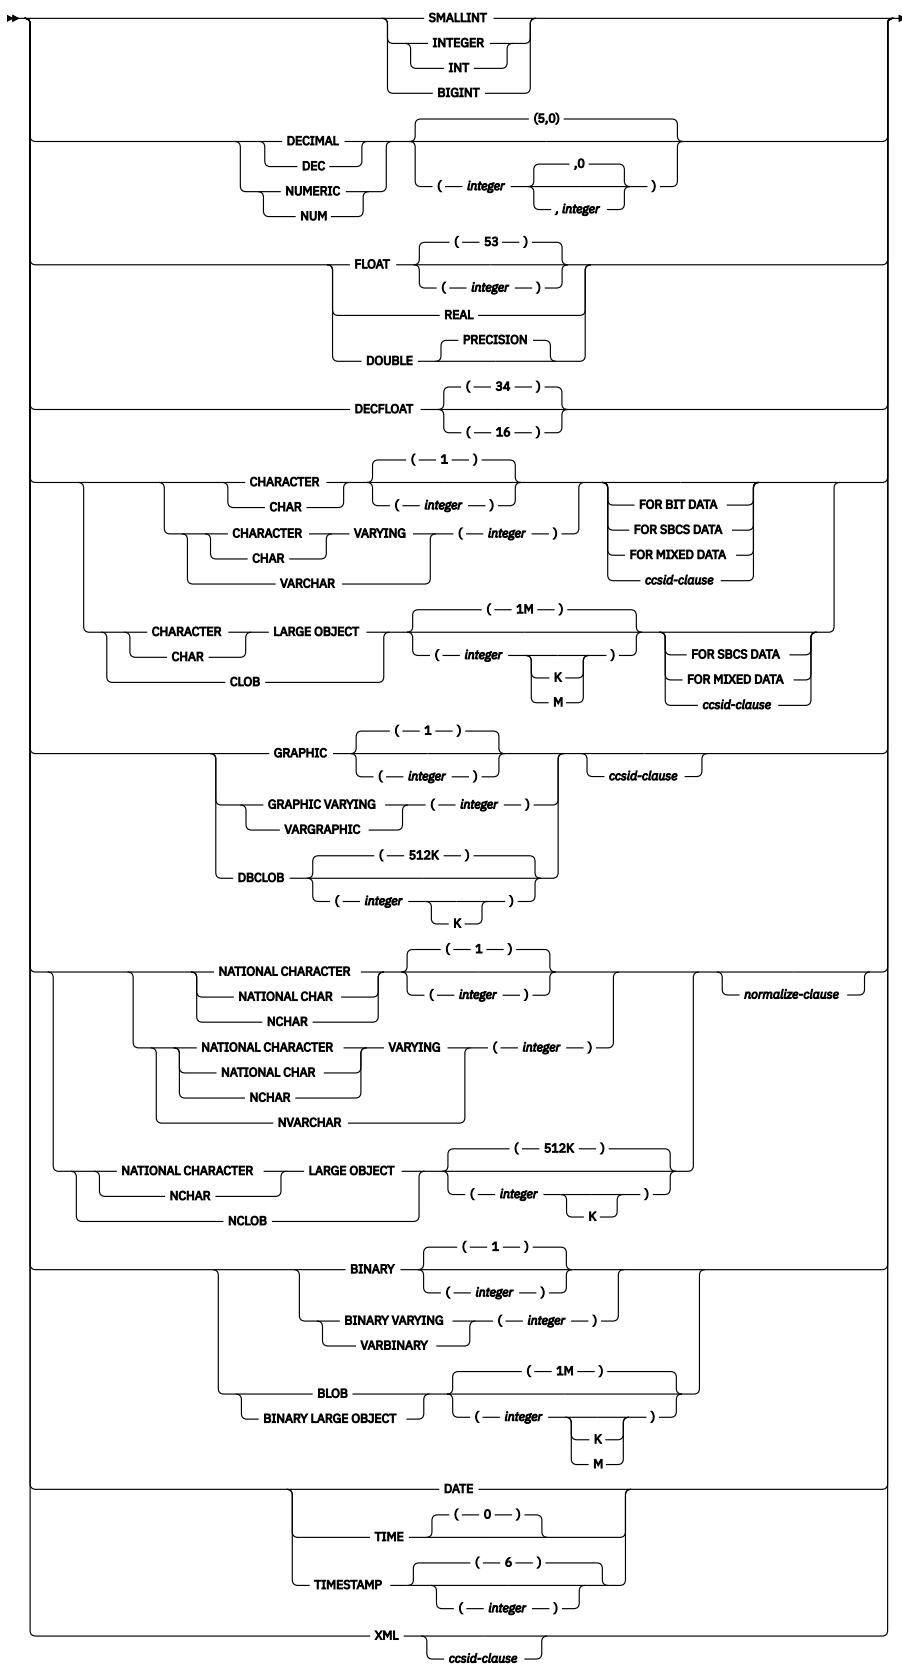

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

►► CREATE — TYPE — *array-type-name* — AS — *built-in-type* →

built-in-type

ccsid-clause

► CCSID — *integer* —►

normalize-clause

normalize-clause

Description

array-type-name

Names the array. The name, including the implicit or explicit qualifier, must not be the same as a distinct type or array type that already exists at the current server.

If SQL names were specified, the array type will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the array type will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the array type will be created in the current library (*CURLIB).
- Otherwise, the array type will be created in the current schema.

If the array type name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see [“Rules for Table Name Generation” on page 994](#).

array-type-name must not be the name of a built-in data type, or any of the following system-reserved keywords even if you specify them as delimited identifiers.

=	<	>	>=
<=	<>	=	<
=<	!=	<!	!>
ALL	FALSE	POSITION	XMLAGG
AND	FOR	RID	XMLATTRIBUTES
ANY	FROM	RRN	XMLCOMMENT
ARRAY_AGG	HASHED_VALUE	SELECT	XMLCONCAT
BETWEEN	IN	SIMILAR	XMLDOCUMENT
BOOLEAN	INTERVAL	SOME	XMLELEMENT
CASE	IS	STRIP	XMLFOREST
CAST	LIKE	SUBSTRING	XMLGROUP
CHECK	MATCH	TABLE	XMLNAMESPACES
DATAPARTITIONNAME	NODENAME	THEN	XMLPARSE
DATAPARTITIONNUM	NODENUMBER	TRIM	XMLPI
DBPARTITIONNAME	NOT	TRUE	XMLROW
DBPARTITIONNUM	NULL	TYPE	XMLSERIALIZE
DISTINCT	ONLY	UNIQUE	XMLTEXT
EXCEPT	OR	UNKNOWN	XMLVALIDATE
EXISTS	OVERLAPS	WHEN	XSLTRANSFORM
EXTRACT	PARTITION		

If a qualified *array-type-name* is specified, the schema name cannot be QSYS, QSYS2, QTTEMP, or SYSIBM.

built-in-type

Specifies the built-in data type used as the data type for all the elements of the array. See “[CREATE TABLE](#)” on page 945 for a more complete description of each built-in data type.

If a specific value is not specified for the data types that have length, precision, or scale attributes, the default attributes of the data type as shown in the syntax diagram are implied.

If the array type is for a string data type, a CCSID is associated with the array type at the time the array type is created. For more information about data types, see “[CREATE TABLE](#)” on page 945.

ARRAY [integer-constant]

Specifies that the array has a maximum cardinality of *integer-constant*. The value must be a positive number greater than 0. If no value is specified, the maximum integer value of 2147483647 is used. The maximum number of array elements that can be assigned in the array is the number of elements that fit in 4 gigabytes. Each varying length, LOB, and XML array element is allocated as its maximum length.

Notes

Additional generated functions: Functions are created to convert to and from the array type, but service programs are not created, so you cannot grant or revoke privileges to these functions.

Names of the generated cast functions: The unqualified name of one of the cast functions ARRAY. The name of the cast function that converts to the array type is the name of the array type. The input parameter of the cast function has the same data type as the ARRAY.

For example, assume that an array type named T_SHOESIZES is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZES AS INT ARRAY[]
```

When the statement is executed, the database manager also generates the following cast functions. ARRAY converts from the array type to an array, and T_SHOESIZES converts from an array to the array type.

A generated cast function cannot be explicitly dropped. The cast functions that are generated for an array type are implicitly dropped when the array type is dropped with the DROP statement.

Array type attributes: An array type is created as a *SQLUDT object.

Array type ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the array type is created exists, the *owner* of the array type is that user profile.
- Otherwise, the *owner* of the array type is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the array type is the user profile or group user profile of the thread executing the statement.

Array type authority: If SQL names are used, array types are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, array types are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the array type is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the array type.

Examples

Example 1: Create an array type named PHONENUMBERS with a maximum of 5 elements that are of the DECIMAL(10,0) data type.

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[5]
```

Example 2: Create an array type named NUMBERS in the schema GENERIC for which the maximum number of elements is not known.

```
CREATE TYPE GENERIC.NUMBERS  
AS BIGINT ARRAY[]
```

CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type at the current server. A distinct type is always sourced on one of the built-in data types and can be defined to use strong type or weak type rules.

Successful execution of the statement for strong type rules also generates:

- A function to cast from the distinct type to its source type
- A function to cast from the source type to its distinct type
- As appropriate, support for the use of comparison operators with the distinct type.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSTYPES catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

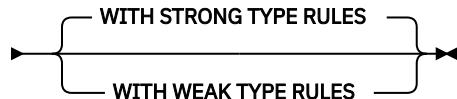

If SQL names are specified and a user profile exists that has the same name as the library into which the distinct type is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

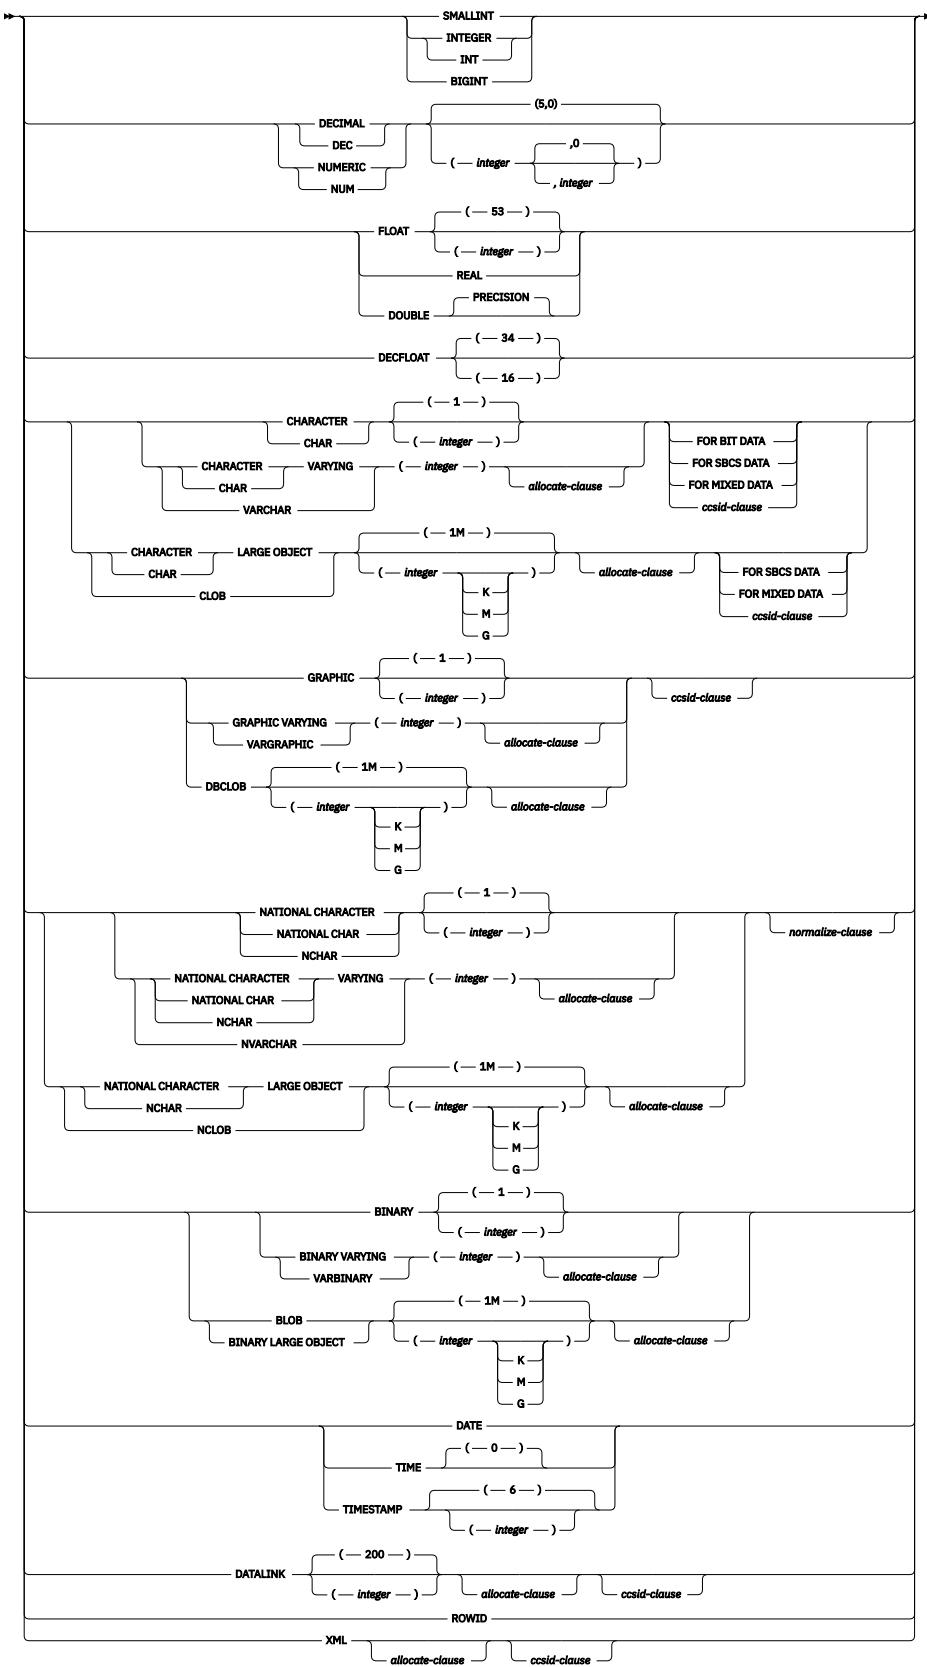

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

built-in-type

ccsid-clause

►► CCSID — *integer* —►►
 —►► *normalize-clause* —►►

normalize-clause

Description

distinct-type-name

Names the distinct type. The name, including the implicit or explicit qualifier, must not be the same as a distinct type or array type that already exists at the current server.

If SQL names were specified, the distinct type will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the distinct type will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the distinct type will be created in the current library (*CURLIB).
- Otherwise, the distinct type will be created in the current schema.

If the distinct type name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see [“Rules for Table Name Generation” on page 994](#).

distinct-type-name must not be the name of a built-in data type, or any of the following system-reserved keywords even if you specify them as delimited identifiers.

=	<	>	>=
<=	<>	=	<
=<	!=	<!	>
ALL	FALSE	POSITION	XMLAGG
AND	FOR	RID	XMLATTRIBUTES
ANY	FROM	RRN	XMLCOMMENT
ARRAY_AGG	HASHED_VALUE	SELECT	XMLCONCAT
BETWEEN	IN	SIMILAR	XMLDOCUMENT
BOOLEAN	INTERVAL	SOME	XMLELEMENT
CASE	IS	STRIP	XMLFOREST
CAST	LIKE	SUBSTRING	XMLGROUP
CHECK	MATCH	TABLE	XMLNAMESPACES
DATAPARTITIONNAME	NODENAME	THEN	XMLPARSE
DATAPARTITIONNUM	NODENUMBER	TRIM	XMLPI
DBPARTITIONNAME	NOT	TRUE	XMLROW
DBPARTITIONNUM	NULL	TYPE	XMLSERIALIZE
DISTINCT	ONLY	UNIQUE	XMLTEXT
EXCEPT	OR	UNKNOWN	XMLVALIDATE
EXISTS	OVERLAPS	WHEN	XSLTRANSFORM
EXTRACT	PARTITION		

If a qualified *distinct-type-name* is specified, the schema name cannot be QSYS, QSYS2, QTEMP, or SYSIBM.

built-in-type

Specifies the built-in data type used as the basis for the internal representation of the distinct type. See [“CREATE TABLE” on page 945](#) for a more complete description of each built-in data type.

For portability of applications across platforms, use the following recommended data type names:

- DOUBLE or REAL instead of FLOAT.
- DECIMAL instead of NUMERIC.

If a specific value is not specified for the data types that have length, precision, or scale attributes, the default attributes of the data type as shown in the syntax diagram are implied.

If the distinct type is sourced on a string data type, a CCSID is associated with the distinct data type at the time the distinct type is created. For more information about data types, see [“CREATE TABLE” on page 945](#).

WITH STRONG TYPE RULES

Specifies that strong typing rules are used for operations where this data type is an operand including assignments and comparisons. This is the default.

WITH WEAK TYPE RULES

Specifies that weak typing rules are used for operations where this data type is an operand including assignments, comparisons, and function resolution. When values of a weakly typed distinct type are used, the data type is effectively treated as the specified *built-in-type* when processing the operation.

Notes

Additional generated functions: When a strongly typed distinct type is created, the following functions are generated to convert to and from the source type:

- The distinct type to the source type
- The source type to the distinct type
- INTEGER to the distinct type if the source type is SMALLINT
- DOUBLE to the distinct type if the source type is REAL
- VARCHAR to the distinct type if the source type is CHAR
- VARGRAPHIC to the distinct type if the source type is GRAPHIC

These functions are created as if the following statements were executed (except that the service programs are not created, so you cannot grant or revoke privileges to these functions):

```
CREATE FUNCTION source-type-name (distinct-type-name)
    RETURNS source-type-name
```

```
CREATE FUNCTION distinct-type-name (source-type-name)
    RETURNS distinct-type-name
```

Names of the generated cast functions: [Table 96 on page 1021](#) contains details about the generated cast functions for strongly typed distinct types. The unqualified name of the cast function that converts from the distinct type to the source type is the name of the source data type.

In cases in which a length, precision, or scale is specified for the source data type in the CREATE TYPE statement, the unqualified name of the cast function that converts from the distinct type to the source type is simply the name of the source data type. The data type of the value that the cast function returns includes any length, precision, or scale values that were specified for the source data type on the CREATE TYPE statement.

The name of the cast function that converts from the source type to the distinct type is the name of the distinct type. The input parameter of the cast function has the same data type as the source data type, including the length, precision, and scale.

The cast functions that are generated are created in the same schema as that of the distinct type. A function with the same name and same function signature must not already exist in the current server.

For example, assume that a distinct type named T_SHOESIZE is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS VARCHAR(2) WITH COMPARISONS
```

When the statement is executed, the database manager also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS VARCHAR(2)  
FUNCTION CLAIRE.T_SHOESIZE (VARCHAR(2) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T_SHOESIZE has an input parameter with a data type of VARCHAR(2).

A generated cast function cannot be explicitly dropped. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the source data type for a strongly typed distinct type, the following table gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

Table 96. CAST Functions on Strongly Typed Distinct Types

Source Type Name	Function Name	Parameter Type	Return Type
SMALLINT	<i>distinct-type-name</i>	SMALLINT	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	INTEGER	<i>distinct-type-name</i>
INTEGER	<i>distinct-type-name</i>	SMALLINT	SMALLINT
	<i>distinct-type-name</i>	INTEGER	<i>distinct-type-name</i>
BIGINT	<i>distinct-type-name</i>	INTEGER	INTEGER
	<i>distinct-type-name</i>	BIGINT	<i>distinct-type-name</i>
DECIMAL	<i>distinct-type-name</i>	BIGINT	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC	<i>distinct-type-name</i>	DECIMAL	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	NUMERIC(p,s)	NUMERIC(p,s)
REAL or FLOAT(n) where n <= 24	<i>distinct-type-name</i>	NUMERIC	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	REAL	<i>distinct-type-name</i>
DOUBLE or DOUBLE PRECISION or FLOAT(n) where n > 24	<i>distinct-type-name</i>	REAL	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
DECFLOAT	<i>distinct-type-name</i>	DOUBLE	DECFLOAT
	<i>distinct-type-name</i>	DECFLOAT	DECFLOAT
CHAR	<i>distinct-type-name</i>	DECFLOAT	DECFLOAT
	<i>distinct-type-name</i>	CHAR(n)	<i>distinct-type-name</i>
CHAR	<i>distinct-type-name</i>	CHAR	CHAR(n)
	<i>distinct-type-name</i>	CHAR(n)	<i>distinct-type-name</i>

Table 96. CAST Functions on Strongly Typed Distinct Types (continued)

Source Type Name	Function Name	Parameter Type	Return Type
	<i>distinct-type-name</i>	VARCHAR(n)	<i>distinct-type-name</i>
VARCHAR	<i>distinct-type-name</i>	VARCHAR(n)	<i>distinct-type-name</i>
	VARCHAR	<i>distinct-type-name</i>	VARCHAR(n)
CLOB	<i>distinct-type-name</i>	CLOB(n)	<i>distinct-type-name</i>
	CLOB	<i>distinct-type-name</i>	CLOB(n)
GRAPHIC	<i>distinct-type-name</i>	GRAPHIC(n)	<i>distinct-type-name</i>
	GRAPHIC	<i>distinct-type-name</i>	GRAPHIC(n)
	<i>distinct-type-name</i>	VARGRAPHIC(n)	<i>distinct-type-name</i>
VARGRAPHIC	<i>distinct-type-name</i>	VARGRAPHIC(n)	<i>distinct-type-name</i>
	VARGRAPHIC	<i>distinct-type-name</i>	VARGRAPHIC(n)
DBCLOB	<i>distinct-type-name</i>	DBCLOB(n)	<i>distinct-type-name</i>
	DBCLOB	<i>distinct-type-name</i>	DBCLOB(n)
BINARY	<i>distinct-type-name</i>	BINARY(n)	<i>distinct-type-name</i>
	BINARY	<i>distinct-type-name</i>	BINARY(n)
	<i>distinct-type-name</i>	VARBINARY(n)	<i>distinct-type-name</i>
VARBINARY	<i>distinct-type-name</i>	VARBINARY(n)	<i>distinct-type-name</i>
	VARBINARY	<i>distinct-type-name</i>	VARBINARY(n)
BLOB	<i>distinct-type-name</i>	BLOB(n)	<i>distinct-type-name</i>
	BLOB	<i>distinct-type-name</i>	BLOB(n)
DATE	<i>distinct-type-name</i>	DATE	<i>distinct-type-name</i>
	DATE	<i>distinct-type-name</i>	DATE
TIME	<i>distinct-type-name</i>	TIME	<i>distinct-type-name</i>
	TIME	<i>distinct-type-name</i>	TIME
TIMESTAMP	<i>distinct-type-name</i>	TIMESTAMP(p)	<i>distinct-type-name</i>
	TIMESTAMP	<i>distinct-type-name</i>	TIMESTAMP(p)
DATALINK	<i>distinct-type-name</i>	DATALINK	<i>distinct-type-name</i>
	DATALINK	<i>distinct-type-name</i>	DATALINK
ROWID	<i>distinct-type-name</i>	ROWID	<i>distinct-type-name</i>
	ROWID	<i>distinct-type-name</i>	ROWID

NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. DECIMAL and DOUBLE should be used instead.

Built-in functions: The functions described in the above table are the only functions that are generated automatically when a strongly typed distinct type is defined. Consequently, none of the built-in functions (AVG, MAX, LENGTH, and so on) are automatically supported for the strongly typed distinct type. A built-in function can be used on a strongly typed distinct type only after a sourced user-defined function, which

is based on the built-in function, has been created for the distinct type. See “[Extending or overriding a built-in function](#)” on page 815.

The schema name of the distinct type must be included in the distinct type for successful use of these operators and cast functions in SQL statements.

Distinct type attributes: A distinct type is created as a *SQLUDT object.

Distinct type ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the distinct type is created exists, the *owner* of the distinct type is that user profile.
- Otherwise, the *owner* of the distinct type is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the distinct type is the user profile or group user profile of the thread executing the statement.

Distinct type authority: If SQL names are used, distinct types are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, distinct types are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the distinct type is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the distinct type.

Syntax alternatives: The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement if WITH WEAK TYPE RULES is not specified. Use WITH COMPARISONS only if it is required for compatibility with other products in the Db2 family.

For compatibility with previous versions of Db2:

- CREATE DISTINCT TYPE can be specified in place of CREATE TYPE.

Examples

Example 1: Create a strongly typed distinct type named SHOESIZE that is sourced on the built-in INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER WITH COMPARISONS
```

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

Example 2: Create a strongly typed distinct type named MILES that is sourced on the built-in DOUBLE data type.

```
CREATE TYPE MILES  
AS DOUBLE
```

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.

Example 3: Create a strongly typed distinct type T_DEPARTMENT that is sourced on the built-in CHAR data type.

```
CREATE TYPE CLAIRE.T_DEPARTMENT AS CHAR(3)
```

The successful execution of this statement also generates three cast functions:

- Function CLAIRE.CHAR takes a T_DEPARTMENT as input and returns a value with data type CHAR(3).
- Function CLAIRE.T_DEPARTMENT takes a CHAR(3) as input and returns a value with distinct type T_DEPARTMENT.

- Function CLAIRE.T_DEPARTMENT takes a VARCHAR(3) as input and returns a value with distinct type T_DEPARTMENT.

Example 4: Create a weakly typed distinct type named BONUS that is based on an INTEGER data type.

```
CREATE TYPE BONUS AS INTEGER WITH WEAK TYPE RULES
```

Because it is defined with weak type rules, cast functions are not generated for the weakly typed distinct type called BONUS.

CREATE VARIABLE

The CREATE VARIABLE statement defines a global variable at the application server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSVARIABLES catalog table:
 - The INSERT privilege on the table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

If a distinct type or sequence is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the distinct type or sequence identified in the statement:
 - The USAGE privilege on the distinct type or sequence, and
 - The USAGE privilege on the schema containing the distinct type or sequence
- Database administrator authority

If a function is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
 - The EXECUTE privilege on the function, and
 - The USAGE privilege on the schema containing the function
- Database administrator authority

If a global variable is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement:
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

If a table or view is referenced directly or indirectly, the privileges held by the authorization ID of the statement must include at least one of the following:

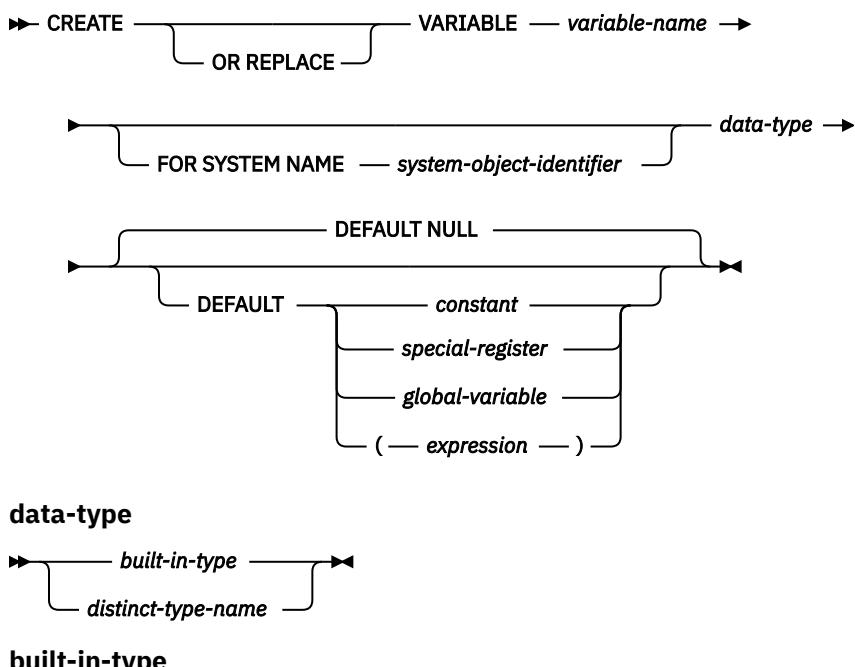

- For each table and view referenced directly or indirectly:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
 - Database administrator authority

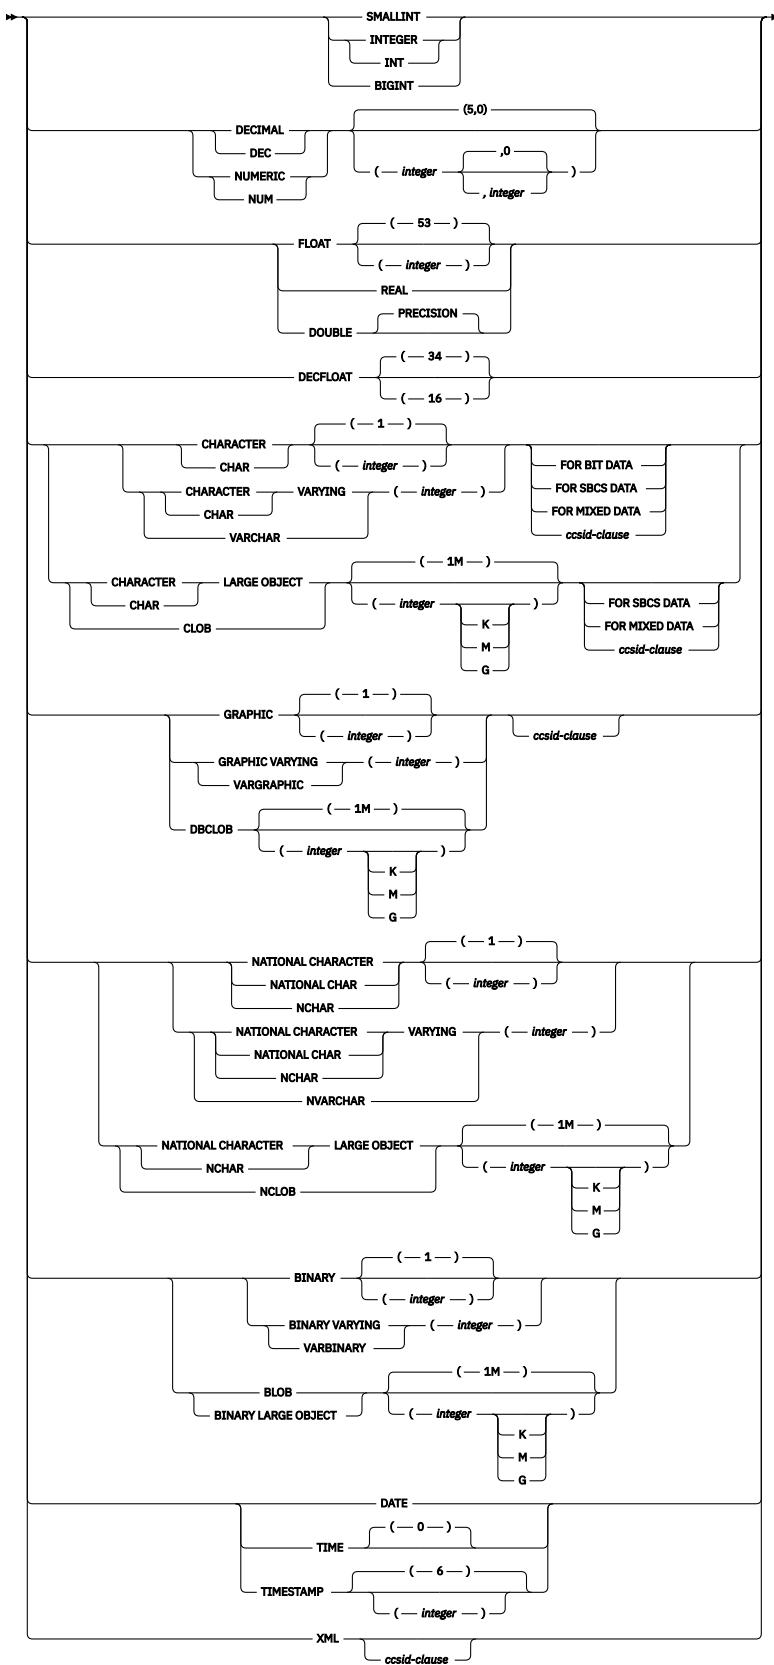

To replace an existing variable, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the service program for the variable
 - All authorities needed to DROP the variable
 - The system authority *READ to the SYSVARIABLES catalog table
 - Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Sequence](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

ccsid-clause

►► CCSID — *integer* ►►

Description

OR REPLACE

Specifies to replace the definition for the variable if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the variable are not affected. This option is ignored if a definition for the variable does not exist at the current server.

variable-name

Names the global variable. The name, including the implicit or explicit qualifier, must not identify a global variable that already exists at the current server. If a qualified variable name is specified, the *schema-name* cannot be QSYS2, QSYS, QTEMP, or SYSIBM.

If SQL names were specified, the variable will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the variable will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the variable will be created in the current library (*CURLIB).
- Otherwise, the variable will be created in the current schema.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the global variable. *system-object-identifier* must not be the same as a global variable that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *variable-name* must not be a valid system object name.

data-type

Specifies the data type or the global variable.

built-in-type

Specifies a built-in data type. See “[CREATE TABLE](#)” on page 945 for a more complete description of each built-in data type.

distinct-type-name

Specifies a distinct type. The length, precision, and scale of the global variable are, respectively, and length, precision, and scale of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path. The same limitations that apply to built-in types apply to the source type of the distinct type.

DEFAULT

Specifies a default value for the global variable. The value can be a constant, a special register, a global variable, an expression, or the keyword NULL. The default value is determined on its first reference if a value is not explicitly specified. If a default value is not specified, the variable is initialized to the null value.

The default expression must not modify SQL data or perform an external action. The expression must be assignment compatible with the data type of the variable.

All tables, views, aliases, distinct types, sequences, global variables, and user-defined functions referenced in the default expression must exist at the current server when the global variable is created. The table or view that an alias refers to must also exist when the variable is created.

This includes objects in library QTEMP. While objects in QTEMP can be referenced in the default expression, dropping those objects in QTEMP will not cause the global variable to be dropped.

Notes

Session scope: Global variables have a session scope. This means that although they are available to all sessions that are active on the database, their value is private for each session.

Modifications to the value of a global variable: Modifications to the value of a global variable are not under transaction control. The value of the global variable is preserved when a transaction ends with either a COMMIT or a ROLLBACK statement.

Privileges to use a global variable: An attempt to read from or to write to a global variable created by this statement requires that the authorization ID attempting this action hold the appropriate privilege on the global variable. The definer of the variable is implicitly granted all privileges on the variable.

Setting of the default value: A created global variable is instantiated to its default value when it is first referenced within its given scope. Note that if a global variable is referenced in a statement, it is instantiated independently of the control flow for that statement.

Using a newly created session global variable: If a global variable is created within a session, it cannot be used by other sessions until the unit of work has been committed. However, the new global variable can be used within the session that created the variable before the unit of work commits.

Once a global variable is instantiated for a session, changes to the global variable in another session (such as DROP or GRANT) might not affect the variable that has been instantiated.

Creating the global variable: A global variable is created as a *SRVPGM object. If the variable name is a valid system name but a *SRVPGM already exists with that name, an error is issued. If the variable name is not a valid system name, a unique name is generated using the rules for generating system table names. For information about the rules for generating a name, see “[Rules for Table Name Generation](#)” on page 994.

The global variable's definition is saved in the associated service program object. If the *SRVPGM object is saved and then restored to this or another system, the catalogs are automatically updated with the definition.

During restore of the global variable:

- If a *SRVPGM object with the same system name exists, the *SRVPGM will be replaced.

If a global variable and an SQL routine have the same name, naming conflicts can be avoided by creating the global variable first.

Variable ownership: The *owner* of the variable is the user profile or group user profile of the thread executing the statement.

Variable authority: If SQL names are used, variables are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, variables are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the variable is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the variable.

Variable instantiation authorization: When a global variable is instantiated, the DEFAULT clause is evaluated using the authority of the owner of the global variable.

REPLACE rules: When a variable is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

Examples

Example 1: Create a global variable to indicate what printer to use for the session.

```
CREATE VARIABLE MYSCHHEMA.MYJOB_PRINTER VARCHAR(30)
  DEFAULT 'Default printer'
```

Example 2: Create a global variable to indicate the department where an employee works.

```
CREATE VARIABLE SCHEMA1.GV_DEPTNO INTEGER  
DEFAULT ((SELECT DEPTNO FROM HR.EMPLOYEES  
WHERE EMPUSER = SESSION_USER))
```

Example 3: Create a global variable to indicate the security level of the current user.

```
CREATE VARIABLE SCHEMA2.GV_SECURITY_LEVEL INTEGER  
DEFAULT ( GET_SECURITY_LEVEL ( SESSION_USER ))
```

CREATE VIEW

The CREATE VIEW statement creates a view on one or more tables or views at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Create Logical File (CRTL) CL command
 - *CHANGE to the data dictionary if the library into which the view is created is an SQL schema with a data dictionary
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

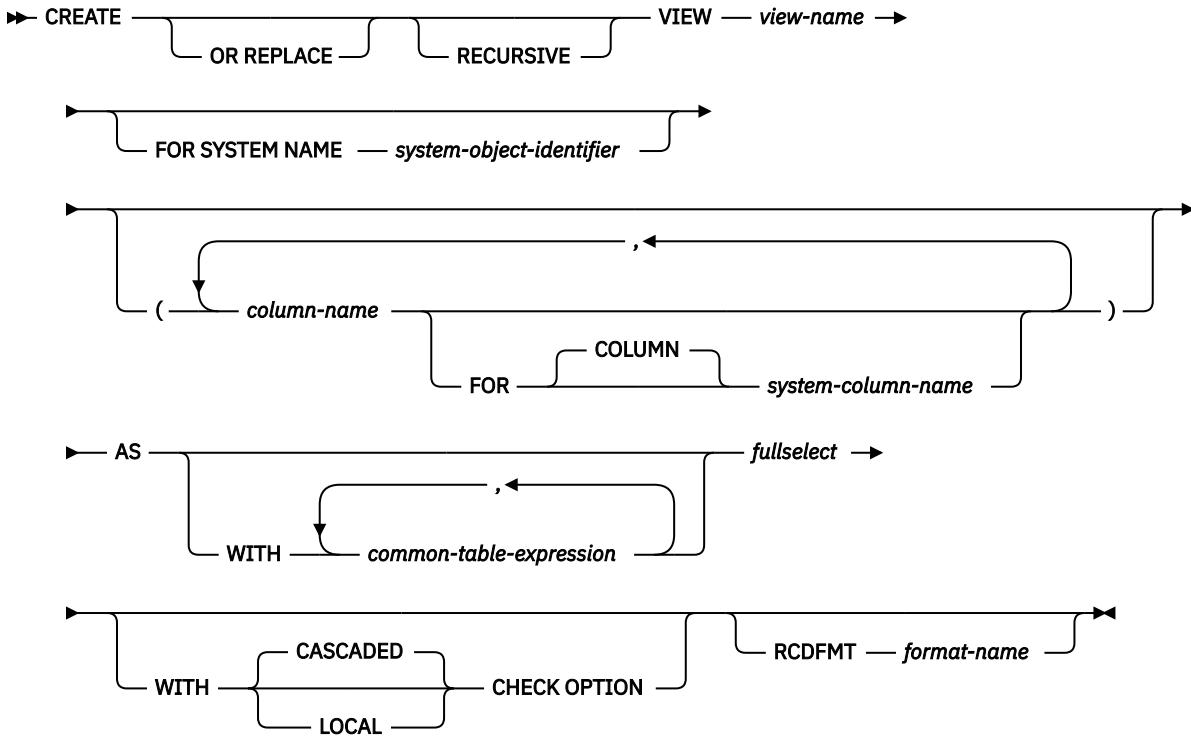

- For each table and view referenced directly through the fullselect, or indirectly through views referenced in the fullselect:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view, and
 - If the table is the only base table for the view, the system authority of *OBJMGT on the table
- Database administrator authority

To replace an existing view, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR, *OBJMGT, and *READ on the view
 - All authorities needed to DROP the view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

Description

OR REPLACE

Specifies to replace the definition for the view if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the view are not affected. The existing object cannot be a DDS-created logical file. This option is ignored if a definition for the view does not exist at the current server.

RECURSIVE

Indicates that the view is potentially recursive.

If a *fullselect* of the view contains a reference to the view itself in a FROM clause, the view is a *recursive view*. Views using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The restrictions that apply to a recursive view are similar to those for a recursive common table expression:

- A list of *column-names* must be specified following the *view-name* unless the result columns of the *fullselect* are already named.
- The UNION ALL set operator must be specified.
- The first *fullselect* of the first union (the initialization *fullselect*) must not include a reference to the view itself in any FROM clause.
- Each *fullselect* that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, or HAVING clauses.
- The FROM clauses of each *fullselect* can include at most one reference to the view that is part of a recursion cycle.
- The table being defined in the *common-table-expression* cannot be referenced in a subquery of a *fullselect* that defines the *common-table-expression*.

- LEFT OUTER JOIN and FULL OUTER JOIN are not allowed if the *common-table-expression* is the right operand. RIGHT OUTER JOIN and FULL OUTER JOIN are not allowed if the *common-table-expression* is the left operand.

If a column name of the view is referred to in the iterative fullselect, the attributes of the result columns are determined using the rules for result columns. For more information see “[Rules for result data types](#)” on page 99.

Recursive views are not allowed if the query specifies:

- a distributed table,
- a table with a read trigger,
- a table referenced directly or indirectly in the fullselect must not be a DDS-created logical file, or
- a logical file built over multiple physical file members.

view-name

Names the view. The name, including the implicit or explicit qualifier, must not be the same as an alias, file, index, table, or view that already exists at the current server.

If SQL names were specified, the view will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the view will be created in the schema that is specified by the qualifier. If not qualified and there is no default schema, the view name will be created in the same schema as the first table specified on the first FROM clause (including FROM clauses in any common table expressions or nested table expression). If no tables are referenced in the fullselect, the view will be created in the same schema as the first user defined table function. If no table or user defined table function is referenced in the fullselect, the current library (*CURLIB) will be used.

If a view name is not a valid system name and the FOR SYSTEM NAME clause is not used, Db2 for i will generate a system name. For information about the rules for generating the name, see “[Rules for Table Name Generation](#)” on page 994.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the view. *system-object-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *view-name* must not be a valid system object name.

(*column-name*, ...)

Names the columns in the view. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* and *system-column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the view inherit the names of the columns and system names of the columns of the result table of the fullselect.

A list of column names (and system column names) must be specified if the result table of the subselect has duplicate column names, duplicate system column names, or an unnamed column. For more information about unnamed columns, see “[Names of result columns](#)” on page 601.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the view or for a column-name of the view.

If the *system-column-name* is not specified, and the *column-name* is not a valid *system-column-name*, a system column name is generated. For more information about how system column names are generated, see “[Rules for Column Name Generation](#)” on page 993.

AS

Defines the view.

WITH common-table-expression

Defines a common table expression for use with the fullselect that follows. For an explanation of common table expression, see “[common-table-expression](#)” on page 643.

fullselect

Defines the view. At any time, the view consists of the rows that would result if the fullselect were executed.

fullselect must not reference variables, but may reference global variables.

The maximum number of columns allowed in a view is 8000. The column name lengths and the length of the WHERE clause also reduce this number. The maximum number of base tables allowed in the view is 256.

For an explanation of *fullselect*, see “[fullselect](#)” on page 638.

common-table-expression defines a common table expression for use with the *fullselect* that follows. For more information see “[common-table-expression](#)” on page 643.

A declared temporary table must not be referenced in the *fullselect* unless the view is created in schema QTEMP.

The ORDER BY, FETCH, and OFFSET clauses may not be specified in the outer *fullselect* of the view.

WITH CASCDED CHECK OPTION or WITH LOCAL CHECK OPTION

Specifies that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

CHECK OPTION must not be specified if:

- the view is read-only
- the definition of the view includes a subquery other than a scalar fullselect in the outer select list of the view
- the definition of the view contains a non-deterministic, MODIFIES SQL DATA, or EXTERNAL ACTION function in other than the outer select list of the view
- the definition of the view contains a special register in other than the outer select list of the view
- the view references another view and that view has an INSTEAD OF trigger
- the view is recursive

If CHECK OPTION is specified for an updatable view that does not allow inserts, then the check option applies to updates only.

If CHECK OPTION is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes a CHECK OPTION. Because the definition of the view is not used, rows that do not conform to the definition of the view might be inserted or updated through the view.

The difference between the two forms of the CHECK OPTION clause, CASCDED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCDED. The view upon which another view is directly or indirectly defined is an *underlying view*.

CASCDED

The WITH CASCDED CHECK OPTION on a view V is inherited by any updatable view that is directly or indirectly dependent on V. Thus, if an updatable view is defined on V, the check option on V also applies to that view, even if WITH CHECK OPTION is not specified on that view. For example, consider the following updatable views:

```
CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CHECK OPTION
CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100
```

SQL statement	Description of result
INSERT INTO V1 VALUES(5)	Succeeds because V1 does not have a CHECK OPTION clause and it is not dependent on any other view that has a CHECK OPTION clause.
INSERT INTO V2 VALUES(5)	Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly part of the definition of V2.
INSERT INTO V3 VALUES(5)	Results in an error because V3 is dependent on V2 which has a CHECK OPTION clause and the inserted row does not conform to the definition of V2.
INSERT INTO V3 VALUES(200)	Succeeds even though it does not conform to the definition of V3 (V3 does not have the view CHECK OPTION clause specified); it does conform to the definition of V2 (which does have the view CHECK OPTION clause specified).

LOCAL

WITH LOCAL CHECK OPTION is identical to WITH CASCaded CHECK OPTION except that it is still possible to update a row so that it no longer conforms to the definition of the view when the view is defined with the WITH LOCAL CHECK OPTION. This can only happen when the view is directly or indirectly dependent on a view that was defined without either WITH CASCaded CHECK OPTION or WITH LOCAL CHECK OPTION clauses.

WITH LOCAL CHECK OPTION specifies that the search conditions of the following underlying views are checked when a row is inserted or updated:

- views that specify WITH LOCAL CHECK OPTION
- views that specify WITH CASCaded CHECK OPTION
- all underlying views of a view that specifies WITH CASCaded CHECK OPTION

In contrast, WITH CASCaded CHECK OPTION specifies that the search conditions of all underlying views are checked when a row is inserted or updated.

The difference between CASCaded and LOCAL is best shown by example. Consider the following updatable views where x and y represent either LOCAL or CASCaded:

```
V1 defined on table T0
V2 defined on V1 WITH x CHECK OPTION
V3 defined on V2
V4 defined on V3 WITH y CHECK OPTION
V5 defined on V4
```

The following table describes which views search conditions are checked during an INSERT or UPDATE operation:

Table 97. Views whose search conditions are checked during INSERT and UPDATE				
View used in INSERT or UPDATE	x = LOCAL y = LOCAL	x = CASCaded y = CASCaded	x = LOCAL y = CASCaded	x = CASCaded y = LOCAL
V1	none	none	none	none
V2	V2	V2 V1	V2	V2 V1
V3	V2	V2 V1	V2	V2 V1
V4	V4 V2	V4 V3 V2 V1	V4 V3 V2 V1	V4 V2 V1
V5	V4 V2	V4 V3 V2 V1	V4 V3 V2 V1	V4 V2 V1

RCDFMT *format-name*

An unqualified name that designates the IBM i record format name of the view. A *format-name* is a system identifier.

If a record format name is not specified, the *format-name* is the same as the *system-object-name* of the view.

Notes

View ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the view is created exists, the *owner* of the view is that user profile.
- Otherwise, the *owner* of the view is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the view is the user profile or group user profile of the thread executing the statement.

View authority: If SQL names are used, views are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, views are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the view is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the view.

The owner always acquires the SELECT privilege WITH GRANT OPTION on the view and the authorization to drop the view.

The owner can also acquire the INSERT, UPDATE, and DELETE privileges on the view. If the view is not read-only, then the same privileges will be acquired on the new view as the owner has on the table or view identified in the first FROM clause of the fullselect. These privileges can be granted only if the privileges from which they are derived can also be granted.

REPLACE rules: When a view is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved. However, unlike other objects, REPLACE of a view will generate a ZC (change object) journal audit entry.
- Any INSTEAD OF triggers defined for the view are dropped (any triggers that reference the view are not dropped).
- Any views and materialized query tables dependent on the view will be recreated, if possible. If it is not possible to recreate a dependent view or materialized query table, an error is returned.

Deletable views: A view is *deletable* if an INSTEAD OF trigger for the delete operation has been defined for the view, or if all of the following are true:

- The outer fullselect identifies only one base table or deletable view that is not a catalog table or view. It cannot be a nested table expression, table function, or a table with a FOR SYSTEM_TIME clause.
- The outer fullselect does not include a VALUES clause.
- The outer fullselect does not include a GROUP BY clause or HAVING clause.
- The outer fullselect does not include aggregate functions in the select list.
- The outer fullselect does not include a UNION, UNION ALL, EXCEPT, or INTERSECT operator.
- The outer fullselect does not include the DISTINCT clause.

Updatable views: A view is *updatable* if an INSTEAD OF trigger for the update operation has been defined for the view, or if all of the following are true:

- independent of an INSTEAD OF trigger for delete, the view is deletable

- at least one column of the view is updatable.

A column of a view is *updatable* if an INSTEAD OF trigger for the update operation has been defined for the view, or if the corresponding result column of the *subselect* is derived solely from a column of a table or an updatable column of another view (that is, it is not derived from an expression that contains an operator, scalar function, constant, or a column that itself is derived from such expressions).

Insertable views: A view is *insertable* if an INSTEAD OF trigger has been defined for the view, or if at least one column of the view is updatable.

Read-only views: A view is *read-only* if it is not deletable.

A read-only view cannot be the object of an INSERT, UPDATE, or DELETE statement.

Special registers for temporal support: The value of the CURRENT TEMPORAL SYSTEM_TIME special register has no impact on the query expression that defines a view while it is being defined. When a view is used in an SQL statement, the value of the CURRENT TEMPORAL SYSTEM_TIME special register for the session processing the SQL statement is applied to the view if the value of the SYSTIME option is YES.

Unqualified table names: If the CREATE VIEW statement refers to an unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression *table-identifiers* that are specified in the *fullselect*, the name identifies the common table expression that is in the innermost scope.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

Considerations for implicitly hidden columns: It is possible that the result table of the fullselect will include a column of the base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

Collating sequence: The view is created with the collating sequence in effect at the time the CREATE VIEW statement is executed. The collating sequence of the view applies to all comparisons involving SBCS data and mixed data in the view fullselect. When the view is included in a query, an intermediate result table is generated from the view fullselect. The collating sequence in effect when the query is executed applies to any selection specified in the query.

View attributes: Views are created as nonkeyed logical files. When a view is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Logical File (CRTL) command.

The date and time format used for date and time result columns is ISO.

A view created over a distributed table is created on all of the systems across which the table is distributed. If a view is created over more than one distributed table, and those tables are not distributed using the same nodegroup, then the view is created only on the system that performs the CREATE VIEW statement. For more information about distributed tables, see the DB2 Multisystem topic collection.

Identity and row change timestamp columns: A column of a view is considered an identity or row change timestamp column if the element of the corresponding column in the fullselect of the view definition is the name of an identity or row change timestamp column of a table, or the name of a column of a view which directly or indirectly maps to the name of an identity or row change timestamp column of a base table. In all other cases, the columns of a view will not get the identity or row change timestamp property. For example:

- the select-list of the view definition includes multiple instances of the name of an identity column (that is, selecting the same column more than once)
- the view definition involves a join
- a column in the view definition includes an expression that refers to an identity column
- the view definition includes a UNION or INTERSECT

Examples

Example 1: Create a view named MA_PROJ over the PROJECT table that contains only those rows with a project number (PROJNO) starting with the letters 'MA'.

```
CREATE VIEW MA_PROJ  
AS SELECT * FROM PROJECT  
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

Example 2: Create a view as in example 1, but select only the columns for project number (PROJNO), project name (PROJNAME) and employee in charge of the project (RESPEMP).

```
CREATE VIEW MA_PROJ  
AS SELECT PROJNO, PROJNAME, RESPEMP FROM PROJECT  
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

Example 3: Create a view as in example 2, but, in the view, call the column for the employee in charge of the project IN_CHARGE.

```
CREATE VIEW MA_PROJ (PROJNO, PROJNAME, IN_CHARGE)  
AS SELECT PROJNO, PROJNAME, RESPEMP FROM PROJECT  
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

Note: Even though you are changing only one of the column names, the names of all three columns in the view must be listed in the parentheses that follow MA_PROJ.

Example 4: Create a view named PRJ_LEADER that contains the first four columns (PROJNO, PROJNAME, DEPTNO, RESPEMP) from the PROJECT table together with the last name (LASTNAME) of the person who is responsible for the project (RESPEMP). Obtain the name from the EMPLOYEE table by matching EMPNO in EMPLOYEE to RESEMP in PROJECT.

```
CREATE VIEW PRJ_LEADER  
AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME  
FROM PROJECT, EMPLOYEE  
WHERE RESPEMP = EMPNO
```

Example 5: Create a view as in example 4, but in addition to the columns PROJNO, PROJNAME, DEPTNO, RESEMP and LASTNAME, show the total pay (SALARY + BONUS +COMM) of the employee who is responsible. Also select only those projects with mean staffing (PRSTAFF) greater than one.

```
CREATE VIEW PRJ_LEADER (PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME, TOTAL_PAY)  
AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME, SALARY+BONUS+COMM  
FROM PROJECT, EMPLOYEE  
WHERE RESPEMP = EMPNO AND PRSTAFF > 1
```

Example 6: Create a recursive view that returns a similar result as a common table expression, see "["Example 1: Single level explosion" on page 647.](#)

```
CREATE RECURSIVE VIEW RPL (PART, SUBPART, QUANTITY) AS  
SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY  
FROM PARTLIST ROOT  
WHERE ROOT.PART = '01'  
UNION ALL  
SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY  
FROM RPL PARENT, PARTLIST CHILD  
WHERE PARENT.SUBPART = CHILD.PART  
  
SELECT DISTINCT *  
FROM RPL  
ORDER BY PART, SUBPART, QUANTITY
```

DEALLOCATE DESCRIPTOR

The DEALLOCATE DESCRIPTOR statement deallocates an SQL descriptor.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The descriptor known in this local scope is deallocated.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The descriptor known to any program that executes using the same database connection is deallocated.

SQL-descriptor-name

Names the descriptor to deallocate. The name must identify a descriptor that already exists with the specified scope.

Notes

Descriptor persistence: Local and global descriptors are also implicitly deallocated. For more information, see [Descriptor persistence](#)

Examples

Deallocate a descriptor called 'NEWDA'.

```
EXEC SQL DEALLOCATE DESCRIPTOR 'NEWDA'
```

DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

Authorization

No authorization is required to use this statement. However to use OPEN or FETCH for the cursor, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the SELECT statement of the cursor:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

The SELECT statement of the cursor is one of the following:

- The prepared *select-statement* identified by the *statement-name*.
- The specified *select-statement*.

If **statement-name** is specified:

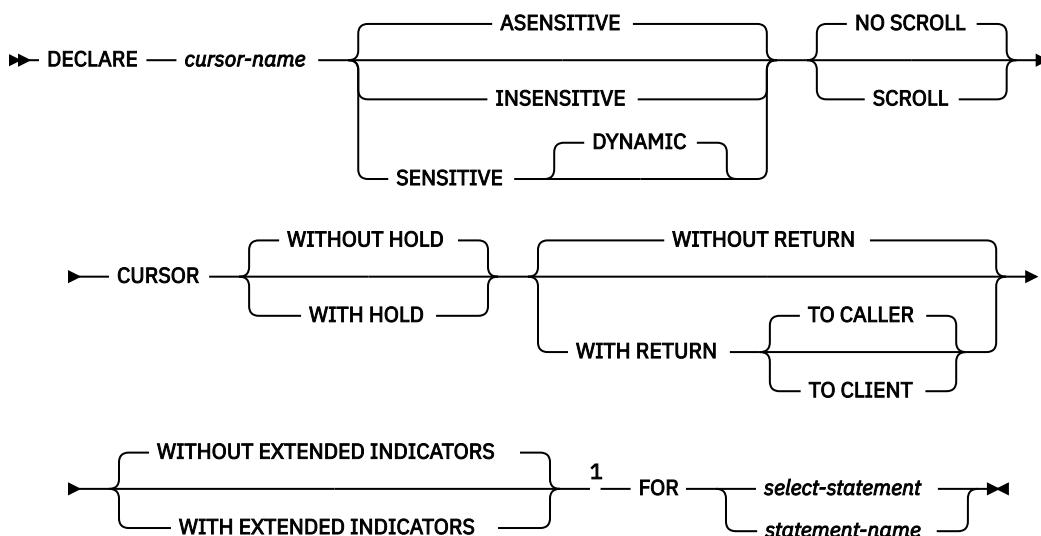

- The authorization ID of the statement is the run-time authorization ID unless USRPRF(*OWNER) and DYNUSRPRF(*OWNER) were specified on the CRTSQLxxx command when the program was created. For more information, see [“Authorization IDs and authorization names” on page 58](#).
- The authorization check is performed when the *select-statement* is prepared unless DLYPRP(*YES) is specified on the CRTSQLxxx command.
- The authorization check is performed when the cursor is opened for programs compiled with the DLYPRP(*YES) parameter.

If the **select-statement** is specified:

- If USRPRF(*OWNER) or USRPRF(*NAMING) with SQL naming was specified on the CRTSQLxxx command, the authorization ID of the statement is the owner of the SQL program or package.
- If USRPRF(*USER) or USRPRF(*NAMING) with system naming was specified on the CRTSQLxxx command, the authorization ID of the statement is the run-time authorization ID.
- In REXX, the authorization ID of the statement is the run-time authorization ID.
- The authorization check is performed when the cursor is opened.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

Notes:

¹ The HOLD, RETURN, and EXTENDED INDICATORS clauses can be specified in any order.

Description

cursor-name

Names a cursor. The name must not be the same as the name of another cursor declared in your source program.

ASENSITIVE, SENSITIVE, or INSENSITIVE

Specifies whether the cursor is asensitive, sensitive, or insensitive to changes. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, ASESENTIVE is the default.

ASENSITIVE

Specifies that the cursor may behave as SENSITIVE or INSENSITIVE depending on how the *select-statement* is optimized.

SENSITIVE

Specifies that changes made to the database after the cursor is opened are visible in the result table. The cursor has some level of sensitivity to any updates or deletes made to the rows underlying its result table after the cursor is opened. The cursor is always sensitive to positioned updates or deletes using the same cursor. Additionally, the cursor can have sensitivity to changes made outside this cursor. If the database manager cannot make changes visible to the cursor, then an error is returned. The database manager cannot make changes visible to the cursor when the cursor implicitly becomes read-only. (See [Result table of a cursor](#).) If SENSITIVE is specified, the SELECT statement cannot contain a *data-change-table-reference*.

INSENSITIVE

Specifies that once the cursor is opened, it does not have sensitivity to inserts, updates, or deletes performed by this or any other activation group. If INSENSITIVE is specified, the cursor is read-only and a temporary result is created when the cursor is opened. In addition, the SELECT statement cannot contain a UPDATE clause and the application must allow a copy of the data (ALWCPYDTA(*OPTIMIZE) or ALWCPYDTA(*YES)).

NO SCROLL or SCROLL

Specifies whether the cursor is scrollable or not scrollable. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, NO SCROLL is the default.

NO SCROLL

Specifies that the cursor is not scrollable.

SCROLL

Specifies that the cursor is scrollable. The cursor may or may not have immediate sensitivity to inserts, updates, and deletes done by other activation groups.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, WITHOUT HOLD is the default.

WITHOUT HOLD

Does not prevent the cursor from being closed as a consequence of a commit operation.

WITH HOLD

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared using the WITH HOLD clause is implicitly closed at commit time only if the connection associated with the cursor is ended during the commit operation.

When WITH HOLD is specified, a commit operation commits all the changes in the current unit of work, and releases all locks except those that are required to maintain the cursor position. Afterward, a FETCH statement is required before a Positioned UPDATE or DELETE statement can be executed.

All cursors are implicitly closed by a CONNECT (Type 1) or rollback operation. All cursors associated with a connection are implicitly closed by a disconnect of the connection. A cursor is also implicitly closed by a commit operation if WITH HOLD is not specified, or if the connection associated with the cursor is in the release-pending state.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the WITH HOLD option.

WITHOUT RETURN or WITH RETURN

Specifies that the result table of the cursor is intended to be used as a procedure result set. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, WITHOUT RETURN is the default.

WITHOUT RETURN

Specifies that the result table of the cursor is not intended to be used as a procedure result set.

WITH RETURN

Specifies that the result table of the cursor is intended to be used as a procedure result set. If the DECLARE CURSOR statement is not contained within the source code for a procedure, the clause is ignored.

For SQL procedures, result sets are only returned if a DYNAMIC RESULT SETS clause with a nonzero maximum number of result sets is specified on the procedure definition.

- Cursors defined by using the WITH RETURN clause that are still open when the procedure ends define the result sets for the procedure. All other open cursors are closed when the procedure ends, provided the procedure was not created with CLOSQLCSR(*ENDACTGRP).
- If no cursors in the stored procedure are defined by using the WITH RETURN or WITHOUT RETURN clause, then any cursor that is open when the stored procedure ends potentially becomes a result set cursor.
- See the DYNAMIC RESULT SETS clause in [“CREATE PROCEDURE \(SQL\)” on page 920](#) for further considerations that determine a procedure's result sets.

For external procedures:

- Any cursors that are defined by using the WITH RETURN clause (or identified as a result set cursor in a SET RESULT SETS statement) and that are still open when the procedure ends define the potential result sets for the procedure, provided the procedure was not created with CLOSQLCSR(*ENDACTGRP). All other open cursors remain open.
- If no cursors in the stored procedure are defined by using the WITH RETURN or WITHOUT RETURN clause, and no cursors are identified as a result set cursor in a SET RESULT SETS statement, then any cursor that is open when the stored procedure ends potentially becomes a result set cursor.
- See the DYNAMIC RESULT SETS clause in [“CREATE PROCEDURE \(external\)” on page 906](#) for further considerations that determine a procedure's result sets.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

TO CALLER

Specifies that the cursor can return a result set to the caller of the procedure. For example, if the caller is a client application, the result set is returned to the client application.

TO CLIENT

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger called the procedure either directly or indirectly, result sets cannot be returned to the client and the cursor will be closed after the procedure finishes.

TO CLIENT may be necessary if the result set is returned from an ILE program with multiple modules.

WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS

Specifies whether extended indicators are enabled. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is the attribute specified on the containing program or service program.

WITHOUT EXTENDED INDICATORS

Specifies that extended indicator variables are not enabled, and only updatable columns are allowed in the implicit or explicit UPDATE clause or the *select-statement*.

WITH EXTENDED INDICATORS

Specifies that extended indicator variables are enabled, and non-updatable columns are allowed in the implicit or explicit UPDATE clause of the *select-statement*.

select-statement

Specifies the SELECT statement of the cursor. See “[select-statement](#)” on page 642 for more information.

The *select-statement* must not include parameter markers (except for REXX), but can include references to variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of variables and the statement must be prepared.

statement-name

The SELECT statement of the cursor is the prepared *select-statement* identified by the *statement-name* when the cursor is opened. The *statement-name* must not be identical to a *statement-name* specified in another DECLARE CURSOR statement of the source program. See “[“PREPARE”](#) on page 1236 for an explanation of prepared statements.

Notes

Placement of DECLARE CURSOR: The DECLARE CURSOR statement must precede all statements that explicitly reference the cursor by name, except in C and PL/I.

Result table of a cursor: A cursor in the open state designates a *result table* and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

A cursor is *deletable* if all of the following are true:

- The outer fullselect identifies only one base table or deletable view that is not a catalog table or view and is not in a nested table expression.
- The outer fullselect does not include a VALUES clause.
- The outer fullselect does not include a GROUP BY clause or HAVING clause.
- The outer fullselect does not include aggregate functions in the select list.
- The outer fullselect does not include a UNION, UNION ALL, EXCEPT, or INTERSECT operator.
- The *select-clause* of the outer fullselect does not include the DISTINCT clause.
- The outer fullselect does not contain a FOR SYSTEM_TIME period specification.
- The outer fullselect does not include a *data-change-table-reference* in the FROM clause
- The *select-statement* does not contain an ORDER BY clause and does not contain the UPDATE clause and SENSITIVE is not specified in the DECLARE CURSOR statement
- The *select-statement* does not include a FOR READ ONLY clause.
- The result of the outer fullselect does not make use of a temporary table.
- The *select-statement* does not include the SCROLL keyword, or the SENSITIVE keyword or UPDATE clause is also specified.
- The select list does not include a DATALINK column unless a UPDATE clause is specified.

A result column in the select list of the outer fullselect associated with a cursor is *updatable* if all of the following are true:

- The cursor is deletable.
- The result column is derived solely from a column of a table or an updatable column of a view. That is, at least one result column must not be derived from an expression that contains an operator, scalar function, constant, or a column that itself is derived from such expressions.

A cursor is *read-only* if it is not deletable.

If the UPDATE clause is omitted, only the columns in the SELECT clause of the subselect that can be updated can be changed.

If UPDATE is specified without a list of column names, then the list of columns that can appear as targets in the assignment clause of subsequent positioned UPDATE statements identifying this cursor is determined as follows:

- If WITH EXTENDED INDICATORS is specified, all the columns of the table or view identified in the first FROM clause of the fullselect.
- Otherwise, only the updatable columns of the table or view identified in the first FROM clause of the fullselect.

If UPDATE is specified with a list of column names, only the columns specified in the list of column names can appear as targets in the assignment clause in subsequent positioned UPDATE statements identifying this cursor.

Scope of a cursor: The scope of *cursor-name* is the source program in which it is defined; that is, the program submitted to the precompiler. Thus, a cursor can only be referenced by statements that are precompiled with the cursor declaration. For example, a program called from another separately compiled program cannot use a cursor that was opened by the calling program.

The scope of cursor-name is also limited to the thread in which the program that contains the cursor is running. For example, if the same program is running in two separate threads in the same job, the second thread cannot use a cursor that was opened by the first thread.

A cursor can only be referred to in the same instance of the program in the program stack unless CLOSQLCSR(*ENDJOB), CLOSQLCSR(*ENDSQL), or CLOSQLCSR(*ENDACTGRP) is specified on the CRTSQLxxx commands.

- If CLOSQLCSR(*ENDJOB) is specified, the cursor can be referred to by any instance of the program on the program stack.
- If CLOSQLCSR(*ENDSQL) is specified, the cursor can be referred to by any instance of the program on the program stack until the last SQL program on the program stack ends.
- If CLOSQLCSR(*ENDACTGRP) is specified, the cursor can be referred to by all instances of the module in the activation group until the activation group ends.

Although the scope of a cursor is the program in which it is declared, each package created from the program includes a separate instance of the cursor and more than one cursor can exist at run time. For example, assume a program using CONNECT (Type 2) statements connects to location X and location Y in the following sequence:

```
EXEC SQL DECLARE C CURSOR FOR...
EXEC SQL CONNECT TO X;
EXEC SQL OPEN C;
EXEC SQL FETCH C INTO...
EXEC SQL CONNECT TO Y;
EXEC SQL OPEN C;
EXEC SQL FETCH C INTO...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results may be different. If the SELECT statement of a cursor contains CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP, all references to these special registers will yield the same respective datetime value on each FETCH. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

Using sequence expressions: For information regarding using NEXT VALUE and PREVIOUS VALUE expressions with a cursor, see [Using sequence expressions with a cursor](#).

Blocking of data: For more efficient processing of data, the database manager can block data for read-only cursors. If a cursor is not going to be used in a Positioned UPDATE or DELETE statement, it should be declared as FOR READ ONLY.

Usage in REXX: If variables are used on the DECLARE CURSOR statement within a REXX procedure, then the DECLARE CURSOR must be the object of a PREPARE and EXECUTE.

Temporary results: Certain *select-statements* may be implemented as temporary result tables.

- A temporary result table is created when:
 - INSENSITIVE is specified
 - The ORDER BY and GROUP BY clauses specify different columns or columns in a different order.
 - The ORDER BY and GROUP BY clauses include a user-defined function or one of the following scalar functions: DLVALUE, DLURLPATH, DLURLPATHONLY, DLURLSERVER, DLURLSCHEME, or DLURLCOMPLETE for DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.
 - The UNION, EXCEPT, INTERSECT, or DISTINCT clauses are specified.
 - The ORDER BY or GROUP BY clauses specify columns which are not all from the same table.
 - A logical file defined by the JOINDFT data definition specifications (DDS) keyword is joined to another file.
 - A logical file that is based on multiple database file members is specified.
 - The CURRENT or RELATIVE scroll options are specified on the FETCH statement when the select statement of the DECLARE CURSOR contains a GROUP BY clause.
 - The FETCH FIRST n ROWS ONLY clause is specified.
- Queries that include a subquery where:
 - The outermost query does not provide correlated values to any inner subselects.
 - No IN, = ANY, = SOME, or <> ALL subqueries are referenced by the outermost query.

Cursor sensitivity: Scrollable, sensitive cursors with an OFFSET and/or FETCH FIRST clause may return rows either before the specified offset or after the specified number of rows if:

- update, delete, or insert operations occur against the underlying tables of the cursor while fetching data through the cursor, and
- the fetch operations against the cursor attempt to return the same rows that were previously fetched by the cursor.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- DYNAMIC SCROLL is a synonym for SENSITIVE DYNAMIC SCROLL

Examples

Example 1: Declare C1 as the cursor of a query to retrieve data from the table DEPARTMENT. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DEPARTMENT
      WHERE ADMRDEPT = 'A00';
```

Example 2: Declare C1 as the cursor of a query to retrieve data from the table DEPARTMENT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DEPARTMENT
```

```
WHERE ADMRDEPT = 'A00'  
FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

Example 3: Declare C2 as the cursor for a statement named STMT2.

```
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

Example 4: Declare C3 as the cursor for a query to be used in positioned updates of the table EMPLOYEE. Allow the completed updates to be committed from time to time without closing the cursor.

```
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR  
SELECT *  
FROM EMPLOYEE  
FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of explicitly specifying the columns to be updated, an UPDATE clause could have been used without naming the columns. This would allow all the updatable columns of the table to be updated. Since this cursor is updatable, it can also be used to delete rows from the table.

Example 5: In a C program, use the cursor C1 to fetch the values for a given project (PROJNO) from the first four columns of the EMPPROJECT table a row at a time and put them into the following host variables: EMP(CHAR(6)), PRJ(CHAR(6)), ACT(SMALLINT) and TIM(DECIMAL(5,2)). Obtain the value of the project to search for from the host variable SEARCH_PRJ (CHAR(6)). Dynamically prepare the *select-statement* to allow the project to search by to be specified when the program is executed.

```
void main ()  
{  
    EXEC SQL BEGIN DECLARE SECTION;  
    char        EMP[7];  
    char        PRJ[7];  
    char        SEARCH_PRJ[7];  
    short       ACT;  
    double      TIM;  
    char        SELECT_STMT[201];  
    EXEC SQL END DECLARE SECTION;  
    EXEC SQL INCLUDE SQLCA;  
  
    strcpy(SELECT_STMT, "SELECT EMPNO, PROJNO, ACTNO, EMPTIME \  
           FROM EMPPROJECT \  
           WHERE PROJNO = ?");  
    .  
    .  
    EXEC SQL PREPARE SELECT_PRJ FROM :SELECT_STMT;  
    EXEC SQL DECLARE C1 CURSOR FOR SELECT_PRJ;  
/* Obtain the value for SEARCH_PRJ from the user. */  
    .  
    .  
    EXEC SQL OPEN C1 USING :SEARCH_PRJ;  
    EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM;  
    if (strcmp(SQLSTATE, "02000", 5) )  
    {  
        data_not_found();  
    }  
    else  
    {  
        while (strcmp(SQLSTATE, "00", 2) || strcmp(SQLSTATE, "01", 2) )  
        {  
            EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM;  
        }  
    }  
    EXEC SQL CLOSE C1;  
    .  
    .  
}
```

Example 6: The DECLARE CURSOR statement associates the cursor name C1 with the results of the SELECT. C1 is an updatable, scrollable cursor.

```
EXEC SQL DECLARE C1 SENSITIVE SCROLL CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM TDEPT
  WHERE ADMRDEPT = 'A00';
```

Example 7: Declare a cursor in order to fetch values from four columns and assign the values to variables using the Serializable (RR) isolation level:

```
DECLARE CURSOR1 CURSOR FOR
  SELECT COL1, COL2, COL3, COL4
  FROM TBLNAME WHERE COL1 = :varname
  WITH RR
```

Example 8: Assume that the EMPLOYEE table has been altered to add a generated column, WEEKLYPAY, that calculates the weekly pay based on the yearly salary. Declare a cursor to retrieve the system generated column value from a row to be inserted.

```
DECLARE C2 CURSOR FOR
  SELECT E.WEEKLYPAY
  FROM FINAL TABLE
  (INSERT INTO EMPLOYEE
    (EMPNO, FIRSTNME, MIDINIT, LASTNAME, EDLEVEL, SALARY)
    VALUES('000420', 'Peter', 'U', 'Bender', 16, 31842)) AS E;
```

DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description of the temporary table. When the application process ends, the temporary table is dropped.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If the LIKE or AS *select-statement* clause is specified, the privileges held by the authorization ID of the statement must include at least one of the following on any table or view specified in the LIKE clause or as-*result-table* clause:

- The SELECT privilege for the table or view
 - The LIKE clause and AS *select-statement* using the WITH NO DATA clause do not require *READ authority.
- Ownership of the table or view
- Database administrator authority

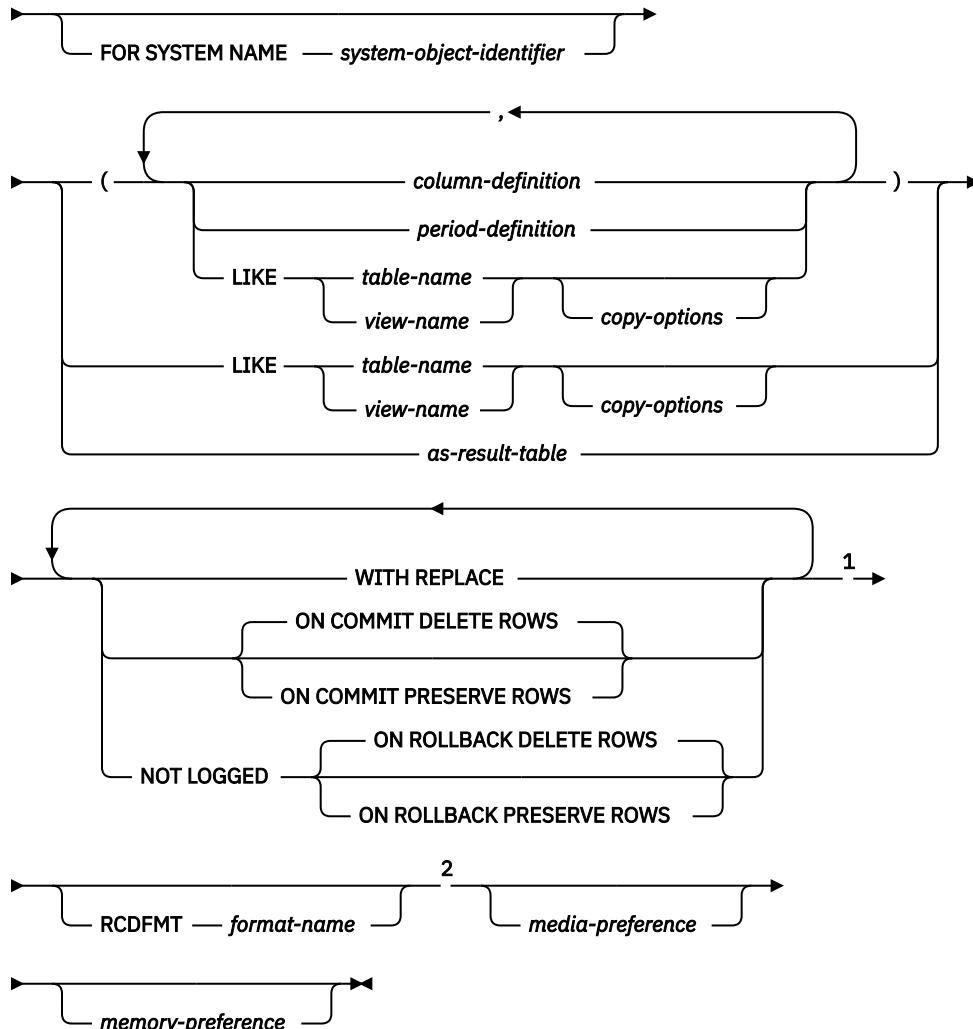

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The USAGE privilege on the schema containing the distinct type
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

► DECLARE GLOBAL TEMPORARY TABLE — *table-name* →

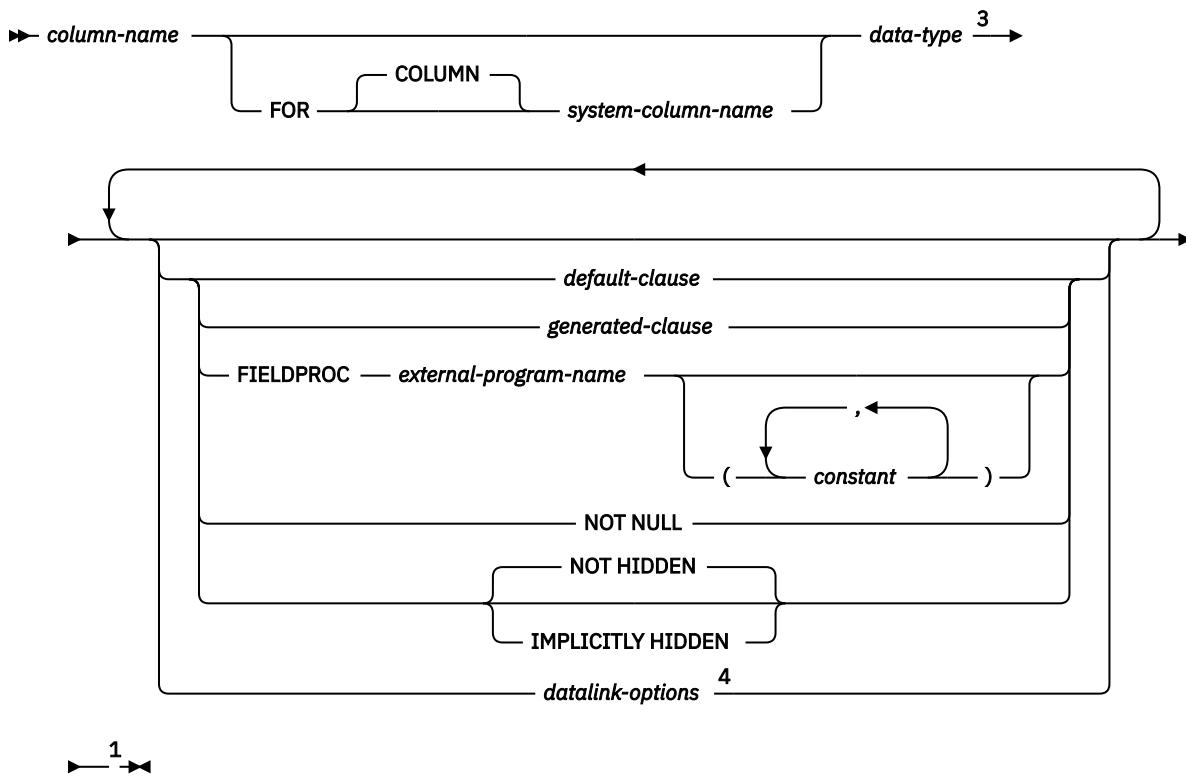

media-preference

► UNIT ANY
UNIT SSD

memory-preference

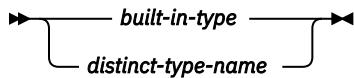

► KEEP IN MEMORY — NO
YES

column-definition

1

data-type

Notes:

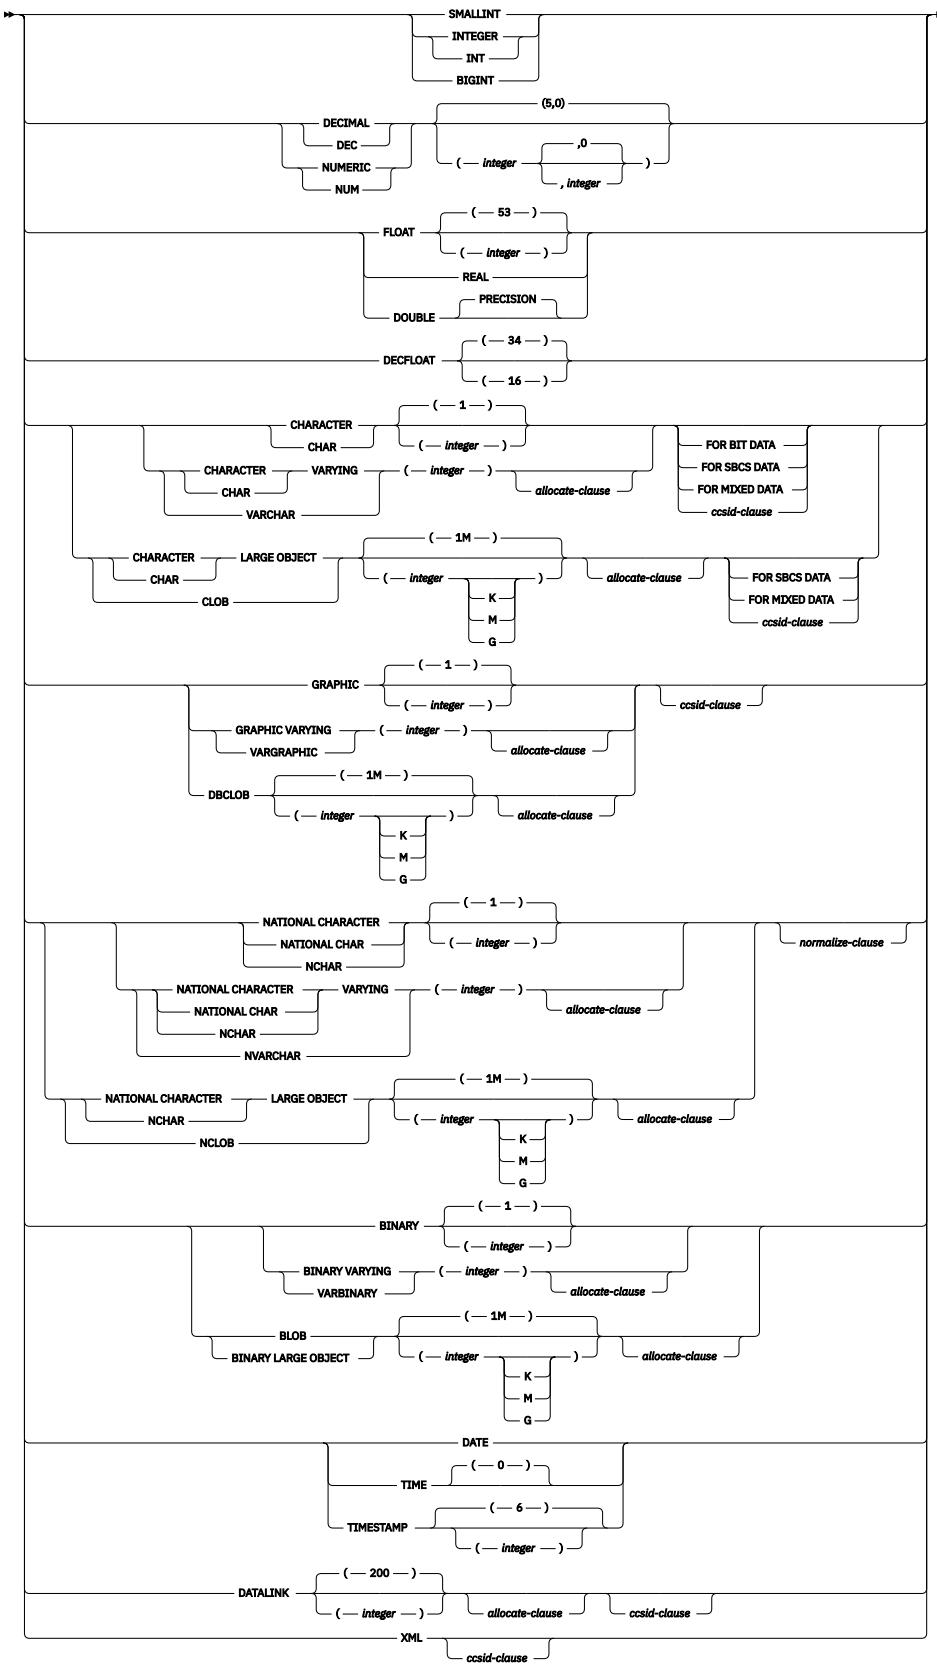

¹ The same clause must not be specified more than once.

² The optional clauses can be specified in any order.

³ data-type is optional for row change timestamp columns, row-begin and row-end columns, and transaction-start-ID columns.

⁴ The datalink-options can only be specified for DATALINKs and distinct-types sourced on DATALINKs.

built-in-type

ccsid-clause

►► CCSID — *integer* —►►
 —►► *normalize-clause* —►►

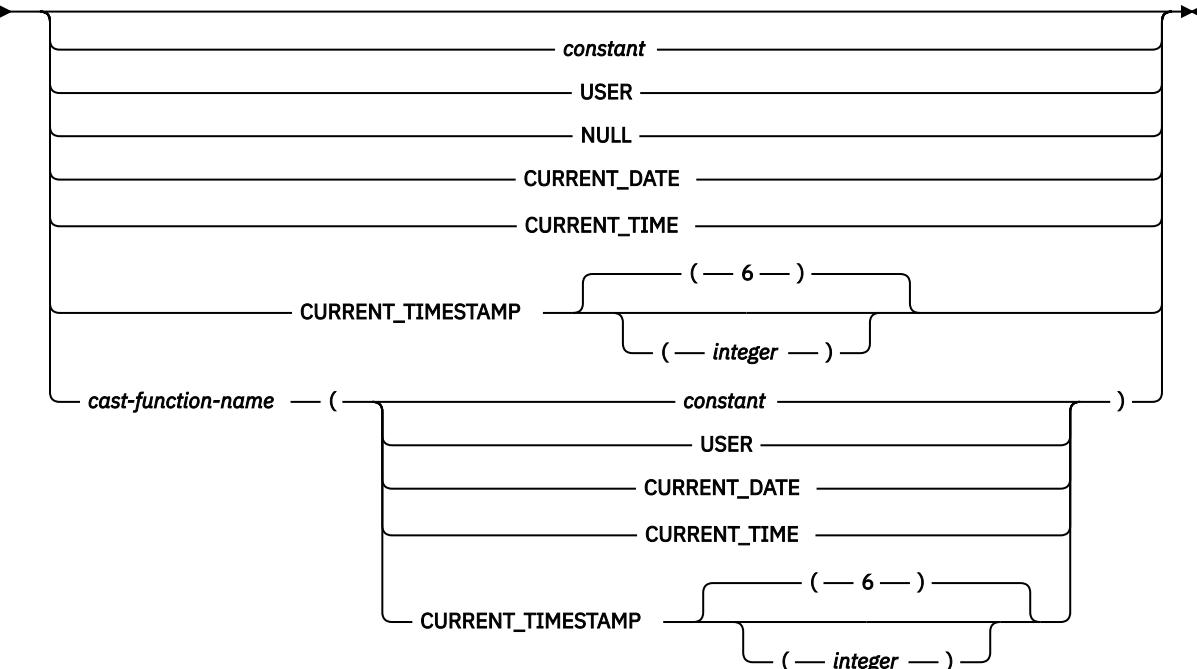

normalize-clause

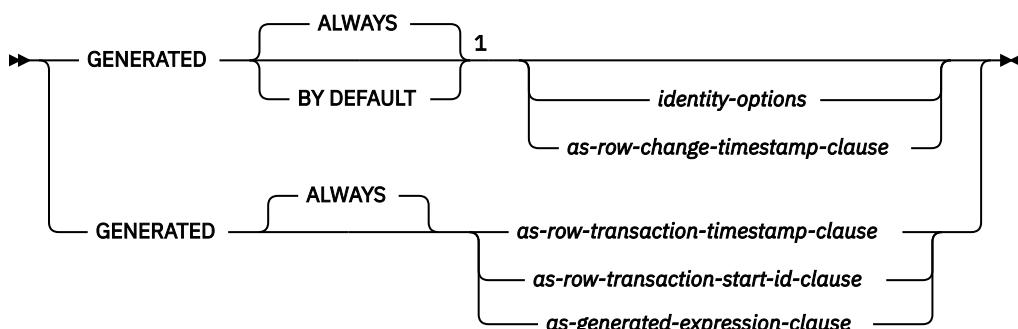

allocate-clause

►► ALLOCATE — (integer) ►►

default-clause

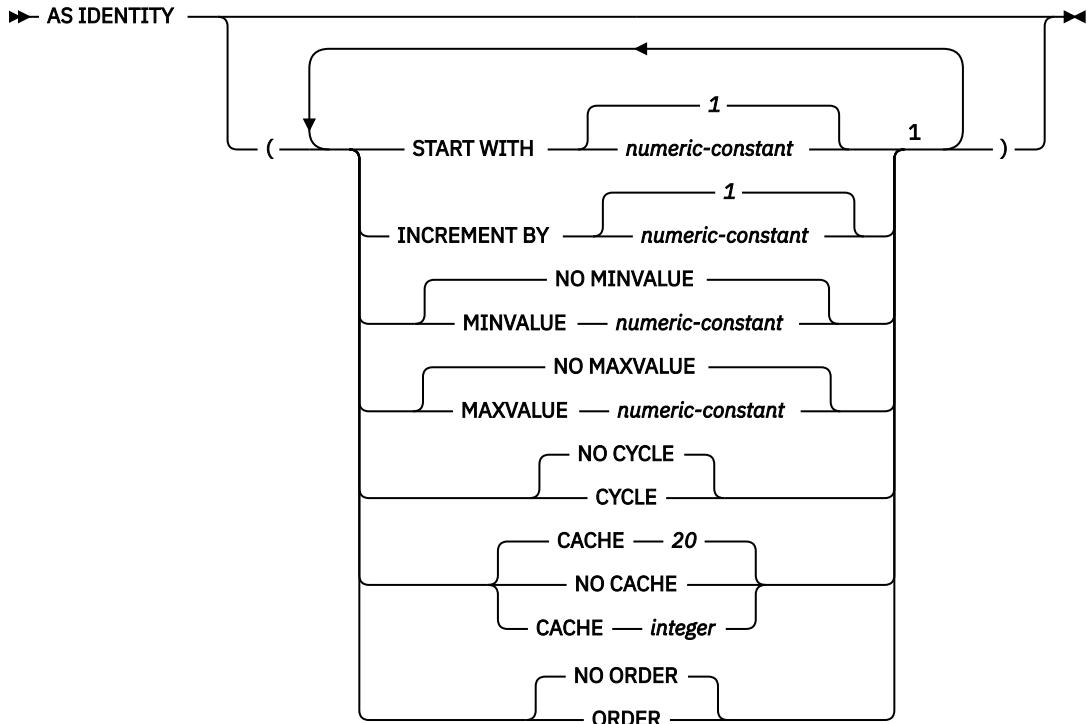

generated-clause

Notes:

¹ GENERATED can be specified only if the column has a ROWID data type (or a distinct type that is based on a ROWID data type), or the column is an identity column, or the column is a row change timestamp.

identity-options

Notes:

¹ The same clause must not be specified more than once.

Notes:

¹ The clauses can be specified in any order.

Description

table-name

Names the temporary table. The qualifier, if specified explicitly, must be SESSION, otherwise an error is returned. If the qualifier is not specified, it is implicitly defined to be SESSION. If a declared temporary table, or an index or view that is dependent on a declared temporary table already exists with the same name, an error is returned.

If a persistent table, view, index, or alias already exists with the same name and the schema name SESSION:

- The declared temporary table is still defined with SESSION.*table-name*. An error is not issued because the resolution of a declared temporary table name does not include a permanent library.
 - Any references to SESSION.*table-name* will resolve to the declared temporary table rather than to a permanent table, view, index, or alias with a name of SESSION.*table-name*.

The table will be created in library QTEMP.

FOR SYSTEM NAME *system-object-identifier*

Identifies the *system-object-identifier* of the table. *system-object-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *table-name* must not be a valid system object name.

column-definition

Defines the attributes of a column. There must be at least one column definition and no more than 8000 column definitions.

The sum of the row buffer byte counts of the columns must not be greater than 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740. Additionally, if a LOB or XML column is specified, the sum of the row data byte counts of the columns must not be greater than 3.5 gigabytes. For information about the byte counts of columns according to data type, see “[Maximum row sizes](#)” on page 991.

column-name

Names a column of the table. Do not qualify *column-name* and do not use the same name for more than one column of the table or for a system-column-name of the table.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see “[Rules for Column Name Generation](#)” on page 993.

data-type

Specifies the data type of the column.

built-in-type

Specifies a built-in data type. See “[CREATE TABLE](#)” on page 945 for a description of *built-in-type*.

A ROWID column or a DATALINK column with FILE LINK CONTROL cannot be specified for a declared temporary table.

distinct-type-name

Specifies that the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

DEFAULT

Specifies a default value for the column. This clause cannot be specified more than once in a *column-definition*. DEFAULT cannot be specified for the following types of columns because Db2 generates default values:

- an identity column (a column that is defined AS IDENTITY)
- a row change timestamp column
- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

For an XML column, the default is NULL unless NOT NULL is specified; in that case there is no default.

If a value is not specified following the DEFAULT keyword, then:

- if the column is nullable, the default value is the null value.
- if the column is not nullable, the default depends on the data type of the column:

Data type	Default value
Numeric	0
Fixed-length character or graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string length of 0
Date	The current date at the time of INSERT
Time	The current time at the time of INSERT
Timestamp	The current timestamp at the time of INSERT
Datalink	A value corresponding to DLVALUE(''URL'')
<i>distinct-type</i>	The default value of the corresponding source type of the distinct type.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

constant

Specifies the constant as the default for the column. The specified constant must represent a value that could be assigned to the column in accordance with the rules of assignment as described in “Assignments and comparisons” on page 83. A floating-point constant or decimal floating-point constant must not be used for a SMALLINT, INTEGER, DECIMAL, or NUMERIC column. A decimal constant must not contain more digits to the right of the decimal point than the specified scale of the column.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value of the column. The data type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register.

NULL

Specifies null as the default for the column. If NOT NULL is specified, DEFAULT NULL must not be specified within the same *column-definition*.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the column must be DATE or a distinct type based on a DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the column must be TIME or a distinct type based on a TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(*integer*)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the column must be TIMESTAMP or a distinct type based on a TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

cast-function-name

This form of a default value can only be used with columns defined as a strongly typed distinct type, BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME or TIMESTAMP data types. The following table describes the allowed uses of these *cast-functions*.

Data Type	Cast Function Name
Strongly typed distinct type N based on a BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
Strongly typed distinct type N based on a DATE, TIME, or TIMESTAMP	N (the user-defined cast function that was generated when N was created) ** or DATE, TIME, or TIMESTAMP *
Strongly typed distinct type N based on other data types	N (the user-defined cast function that was generated when N was created) **
BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
DATE, TIME, or TIMESTAMP	DATE, TIME, or TIMESTAMP *

Notes:

* The name of the function must match the name of the data type (or the source type of the distinct type) with an implicit or explicit schema name of QSYS2.

** The name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type.

constant

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. For BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, and TIMESTAMP functions, the constant must be a string constant.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the source type of the distinct type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the source type of the distinct type of the column must be DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the source type of the distinct type of the column must be TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(integer)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the source type of the distinct type of the column must be TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

If the value specified is not valid, an error is returned.

GENERATED

Specifies that the database manager generates values for the column. GENERATED may be specified if the column is to be considered one of the following types of columns:

- an identity column

- a row change timestamp column

GENERATED must be specified if the column is to be considered one of the following types of columns:

- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

It may also be specified if the data type of the column is a ROWID (or a distinct type that is based on a ROWID). Otherwise, it must not be specified. GENERATED must not be specified with *default-clause* in a column definition.

ALWAYS

Specifies that the database manager will always generate a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the recommended value.

BY DEFAULT

Specifies that the database manager will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For an identity column or row change timestamp column, the database manager inserts or updates a specified value but does not verify that it is a unique value for the column unless the identity column or row change timestamp column has a unique constraint or a unique index that solely specifies the identity column or row change timestamp column.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause. See the AS IDENTITY clause in “[CREATE TABLE](#)” on page 945 for the descriptions of the identity attributes.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp and the values will be generated by the database manager. The database manager generates a value for the column for each row as a row is inserted, and for every row in which any column is updated. The value generated for a row change timestamp column is a timestamp corresponding to the time of the insert or update of the row. If multiple rows are inserted with a single SQL statement, the value for the row change timestamp column may be different for each row to reflect when each row was inserted. The generated value is not guaranteed to be unique.

A table can have only one row change timestamp column. If *data-type* is specified, it must be a TIMESTAMP with a precision of 6 or a distinct type based on a TIMESTAMP with a precision of 6. A row change timestamp column cannot have a DEFAULT clause and must be NOT NULL.

AS ROW BEGIN

Specifies that the column contains timestamp data and that the values are generated by the database manager. The database manager generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same for each row.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are inserted or updated

within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period.

A table can have only one row-begin column. If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-begin column is not updatable.

AS ROW END

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated. The assigned value is TIMESTAMP '9999-12-30-00.00.000000000000'.

A row-end column is required as the second column of a SYSTEM_TIME period

A table can have only one row-end column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable and if there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table.

A table can have only one transaction-start-ID column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified it must be TIMESTAMP(12). A transaction-start-ID column cannot have a DEFAULT clause. A transaction-start-ID column is not updatable.

DATA CHANGE OPERATION

Specifies that the database manager generates a value for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The column will contain one of the following values:

I

insert operation

U

update operation

D

delete operation

If *data-type* is not specified, the column is defined as CHAR(1). If *data-type* is specified it must be CHAR(1). The column cannot have a DEFAULT clause or a field procedure.

special-register

Specifies that the value of a special register is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the special register at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

Special register	Data type for the column
CURRENT CLIENT_ACCTNG	VARCHAR(255)

Special register	Data type for the column
CURRENT CLIENT_APPLNAME	VARCHAR(255)
CURRENT CLIENT_PROGRAMID	VARCHAR(255)
CURRENT CLIENT_USERID	VARCHAR(255)
CURRENT CLIENT_WRKSTNNAME	VARCHAR(255)
CURRENT SERVER	VARCHAR(18)
SESSION_USER	VARCHAR(128)
USER	VARCHAR(18)

The column cannot have a DEFAULT clause or a field procedure.

built-in-global-variable

Specifies that the value of a built-in global variable is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the built-in global variable at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

Built-in global variable	Data type for the column
QSYS2.JOB_NAME	VARCHAR(28)
QSYS2.SERVER_MODE_JOB_NAME	VARCHAR(28)
SYSIBM.CLIENT_HOST	VARCHAR(255)
SYSIBM.CLIENT_IPADDR	VARCHAR(128)
SYSIBM.CLIENT_PORT	INTEGER
SYSIBM.PACKAGE_NAME	VARCHAR(128)
SYSIBM.PACKAGE_SCHEMA	VARCHAR(128)
SYSIBM.PACKAGE_VERSION	VARCHAR(64)
SYSIBM.ROUTINE_SCHEMA	VARCHAR(128)
SYSIBM.ROUTINE_SPECIFIC_NAME	VARCHAR(128)
SYSIBM.ROUTINE_TYPE	CHAR(1)

The column cannot have a DEFAULT clause or a field procedure.

FIELDPROC

Designates an *external-program-name* as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

constant

Specifies a parameter that is passed to the field procedure when it is invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or DATALINK or a distinct type based on a ROWID or DATALINK. The column must not be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The column must not have a default value of CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The column cannot be referenced in a check condition. If it is part of a foreign key, the corresponding parent key column must use the same field procedure. See [Embedded SQL programming topic collection](#) for an example of a field procedure.

NOT NULL

Prevents the column from containing null values. Omission of NOT NULL implies that the column can be null. NOT NULL is required for a row change timestamp column, a row-begin column, and a row-end column.

NOT HIDDEN

Indicates the column is included in implicit references to the table in SQL statements. This is the default.

IMPLICITLY HIDDEN

Indicates the column is not visible in SQL statements unless it is referred to explicitly by name. For example, SELECT * does not include any hidden columns in the result. A table must contain at least one column that is not IMPLICITLY HIDDEN.

datalink-options

Specifies the options associated with a DATALINK data type.

LINKTYPE URL

Defines the type of link as a Uniform Resource Locator (URL).

NO LINK CONTROL

Specifies that there will not be any check made to determine that the linked files exist. Only the syntax of the URL will be checked. There is no database manager control over the linked files.

period-definition**PERIOD FOR**

Defines a period for the table.

SYSTEM_TIME (*begin-column-name*, *end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period.

begin-column-name

Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table. *begin-column-name* must not be the same as *end-column-name*. *begin-column-name* must be defined as AS ROW BEGIN.

end-column-name

Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to *end-column-name* in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table. *end-column-name* must be defined as AS ROW END.

LIKE***table-name or view-name***

Specifies that the columns defined in the specified table or view are included in this table. The *table-name or view-name* specified in a LIKE clause must identify the table or view that already exists at the application server.

The use of LIKE is an implicit definition of n columns, where n is the number of columns in the identified table or view. The implicit definition includes the following attributes of the n columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID

If the LIKE clause is specified immediately following the *table-name* and not enclosed in parenthesis, the following column attributes are also included, otherwise they are not included (the default value, identity, row change timestamp, and hidden attributes can also be controlled by using the *copy-options*):

- Default value, if a *table-name* is specified (*view-name* is not specified)
- Identity attributes
- Nullability
- Hidden attributes
- Row change timestamp attribute
- Column heading and text (see “[LABEL](#)” on page 1211)

If *table-name* contains a row change timestamp column, row-begin column, row-end column, transaction-start-ID column, or generated expression column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.

If the specified table or view is a non-SQL created physical file or logical file, any non-SQL attributes are removed. For example, the date and time format will be changed to ISO.

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include a primary key or foreign key from a table. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

as-result-table

column-name

Names a column of the table. Do not qualify *column-name* and do not use the same name for more than one column of the table or for a system-column-name of the table.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see “[Rules for Column Name Generation](#)” on page 993.

select-statement

Specifies that the columns of the table are to have the same name and description as the columns that would appear in the derived result table of the *select-statement* if the *select-statement* were to be executed. The use of AS *select-statement* is an implicit definition of n columns for the table, where n is the number of columns that would result from the *select-statement*. The implicit definition includes the following attributes of the n columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- Nullability
- Column heading and text (see “[LABEL](#)” on page 1211)

The following attributes are not included (some attributes can be included by using the *copy-options*):

- Default value
- Hidden attribute
- Identity attributes
- Row change timestamp attribute
- Row-begin, row-end, and transaction-start-ID attribute
- Generated expression attribute

The implicit definition does not include any other optional attributes of the tables or views referenced in the *select-statement*.

The implicitly defined columns of the table inherit the names of the columns from the result table of the *select-statement*. Therefore, a column name must be specified in the *select-statement* or in the column name list for all result columns. For result columns that are derived from expressions, constants, and functions, the *select-statement* must include the AS column-name clause immediately after the result column or a name must be specified in the column list preceding the *select-statement*.

The *select-statement* must not refer to variables or include parameter markers (question marks). The *select-statement* must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.

If the *select-statement* contains an *isolation-clause* the isolation level specified in the *isolation-clause* applies to the entire SQL statement.

WITH DATA

Specifies that the *select-statement* is executed. After the table is created, the result table rows of the *select-statement* are automatically inserted into the table.

WITH NO DATA

Specifies that the *select-statement* is not executed. Therefore, there is no result table with a set of rows with which to automatically populate the table.

copy-options

INCLUDING IDENTITY COLUMN ATTRIBUTES or EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies whether identity column attributes are inherited.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table inherits the identity attribute, if any, of the columns resulting from *select-statement*, *table-name*, or *view-name*. In general, the identity attribute is copied if the element of the corresponding column in the table, view, or *select-statement* is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the identity attribute. If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS *select-statement* clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the *select-statement* includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the *select-statement* includes multiple identity columns (that is, a join returned more than one identity column).
- The identity column is included in an expression in the select list.
- The *select-statement* includes a set operation (UNION or INTERSECT).

If INCLUDING IDENTITY is not specified, the table will not have an identity column.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table does not inherit the identity attribute, if any, of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

EXCLUDING COLUMN DEFAULTS or INCLUDING COLUMN DEFAULTS or USING TYPE DEFAULTS

Specifies whether column defaults are inherited.

EXCLUDING COLUMN DEFAULTS

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on INSERT for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that the table inherits the default values of the columns resulting from the *select-statement*, *table-name*, or *view-name*. A default value is the value assigned to a column when a value is not specified on an INSERT.

Do not specify INCLUDING COLUMN DEFAULTS, if you specify USING TYPE DEFAULTS.

If INCLUDING COLUMN DEFAULTS is not specified, the default values are not inherited.

USING TYPE DEFAULTS

Specifies that the default values for the table depend on the data type of the columns that result from the *select-statement*, *table-name*, or *view-name*. If the column is nullable, then the default value is the null value. Otherwise, the default value is as follows:

Data type	Default value
Numeric	0
Fixed-length character or graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string length of 0
Date	The current date at the time of INSERT
Time	The current time at the time of INSERT
Timestamp	The current timestamp at the time of INSERT
Datalink	A value corresponding to DLVALUE(''URL'')
<i>distinct-type</i>	The default value of the corresponding source type of the distinct type.

Do not specify USING TYPE DEFAULTS if INCLUDING COLUMN DEFAULTS is specified.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES or EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies whether implicitly hidden columns are inherited.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table inherits implicitly hidden columns from *select-statement*, *table-name*, or *view-name* and those columns will be defined with the implicitly hidden attribute in the new table.

If INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES is not specified, the table will not have any implicitly hidden columns.

EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table does not inherit implicitly hidden columns from the *fullselect*, *table-name*, or *view-name*.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies whether the row change timestamp attribute is inherited.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table inherits the row change timestamp attribute, if any, of the columns resulting from *select-statement*, *table-name*, or *view-name*. In general, the row change timestamp attribute is copied if the element of the corresponding column in the table, view, or *select-*

statement is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the row change timestamp attribute. If the INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES clause is specified with the AS *select-statement* clause, the columns of the new table do not inherit the row change timestamp in the following cases:

- The select list of the *select-statement* includes multiple instances of a row change timestamp column name (that is, selecting the same column more than once).
- The select list of the *select-statement* includes multiple row change timestamp columns (that is, a join returned more than one row change timestamp column).
- The row change timestamp column is included in an expression in the select list.
- The *select-statement* includes a set operation (UNION or INTERSECT).

If INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES is not specified, the table will not have a row change timestamp column.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table does not inherit the row change timestamp attribute, if any, of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

WITH REPLACE

Specifies that, in the case that a declared temporary table already exists with the specified name, the existing table is replaced with the temporary table defined by this statement (and all rows of the existing table are deleted).

When WITH REPLACE is not specified, then the name specified must not identify a declared temporary table that already exists in the current session.

ON COMMIT

Specifies the action taken on the declared temporary table when a COMMIT operation is performed. The default is DELETE ROWS.

The ON COMMIT clause does not apply if the declared temporary table is opened under isolation level No Commit (NC) or if a COMMIT HOLD operation is performed.

DELETE ROWS

All rows of the table will be deleted if no WITH HOLD cursor is open on the table.

PRESERVE ROWS

Rows of the table will be preserved.

NOT LOGGED

Changes to the table are not logged, including creation of the table. When a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation is performed and the table was changed in the unit of work (or savepoint), the changes are not rolled back. If the table was created in the unit of work (or savepoint), then that table will be dropped. If the table was dropped in the unit of work (or savepoint) then the table will be restored, but with no rows.

ON ROLLBACK

Specifies the action taken on the declared temporary table when a ROLLBACK operation is performed.

The ON ROLLBACK clause does not apply if the declared temporary table was opened under isolation level No Commit (NC) or if a ROLLBACK HOLD operation is performed.

DELETE ROWS

All rows of the table will be deleted. This is the default.

PRESERVE ROWS

Rows of the table will be preserved.

RCDFMT *format-name*

An unqualified name that designates the IBM i record format name of the table. A *format-name* is a system identifier.

If a record format name is not specified, the *format-name* is the same as the *system-object-name* of the table.

media-preference

Specifies the preferred storage media for the table.

UNIT ANY

No storage media is preferred. Storage for the table will be allocated from any available storage media.

UNIT SSD

Solid state disk storage media is preferred. Storage for the table may be allocated from solid state disk storage media, if available.

KEEP IN MEMORY

Specifies whether the data for the table should be brought into a main storage pool when the data is used in a query.

NO

The data will not be brought into a main storage pool.

YES

The data will be brought into a main storage pool.

Notes

Instantiation, scope, and termination: Let P denote an application process and let T be a declared temporary table in an application program in P:

- When a program in P issues a DECLARE GLOBAL TEMPORARY TABLE statement, an empty instance of T is created.
- Any program in P can reference T, and any of those references is a reference to that same instance of T. (If a DECLARE GLOBAL TEMPORARY statement is specified within a compound statement of an SQL function, SQL procedure, or trigger; the scope of the declared temporary table is the application process and not the compound statement.)

If T was declared at a remote server, the reference to T must use the same connection that was used to declare T and that connection must not have been terminated after T was declared. When the connection to the database server at which T was declared terminates, T is dropped.

- If T is defined with the ON COMMIT DELETE ROWS clause, when a commit operation terminates a unit of work in P and no program in P has a WITH HOLD cursor open that is dependent on T, all rows are deleted.
- If T is defined with the ON ROLLBACK DELETE ROWS clause, when a rollback operation terminates a unit of work in P, all rows are deleted.
- When the application process that declared T terminates, T is dropped.

Temporary table ownership: The *owner* of the table is the user profile of the thread executing the statement.

Temporary table authority: When a declared temporary table is defined, PUBLIC implicitly is granted all table privileges on the table and authority to drop the table.

Referring to a declared temporary table in other SQL statements: Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, the table must be implicitly or explicitly qualified with SESSION.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, the database manager assumes that you are not referring to a declared temporary table. The database manager resolves such table references to a permanent table.

Restrictions on the use of declared temporary tables:

- Declared temporary tables cannot be specified in an ALTER TABLE, COMMENT, CREATE ALIAS, GRANT, LABEL, LOCK, RENAME, or REVOKE statement.
- Declared temporary tables cannot be specified as the parent table in referential constraints
- If a declared temporary table is referenced in a CREATE INDEX or CREATE VIEW statement, the index or view must be created in SESSION (or library QTEMP).

Creating a table using a remote select-statement: The *select-statement* for an *as-result-table* can refer to tables on a different server than where the table is being created. This can be done by using a three-part object name or an alias that is defined to reference a three-part name of a table or view. The result of the *select-statement* cannot contain a column that has a field procedure defined. If the remote server is Db2 for LUW or Db2 for z/OS, *copy-options* are not allowed. If the remote server is Db2 for LUW, a column list should be explicitly specified before the AS keyword.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- INLINE LENGTH is a synonym for ALLOCATE.
- DEFINITION ONLY is a synonym for WITH NO DATA

Examples

Example 1: Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
(EMPNO    CHAR(6)      NOT NULL,
 SALARY    DECIMAL(9, 2),
 BONUS     DECIMAL(9, 2),
 COMM      DECIMAL(9, 2))
ON COMMIT PRESERVE ROWS
```

Example 2: Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
  LIKE USER1.EMPTAB
  INCLUDING IDENTITY
  ON COMMIT PRESERVE ROWS
```

In the above example, the database manager uses SESSION as the implicit qualifier for TEMPTAB1.

DECLARE PROCEDURE

The DECLARE PROCEDURE statement defines an external procedure.

Invocation

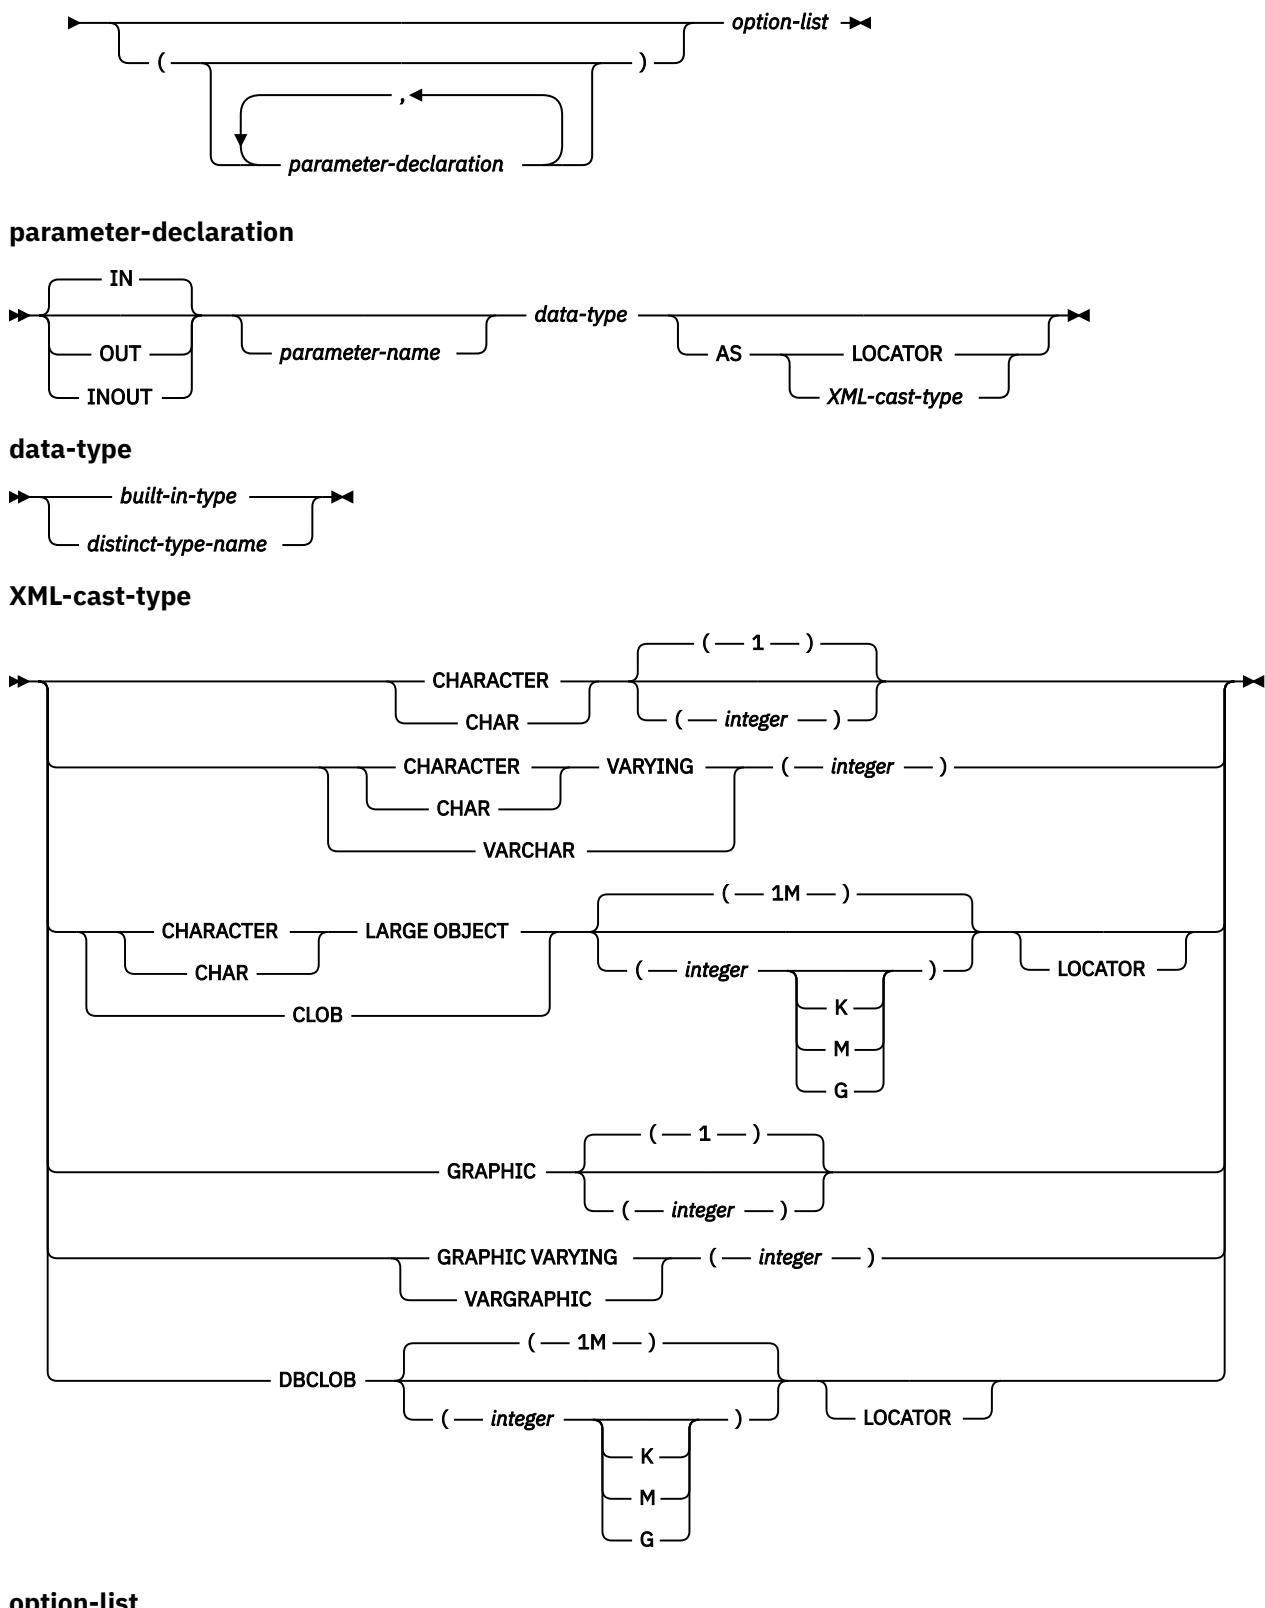

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in REXX.

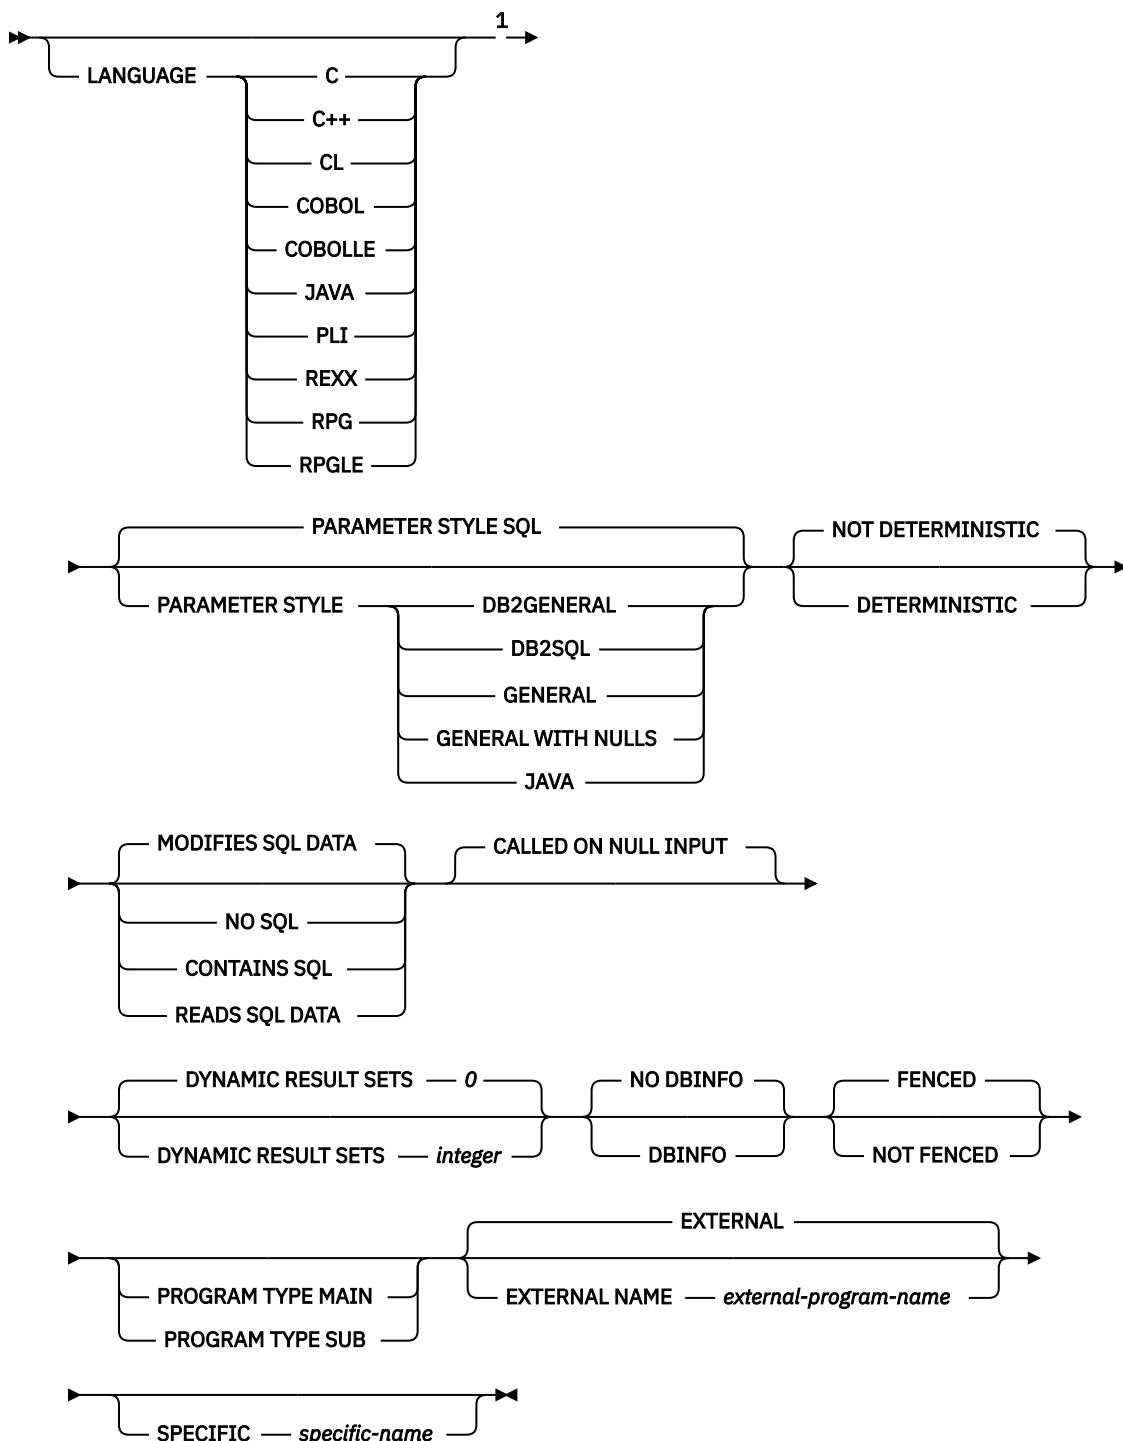

Authorization

None required.

Syntax

► DECLARE — *procedure-name* — PROCEDURE ►

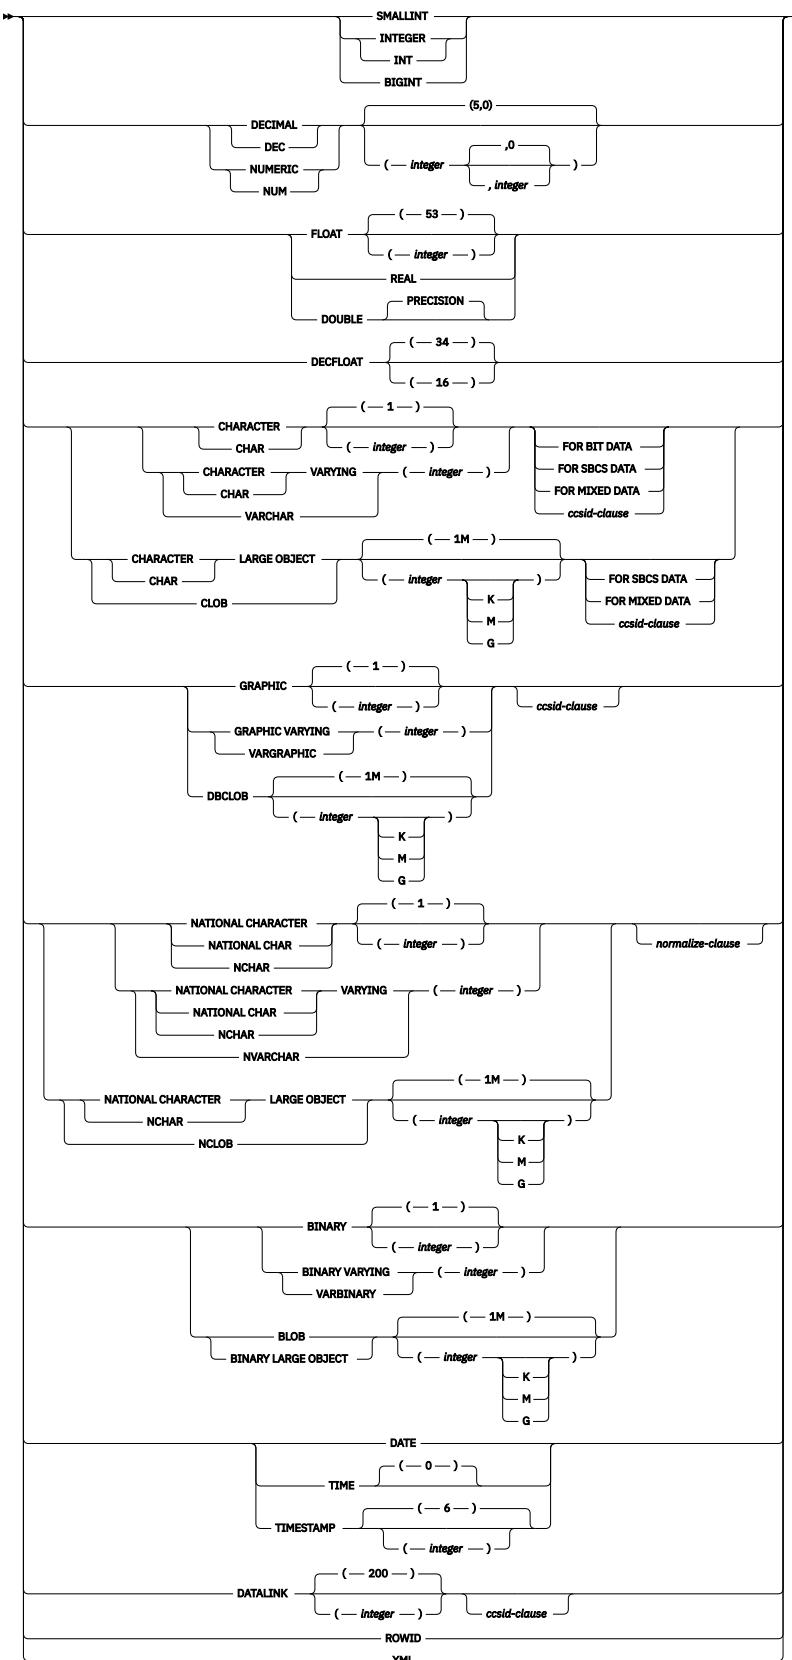

Notes:

¹ The optional clauses can be specified in a different order.

built-in-type

ccsid-clause

►► CCSID — *integer* —►►
 —►► *normalize-clause* —►►

normalize-clause

Description

procedure-name

Names the procedure. The name must not be the same as the name of another procedure declared in your source program.

(parameter-declaration,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. Although not required, you can give each parameter a name.

The maximum number of parameters allowed in CREATE PROCEDURE depends on the type of language and the parameter style:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs and REXX,
 - If PARAMETER STYLE GENERAL is specified the maximum is 255.
 - If PARAMETER STYLE GENERAL WITH NULLS is specified the maximum is 254.
 - If PARAMETER STYLE SQL is specified the maximum is 254.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

IN

Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned.¹⁰²

OUT

Identifies the parameter as an output parameter that is returned by the procedure.

A DataLink or a distinct type based on a DataLink may not be specified as an output parameter.

INOUT

Identifies the parameter as both an input and output parameter for the procedure.

A DataLink or a distinct type based on a DataLink may not be specified as an input and output parameter.

parameter-name

Names the parameter. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter.

The data type must be valid for the language specified in the language clause. All data types are valid for SQL procedures. DataLinks are not valid for external procedures. For more information about data types, see “CREATE TABLE” on page 945, and the [SQL Programming](#) topic collection.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is called.

Any parameter that has an XML type must specify the *XML-cast-type* clause.

¹⁰² When the language type is REXX, all parameters must be input parameters.

AS LOCATOR

Specifies that the parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

AS XML-*cast-type*

Specifies the data type passed to the procedure for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the containing program, module, or service program is created according to the SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See “[XML Values](#)” on page 75 for a description of this option.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of result sets that can be returned from the procedure. *integer* must be greater than or equal to zero and less than 32768. If zero is specified, no result sets are returned. If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement.

For more information about result sets, see “[SET RESULT SETS](#)” on page 1324.

LANGUAGE

Specifies the language that the external program is written in. The language clause is required if the external program is a REXX procedure.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program. If the program attribute information associated with the program does not identify a recognizable language, then the language is assumed to be C.

C

The external program is written in C.

C++

The external program is written in C++.

CL

The external program is written in CL.

COBOL

The external program is written in COBOL.

COBOLLE

The external program is written in ILE COBOL.

JAVA

The external program is written in JAVA.

PLI

The external program is written in PL/I.

REXX

The external program is a REXX procedure.

RPG

The external program is written in RPG.

RPGLE

The external program is written in ILE RPG.

PARAMETER STYLE

Specifies the conventions used for passing parameters to and returning the values from procedures:

SQL

Specifies that in addition to the parameters on the CALL statement, several additional parameters are passed to the procedure. The parameters are defined to be in the following order:

- The first N parameters are the parameters that are specified on the DECLARE PROCEDURE statement.
- N parameters for indicator variables for the parameters.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the procedure. The SQLSTATE returned is assigned by the external program.

The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.

- A VARCHAR(517) input parameter for the fully qualified procedure name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.

The following additional parameter may be passed as the last parameter:

- A parameter for the dbinfo structure, if DBINFO was specified on the CREATE PROCEDURE statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

PARAMETER STYLE SQL cannot be used with LANGUAGE JAVA.

DB2GENERAL

Specifies that the procedure will use a parameter passing convention that is defined for use with Java methods.

PARAMETER STYLE DB2GENERAL can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#) topic collection.

GENERAL

Specifies that the procedure will use a parameter passing mechanism where the procedure receives the parameters specified on the CALL. Additional arguments are not passed for indicator variables.

PARAMETER STYLE GENERAL cannot be used with LANGUAGE JAVA.

GENERAL WITH NULLS

Specifies that in addition to the parameters on the CALL statement as specified in GENERAL, another argument is passed to the procedure. This additional argument contains an indicator array with an element for each of the parameters of the CALL statement. In C, this would be an array of short INTs. For more information about how the indicators are handled, see the [SQL Programming](#) topic collection.

PARAMETER STYLE GENERAL WITH NULLS cannot be used with LANGUAGE JAVA.

JAVA

Specifies that the procedure will use a parameter passing convention that conforms to the Java language and SQLJ Routines specification. INOUT and OUT parameters will be passed as single entry arrays to facilitate returning values. For increased portability, you should write Java procedures that use the PARAMETER STYLE JAVA conventions.

PARAMETER STYLE JAVA can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#) topic collection.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see [SQL Programming](#). For Java routines, see [IBM Developer Kit for Java](#).

SPECIFIC *specific-name*

Specifies a qualified or unqualified name that uniquely identifies the procedure. The *specific-name*, including the implicit or explicit qualifier, must be the same as the *procedure-name*.

If no qualifier is specified, the implicit or explicit qualifier of the *procedure-name* is used. If a qualifier is specified, the qualifier must be the same as the explicit or implicit qualifier of the *procedure-name*.

If *specific-name* is not specified, it is the same as the procedure name.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

NOT DETERMINISTIC

The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DETERMINISTIC

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies which SQL statements, if any, may be executed in the procedure or any routine called from this procedure. The default is MODIFIES SQL DATA. See Appendix B, “Characteristics of SQL statements,” on page 1421 for a detailed list of the SQL statements that can be executed under each data access indication.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that SQL statements that do not modify SQL data can be included in the procedure.

CONTAINS SQL

Specifies that SQL statements that neither read nor modify SQL data can be executed by the procedure.

NO SQL

Specifies that the procedure cannot execute any SQL statements.

CALLED ON NULL INPUT

Specifies that the function is to be invoked, if any, or all, argument values are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

FENCED or NOT FENCED

This parameter is allowed for compatibility with other products and is not used by Db2 for i.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB

This parameter is allowed for compatibility with other products. It indicates whether the routine's external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN

Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

PROGRAM TYPE SUB

Specifies that the procedure executes as a procedure in a service program. The external program must be a *SRVPGM object.

DBINFO

Specifies that the database manager should pass a structure containing status information to the procedure. Table 98 on page 1073 contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE DB2SQL.

Table 98. DBINFO fields

Field	Data Type	Description
Relational database	VARCHAR(128)	The name of the current server.
Authorization ID	VARCHAR(128)	The run-time authorization ID.
CCSID Information	INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER INTEGER CHAR(8)	<p>The CCSID information of the job. Three sets of three CCSIDs are returned. The following information identifies the three CCSIDs in each set:</p> <ul style="list-style-type: none"> • SBCS CCSID • DBCS CCSID • Mixed CCSID <p>Following the three sets of CCSIDs is an integer that indicates which set of three sets of CCSIDs is applicable and eight bytes of reserved space.</p> <p>Each set of CCSIDs is for a different encoding scheme (EBCDIC, ASCII, and Unicode).</p> <p>If a CCSID is not explicitly specified for a parameter on the CREATE PROCEDURE statement, the input string is assumed to be encoded in the CCSID of the job at the time the procedure is executed. If the CCSID of the input string is not the same as the CCSID of the parameter, the input string passed to the external procedure will be converted before calling the external program.</p>
Target Column	VARCHAR(128) VARCHAR(128) VARCHAR(128)	Not applicable for a call to a procedure.
Version and release	CHAR(8)	The version, release, and modification level of the database manager.
Platform	INTEGER	The server's platform type.

EXTERNAL NAME *external-program-name*

Specifies the program that will be executed when the procedure is called by the CALL statement. The program name must identify a program that exists at the application server. The program cannot be an ILE service program.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

If *external-program-name* is not specified, the external program name is assumed to be the same as the procedure name.

Notes

DECLARE PROCEDURE scope: The scope of the *procedure-name* is the source program in which it is defined; that is, the program submitted to the precompiler. Thus, a program called from another separately compiled program or module will not use the attributes from a DECLARE PROCEDURE statement in the calling program.

DECLARE PROCEDURE rules: The DECLARE PROCEDURE statement should precede all CALL statements that reference that procedure.

The DECLARE PROCEDURE statement only applies to static CALL statements. It does not apply to any dynamically prepared CALL statements or a CALL statement where the procedure name is identified by a variable.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords PARAMETER STYLE DB2SQL can be used as a synonym for PARAMETER STYLE SQL.

Example

Declare an external procedure PROC1 in a C program. When the procedure is called using the CALL statement, a COBOL program named PGM1 in library LIB1 will be called.

```
EXEC SQL
DECLARE PROC1 PROCEDURE
      (CHAR(10), CHAR(10))
      EXTERNAL NAME LIB1.PGM1
      LANGUAGE COBOL GENERAL;

EXEC SQL
CALL PROC1 ('FIRSTNAME ','LASTNAME '');
```

DECLARE STATEMENT

The DECLARE STATEMENT statement is used for program documentation. It declares names that are used to identify prepared SQL statements.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. This statement is not allowed in Java or REXX.

Authorization

None required.

Syntax

```
►► DECLARE [statement-name] STATEMENT ►►
```

Description

statement-name

Lists one or more names that are used in your program to identify prepared SQL statements.

Example

This example shows the use of the DECLARE STATEMENT statement in a C program.

```

EXEC SQL INCLUDE SQLDA;
void main ()
{
  EXEC SQL BEGIN DECLARE SECTION ;
  char src_stmt[32000];
  char sqllda[32000];
  EXEC SQL END DECLARE SECTION ;
  EXEC SQL INCLUDE SQLCA ;

  strcpy(src_stmt,"SELECT DEPTNO, DEPTNAME, MGRNO \
    FROM DEPARTMENT \
    WHERE ADMRDEPT = 'A00'" );

  EXEC SQL DECLARE OBJ_STMT STATEMENT;
  (Allocate storage from SQLDA)

  EXEC SQL DECLARE C1 CURSOR FOR OBJ_STMT;

  EXEC SQL PREPARE OBJ_STMT FROM :src_stmt;
  EXEC SQL DESCRIBE OBJ_STMT INTO :sqllda;
  (Examine SQLDA) (Set SQLDATA pointer addresses)

  EXEC SQL OPEN C1;
  while (strncmp(SQLSTATE, "00000", 5) )
  {
    EXEC SQL FETCH C1 USING DESCRIPTOR :sqllda;
    (Print results)
  }

  EXEC SQL CLOSE C1;
  return;
}

```

DECLARE VARIABLE

The DECLARE VARIABLE statement is used to assign a subtype or CCSID other than the default to a host variable.

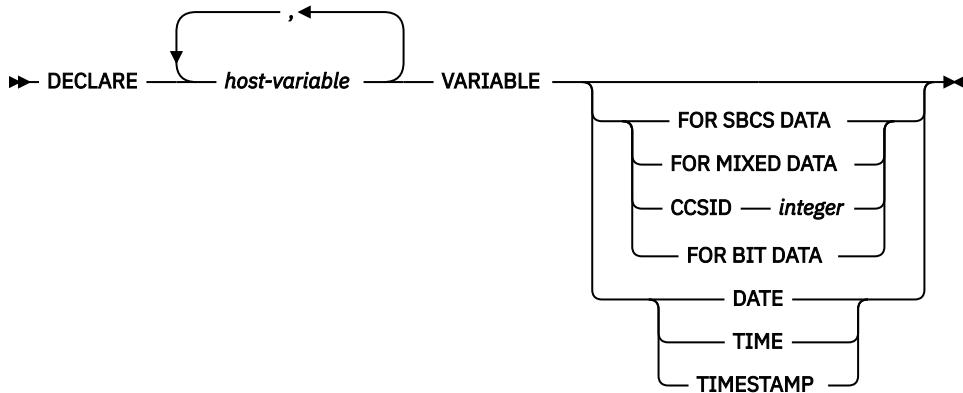

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

Description

host-variable

Names a character, graphic, or XML string host variable defined in the program. An indicator variable cannot be specified for the host-variable. The host-variable definition may either precede or follow a DECLARE VARIABLE statement that refers to that variable.

FOR BIT DATA

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535. FOR BIT DATA cannot be specified for graphic or XML host-variables.

FOR SBCS DATA

Specifies that the values of the host variable contain SBCS (single-byte character set) data. FOR SBCS DATA is the default if the CCSID attribute of the job at the application requester is not DBCS-capable or if the length of the host variable is less than 4. The CCSID of FOR SBCS DATA is determined by the CCSID attribute of the job at the application requester. FOR SBCS DATA cannot be specified for graphic or XML host-variables.

FOR MIXED DATA

Specifies that the values of the host variable contain both SBCS data and DBCS data. FOR MIXED DATA is the default if the CCSID attribute of the job at the application requester is DBCS-capable and the length of the host variable is greater than 3. The CCSID of FOR DBCS DATA is determined by the CCSID attribute of the job at the application requester. FOR MIXED DATA cannot be specified for graphic or XML host-variables.

CCSID integer

Specifies that the values of the host variable contain data of CCSID integer. If the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a mixed data CCSID, the host variable is mixed data. For character host variables, the CCSID specified must be an SBCS or mixed CCSID.

If the variable has a graphic string data type, the CCSID specified must be a DBCS, UTF-16, or UCS-2 CCSID. For a list of valid CCSIDs, see [Appendix E, “CCSID values,” on page 1455](#). Consider specifying CCSID 1200 or 13488 to indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the graphic string variable will be the associated DBCS CCSID for the job.

If the variable has an XML data type, the CCSID specified must be an SBCS, mixed, or Unicode CCSID. The CCSID must be compatible with the XML AS datatype. If a CCSID is not specified, the CCSID value as specified by the SQL_XML_DATA_CCSID QAQQINI setting is used. See [“XML Values” on page 75](#) for more information.

For file reference variables, the CCSID specifies the CCSID of the path and file name, not the data within the file.

DATE

Specifies that the values of the host variable contain data that is a date.

TIME

Specifies that the values of the host variable contain data that is a time.

TIMESTAMP

Specifies that the values of the host variable contain data that is a timestamp.

Notes

Placement restrictions: The DECLARE VARIABLE statement can be specified anywhere in an application program that SQL statements are valid with the following exceptions:

- If the host language is COBOL or RPG, the DECLARE VARIABLE statement must occur before an SQL statement that refers to a host variable specified in the DECLARE VARIABLE statement.
- If DATE, TIME, or TIMESTAMP is specified for a NUL-terminated character string in C, the length of the C declaration will be reduced by one.

Precompiler rules: The following situations result in an error message during precompile:

- A reference is made to a variable that does not exist.
- A reference is made to a numeric variable.
- A reference is made to a variable that has been referred to already.
- A reference is made to a variable that is not unique.
- A reference is made to an ILE RPG variable that is defined as UCS-2.
- A reference is made to an ILE COBOL variable that is defined as NATIONAL.
- The DECLARE VARIABLE statement occurs after an SQL statement where the SQL statement and the DECLARE VARIABLE statement refer to the same variable.
- The FOR BIT DATA, FOR SBCS DATA, or FOR MIXED DATA clause is specified for a graphic or XML host variable.
- A SBCS or mixed CCSID is specified for a graphic host variable.
- A DBCS, UTF-16, or UCS-2 CCSID is specified for a character host variable.
- A DBCS CCSID is specified for an XML host variable.
- DATE, TIME, or TIMESTAMP is specified for a host variable that is not character.
- The length of a host variable used for DATE, TIME, or TIMESTAMP is not long enough for the minimum date, time, or timestamp value.

Example

In this example, declare C program variables *fred* and *pete* as mixed data, and *jean* and *dave* as SBCS data with CCSID 37.

```
void main ()
{
    EXEC SQL BEGIN DECLARE SECTION;
    char fred[10];
    EXEC SQL DECLARE :fred VARIABLE FOR MIXED DATA;

    decimal(6,0) mary;
    char pete[4];
    EXEC SQL DECLARE :pete VARIABLE FOR MIXED DATA;

    char jean[30];
    char dave[9];
    EXEC SQL DECLARE :jean, :dave VARIABLE CCSID 37;
    EXEC SQL END DECLARE SECTION;
    EXEC SQL INCLUDE SQLCA;
    ...
}
```

DELETE

The DELETE statement deletes rows from a table or view. Deleting a row from a view deletes the row from the table on which the view is based if no INSTEAD OF DELETE trigger is defined for this view. If such a trigger is defined, the trigger will be activated instead.

There are two forms of this statement:

- The *Searched* DELETE form is used to delete one or more rows (optionally determined by a search condition).
- The *Positioned* DELETE form is used to delete exactly one row (as determined by the current position of a cursor).

Invocation

A Searched DELETE statement can be embedded in an application program or issued interactively. A Positioned DELETE must be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table or view identified in the statement:
 - The DELETE privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

If the *search-condition* in a Searched DELETE contains a reference to a column of the table or view, then the privileges held by the authorization ID of the statement must also include one of the following:

- The SELECT privilege on the table or view
- Database administrator authority

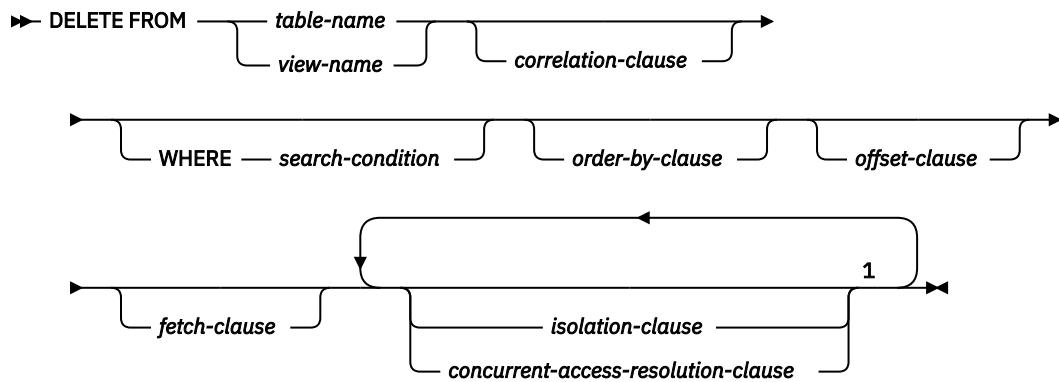

If *search-condition* includes a subquery, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For each table or view identified in the subquery:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

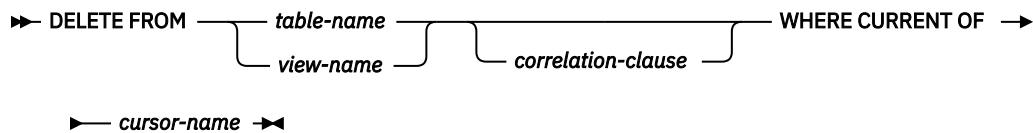

Searched DELETE:

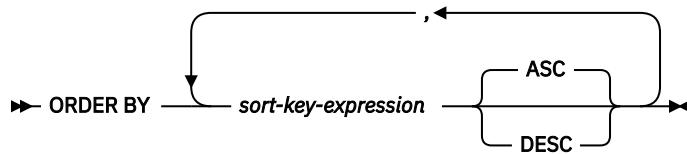

Notes:

¹ The same clause must not be specified more than once.

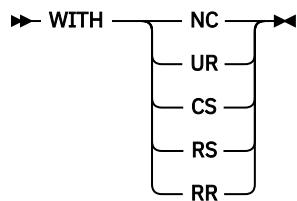

Positioned DELETE:

order-by-clause

isolation-clause

Description

FROM *table-name* or *view-name*

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the current server, but it must not identify a catalog table, a view of a catalog table, or a view that is not deletable. For an explanation of deletable views, see [“CREATE VIEW” on page 1029](#).

correlation-clause

Specifies an alternate name that can be used within the *search-condition* to designate the table or view. For an explanation of *correlation-clause*, see [Chapter 6, “Queries,” on page 597](#). For an explanation of *correlation-name*, see [“Correlation names” on page 123](#).

WHERE

Specifies the rows to be deleted. The clause can be omitted, or a *search-condition* or *cursor-name* can be specified. If the clause is omitted, all rows of the table or view are deleted.

search-condition

Is any search condition as described in [“Search conditions” on page 208](#). Each *column-name* in the *search-condition*, other than in a subquery, must identify a column of the table or view.

The *search-condition* is applied to each row of the table or view and the deleted rows are those for which the result of the *search-condition* is true.

If the *search-condition* contains a subquery, the subquery can be thought of as being executed each time the *search condition* is applied to a row, and the results used in applying the *search condition*. In actuality, a subquery with no correlated references may be executed only once, whereas a subquery with a correlated reference may have to be executed once for each row.

If a subquery refers to the object table of the DELETE statement or a dependent table with a delete rule of CASCADE, SET NULL, or SET DEFAULT, the subquery is completely evaluated before any rows are deleted.

CURRENT OF cursor-name

Identifies the cursor to be used in the delete operation. The *cursor-name* must identify a declared cursor as explained in the Notes for the DECLARE CURSOR statement.

The table or view identified must also be specified in the FROM clause of the *select-statement* of the cursor and the cursor must be deletable. For an explanation of deletable cursors, see “[DECLARE CURSOR](#)” on page 1037.

The DECLARE CURSOR statement must not have a period-specification for the table or view used by the delete statement.

When the DELETE statement is executed, the cursor must be positioned on a row; that row is the one deleted. After the deletion, the cursor is positioned before the next row of its result table. If there is no next row, the cursor is positioned after the last row.

order-by-clause

Specifies the order of the rows for application of the *offset-clause* and *fetch-clause*. An *order-by-clause* should be specified to ensure a predictable order for determining the set of rows to be deleted based on the *offset-clause* and *fetch-clause*.

sort-key-expression

An expression that specifies the value that is to be used to order the rows that qualify for the delete operation. If a single *sort-key-expression* is identified, the rows are ordered by the values of that *sort-key-expression*. If more than one *sort-key-expression* is identified, the rows are ordered by the values of the first *sort-key-expression*, then by the values of the second *sort-key-expression*, and so on.

The result of the *sort-key-expression* must not be DATALINK or XML.

ASC

Uses the values of the *sort-key-expression* in ascending order. This is the default.

DESC

Uses the values of the *sort-key-expression* in descending order.

Ordering is performed in accordance with the comparison rules described in [Chapter 2, “Language elements,” on page 43](#). The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key-expression* have an arbitrary order. If you do not specify ORDER BY, the rows to be deleted have an arbitrary order.

offset-clause

Limits the effect of the delete by skipping a subset of the qualifying rows. For more information on the *offset-clause*, see “[offset-clause](#)” on page 634.

fetch-clause

Limits the effect of the delete to a subset of the qualifying rows. For more information on the *fetch-clause*, see “[fetch-clause](#)” on page 635.

isolation-clause

Specifies the isolation level to be used for this statement.

WITH

Introduces the isolation level, which may be one of:

- *RR* Repeatable read
- *RS* Read stability
- *CS* Cursor stability
- *UR* Uncommitted read
- *NC* No commit

If *isolation-clause* is not specified the default isolation is used. For more information on the default isolation, see “[isolation-clause](#)” on page 650.

concurrent-access-resolution-clause

Specifies the concurrent access resolution to use for the select statement. For more information, see “[concurrent-access-resolution-clause](#)” on page 651.

DELETE Rules

Triggers: If the identified table or the base table of the identified view has a delete trigger, the trigger is activated. A trigger might cause other statements to be executed or return error conditions based on the deleted values.

Referential Integrity: If the identified table or the base table of the identified table is a parent table, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION, and the DELETE must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted. Any rows that are dependents of the selected rows are also affected:

- The nullable columns of the foreign keys of any rows that are their dependents in a relationship with a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship with a delete rule of CASCADE are also deleted, and the above rules apply, in turn to those rows.
- The columns of the foreign keys of any rows that are their dependents in a relationship with a delete rule of SET DEFAULT are set to the corresponding default value.

The referential constraints (other than a referential constraint with a RESTRICT delete rule), are effectively checked at the end of the statement. In the case of a multiple-row delete, this would occur after all rows were deleted and any associated triggers were activated.

Check Constraints: A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL or SET DEFAULT. If deleting a row in the parent table would cause a column in a dependent table to be set to null or a default value and the null or default value would cause a search condition of a check constraint to evaluate to false, the row is not deleted.

Notes

Delete operation errors: If an error occurs while executing any delete operation, changes from this statement, referential constraints, and any triggered SQL statements are rolled back (unless the isolation level is NC for this statement or any other triggered SQL statements).

Locking: Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful DELETE statement. Until the locks are released by a commit or rollback operation, the effect of the DELETE operation can only be perceived by:

- The application process that performed the deletion
- Another application process using isolation level UR or NC

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the COMMIT, ROLLBACK, and LOCK TABLE statements, and “[Isolation level](#)” on page 23.

If an application process deletes a row on which any of its non-updatable cursors are positioned, those cursors are positioned before the next row of their result table. Let C be a cursor that is positioned before the next row R (as the result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a Searched DELETE). In the presence of INSERT, UPDATE, and DELETE operations that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R' where R' is a new row that is now the next row of the result table.

A maximum of 4000000 rows can be deleted or changed in any single DELETE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger, a CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.

Position of cursor: If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of their result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a Searched DELETE). In the presence of INSERT, UPDATE, and DELETE operations that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.

Number of rows deleted: When a DELETE statement is completed, the number of rows deleted is returned in the ROW_COUNT condition area item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA). The value in the ROW_COUNT item does not include the number of rows that were deleted as a result of a CASCADE delete rule or a trigger.

For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#).

DELETE Performance: An SQL DELETE statement that does not contain a WHERE clause, *offset-clause*, or *fetch-clause* will delete all rows of a table. In this case, the rows may be deleted using either a clear operation (if not running under commitment control) or a change file operation (if running under commitment control). If running under commitment control, the deletes can still be committed or rolled back. This implementation will be much faster than individually deleting each row, but individual journal entries for each row will not be recorded in the journal. This technique will only be used if all the following are true:

- The target table is not a view.
- The target table is not a system-period temporal table.
- A significant number of rows are being deleted.
- The job issuing the DELETE statement does not have an open cursor on the file (not including pseudo-closed SQL cursors).
- No other job has a lock on the table.
- The table does not have an active delete trigger.
- The table is not the parent in a referential constraint with a CASCADE, SET NULL, or SET DEFAULT delete rule.
- The user issuing the DELETE statement has *OBJMGT or *OBJALTER system authority on the table in addition to the DELETE privilege.
- The SQL_FAST_DELETE_ROW_COUNT QAQQINI option allows fast delete.

If this technique is successful, the number of increments (see the SIZE keyword on the CHGPF CL command) is set to zero.

The TRUNCATE statement can be used to delete all rows from a table.

Referential integrity considerations: The DB2_ROW_COUNT_SECONDARY condition information item in the SQL Diagnostics Area (or SQLERRD(5) in the SQLCA) shows the number of rows affected by referential

constraints. It includes rows that were deleted as the result of a CASCADE delete rule and rows in which foreign keys were set to NULL or the default value as the result of a SET NULL or SET DEFAULT delete rule.

For a description of DB2_ROW_COUNT_SECONDARY, see “[GET DIAGNOSTICS](#)” on page 1144. For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),”](#) on page 1431.

Deleting rows in a table for which row access control is enforced: When a DELETE statement is issued for a table for which row access control is enforced, the rules specified in the enabled row permissions determine whether the row can be deleted. Typically those rules are based on the authorization ID of the statement. The following describes how enabled row permissions and column masks are used during DELETE:

- Row permissions are used to identify the set of rows to be deleted.

When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID of the DELETE statement. If the WHERE clause is specified in the DELETE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be deleted. If there is no WHERE clause, all the accessible rows are the rows to be deleted.

Considerations for a system-period temporal table: If the DELETE statement has a search condition that contains a correlated subquery that references the history table (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows that are subsequently processed for the statement.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target of the DELETE statement must not be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

Considerations for a history table: When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. The database manager assigns the value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for an end column in a history table across transactions. The timestamp value might be adjusted to ensure that rows inserted into the history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. Otherwise an error is returned.

For a delete operation, the adjustment only affects the value for the end column in the history table that corresponds to the row-end column in the associated system-period temporal table. Take these adjustments into consideration on subsequent references to the table when there is a search for the transaction start time in the row-begin column and row-end column for the SYSTEM_TIME period of the associated system-period temporal table.

When the history table is defined with ON DELETE ADD EXTRA ROW, the version of the row prior to the delete is added to the history table. Values for the row begin, row end, and any generated expression columns are generated when this row is added. This information represents when the row was deleted.

REXX: Variables cannot be used in the DELETE statement within a REXX procedure. Instead, the DELETE must be the object of a PREPARE and EXECUTE using parameter markers.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.

- The keyword ALL can be used as a synonym for RS.
- The FROM keyword is optional.

Examples

Example 1: Delete department (DEPTNO) 'D11' from the DEPARTMENT table.

```
DELETE FROM DEPARTMENT
WHERE DEPTNO = 'D11'
```

Example 2: Delete all the departments from the DEPARTMENT table (that is, empty the table).

```
DELETE FROM DEPARTMENT
```

Example 3: Use a Java program statement to delete all the subprojects (MAJPROJ is NULL) from the PROJECT table on the connection context 'ctx', for a department (DEPTNO) equal to that in the host variable HOSTDEPT (java.lang.String).

```
#sql [ctx] { DELETE FROM PROJECT
    WHERE DEPTNO = :HOSTDEPT
    AND MAJPROJ IS NULL };
```

Example 4: Code a portion of a Java program that will be used to display retired employees (JOB) and then, if requested to do so, remove certain employees from the EMPLOYEE table on the connection context 'ctx'.

```
#sql iterator empIterator implements sqlj.runtime.ForUpdate
( ... );
empIterator C1;

#sql [ctx] C1 = { SELECT * FROM EMPLOYEE
    WHERE JOB = 'RETIRED' };

#sql { FETCH C1 INTO ...      };
while ( !C1.endFetch() ) {
    System.out.println( ... );
    ...
    if ( condition for deleting row ) {
        #sql [ctx] { DELETE FROM EMPLOYEE
            WHERE CURRENT OF C1 } ;
    }
    #sql { FETCH C1 INTO ...      };
}
C1.close();
```

DESCRIBE

The DESCRIBE statement obtains information about a prepared statement.

For an explanation of prepared statements, see “[PREPARE](#)” on page 1236.

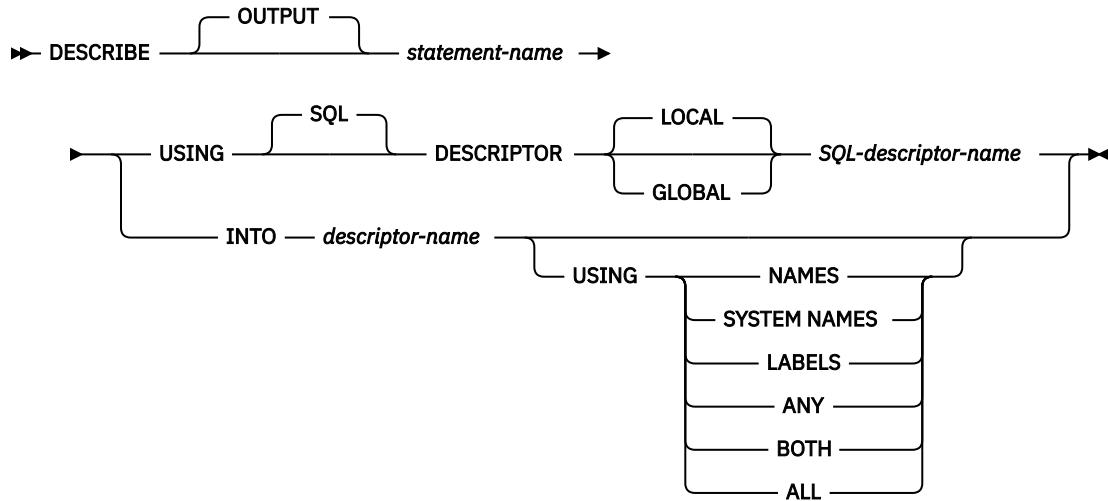

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required. See “[PREPARE](#)” on page 1236 for the authorization required to create a prepared statement.

Syntax

Description

statement-name

Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a prepared statement at the application server.

If the prepared statement is a fullselect or VALUES INTO statement, the information returned describes the columns in its result table. If the prepared statement is a CALL statement, the information returned describes the OUT and INOUT parameters of the procedure.

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO descriptor-name

Identifies an SQL descriptor area (SQLDA), which is described in [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#). Before the DESCRIBE statement is executed, the following variable in the SQLDA must be set.

SQLN

Indicates the number of SQLVAR entries provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE statement is executed. For information about techniques to determine the number of occurrences requires, see “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

The rules for REXX are different. For more information, see the [Embedded SQL Programming](#) topic collection.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

The seventh byte is set based on the result columns described:

- If the SQLDA contains two, three, or four SQLVAR entries for every select list item (or, column of the result table), the seventh byte is set to '2', '3', or '4'. This technique is used in order to accommodate LOB or distinct type result columns, labels, and system names.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all result columns.

The eighth byte is set to the space character.

SQLDABC

Length of the SQLDA in bytes.

SQLD

If the prepared statement is a SELECT, SQLD is set to the number of columns in its result table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, “[Field descriptions in an occurrence of SQLVAR](#)” on page 1443. If the prepared statement is a CALL statement, SQLD is set to the number of OUT and INOUT parameters of the procedure. If the prepared statement is a VALUES INTO, SQLD is set to the number of expressions in the VALUES clause plus the number of extended SQLVAR entries. Otherwise, SQLD is set to 0.

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n , where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the result table (or parameter or expression in the VALUES clause), the second occurrence of SQLVAR contains a description of the second column of the result table (or parameter or expression in the VALUES clause), and so on. For information about the values assigned to SQLVAR occurrences, see “[Field descriptions in an occurrence of SQLVAR](#)” on page 1443.

USING

Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or if the length of a name is greater than 30, SQLNAME is set to a length of 0.

NAMES

Assigns the name of the column (or parameter). This is the default. For the DESCRIBE of a prepared statement where the name is explicitly listed in the select-list, the name specified is returned. The column name returned is case sensitive and without delimiters.

SYSTEM NAMES

Assigns the system column name of the column.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

ANY

Assigns the column label. If the column has no label, the column name is used instead.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $2*n$ or $3*n$ (where n is the number of columns in the table or view). The first n occurrences of SQLVAR contain the column names. Either the second or third n occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

ALL

Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to

accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $3*n$ or $4*n$ (where n is the number of columns in the result table). The first n occurrences of SQLVAR contain the system column names. The second or third n occurrences contain the column labels. The third or fourth n occurrences contain the column names if they are different from the system column name. Otherwise the SQLNAME field is set to a length of zero. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

Notes

PREPARE INTO: Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.

Allocating the SQL descriptor: Before the DESCRIBE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of result columns, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: In C, COBOL, PL/I, and RPG, before the DESCRIBE or PREPARE INTO statement is executed, enough storage must be allocated for some number of SQLVAR occurrences. SQLN must then be set to the number of SQLVAR occurrences that were allocated. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR entries must not be less than the number of columns. Furthermore, if the columns include LOBs or distinct types, the number of occurrences of SQLVAR entries should be two times the number of columns. See “[Determining how many SQLVAR occurrences are needed](#)” on page 1441 for more information. Among the possible ways to allocate the SQLDA are the three described below:

First technique

Allocate an SQLDA with enough occurrences of SQLVAR entries to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal two times the maximum number of columns allowed in a result table. Having done the allocation, the application can use this SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique

Repeat the following three steps for every processed select list:

1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR entries; that is, an SQLDA for which SQLN is zero. The value returned for SQLD is either the required number of occurrences of SQLVAR entries or the number of result columns. Because there were no SQLVAR entries, a warning will be issued.¹⁰³
2. If the seventh byte of SQLDAID field is not a blank, then allocate an SQLDA with (the value in the seventh byte of SQLDAID) * SQLD occurrences and set SQLN in the new SQLDA to (the value in the seventh byte of SQLDAID) * SQLD. Otherwise, allocate an SQLDA with SQLD occurrences and set SQLN in the new SQLDA to the value of SQLD.
3. Execute the DESCRIBE statement again, using this new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

Third technique

Allocate an SQLDA that is large enough to handle most, and perhaps all, select lists but is also reasonably small. If an execution of DESCRIBE fails because the SQLDA is too small, allocate a larger SQLDA and execute DESCRIBE again. For the new SQLDA, use the value of SQLD (or double the value of SQLD) returned from the first execution of DESCRIBE for the number of occurrences of SQLVAR entries.

¹⁰³ If LOBs or UDTs are not in the result set, the warning is only returned if the standards option is specified. For information about the standards option, see “[Standards compliance](#)” on page xix.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

Considerations for implicitly hidden columns: A DESCRIBE OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

Example

In a C program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR entries. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR entries and then execute a DESCRIBE statement using that SQLDA.

```
EXEC SQL BEGIN DECLARE SECTION;
  char stmt1_str [200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
struct sqlda initialsqlda;
struct sqlda *sqldaPtr;

EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

... /* code to prompt user for a query, then to generate      */
     /* a select-statement in the stmt1_str                      */
EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;

... /* code to set SQLN to zero and to allocate the SQLDA   */
EXEC SQL DESCRIBE STMT1_NAME INTO :initialsqlda;

if (initialsqlda.sqld == 0); /* statement is a select-statement */
{
  ... /* Code to allocate correct size SQLDA (sets sqldaPtr) */

  if (strcmp(SQLSTATE,"01005") == 0)
  {
    sqldaPtr->sqln = 2*initialsqlda.sqld;
    SETSQLDOUBLED(sqldaPtr, SQLDOUBLED);
  }
  else
  {
    sqldaPtr->sqln = initialsqlda.sqld;
    SETSQLDOUBLED(sqldaPtr, SQLSINGLED);
  }
  EXEC SQL DESCRIBE STMT1_NAME INTO :sqldaPtr;

  ... /* code to prepare for the use of the SQLDA           */
  EXEC SQL OPEN DYN_CURSOR;

  ... /* loop to fetch rows from result table             */
  EXEC SQL FETCH DYN_CURSOR USING DESCRIPTOR :sqldaPtr;
}

...
...
```

DESCRIBE CURSOR

The DESCRIBE CURSOR statement gets information about a cursor. The information, such as column information, is put into a descriptor.

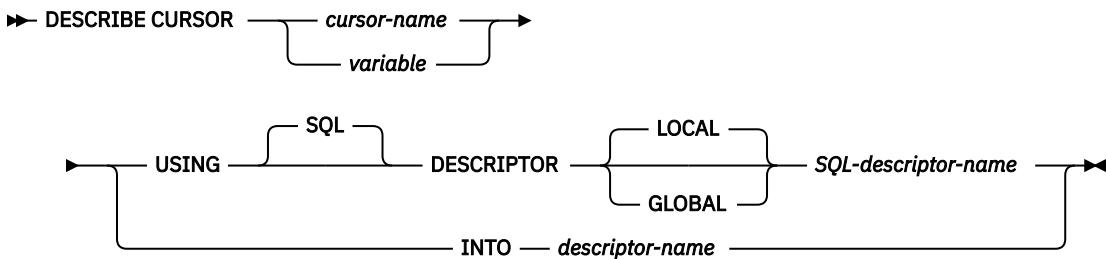

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

Description

cursor-name or variable

Identifies a cursor that has already been open or allocated in the source program.

If a *variable* is specified:

- It must be a character-string variable or Unicode graphic-string. It cannot be a global variable.
- It must not be followed by an indicator variable.
- The cursor name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name of the cursor must be in uppercase unless the cursor name is a delimited name.

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

The information returned in the descriptor area describes the columns in the result set associated with the named cursor. After the DESCRIBE CURSOR is executed, the contents of the descriptor area are the same as after a DESCRIBE of a SELECT with the following addition.

- DB2_CURSOR_HOLD can be returned from the GET DESCRIPTOR statement to indicate whether the cursor was declared WITH HOLD in the procedure.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO descriptor-name

Identifies an SQL descriptor area (SQLDA), which is described in [Appendix D, “SQLDA \(SQL descriptor area\),”](#) on page 1439. Before the DESCRIBE CURSOR statement is executed, the following variable in the SQLDA must be set.

SQLN

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE CURSOR statement is executed. For information about techniques to determine the number of occurrences required, see “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 5 bytes are set to 'SQLRS'. Bytes 6 to 8 are reserved. If the cursor is declared WITH HOLD in the procedure, the high-order bit of the 8th byte is set to 1.

SQLDABC

Length of the SQLDA in bytes.

SQLD

The number of columns in the result table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, “[Field descriptions in an occurrence of SQLVAR](#)” on page 1443.

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n , where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the result table, the second occurrence of SQLVAR contains a description of the second column of the result table, and so on. For information about the values assigned to SQLVAR occurrences, see “[Field descriptions in an occurrence of SQLVAR](#)” on page 1443.

Notes

Allocating the SQL descriptor: Before the DESCRIBE CURSOR statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of columns in the cursor result set, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: Before the DESCRIBE CURSOR statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the columns of the cursor result set, the number of occurrences of SQLVAR must not be less than the number of columns.

For a description of techniques that can be used to allocate the SQLDA, see [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#).

Example

Place information about the result set associated with cursor C1 into an SQL descriptor.

```
EXEC SQL ALLOCATE DESCRIPTOR 'DESCR1';
EXEC SQL DESCRIBE CURSOR C1 USING SQL DESCRIPTOR 'DESCR1';
```

DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the IN and INOUT parameter markers of a prepared statement.

For an explanation of prepared statements, see “[PREPARE](#)” on page 1236.

Invocation

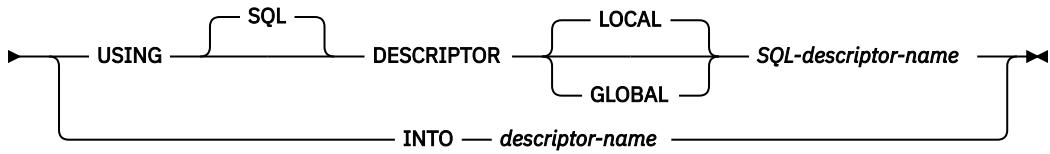

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

Authorization

None required. See “[PREPARE](#)” on page 1236 for the authorization required to create a prepared statement.

Syntax

►► DESCRIBE INPUT — *statement-name* ►►

Description

statement-name

Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a prepared statement at the current server.

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, “[SQLDA \(SQL descriptor area\)](#),” on page 1439. Before the DESCRIBE INPUT statement is executed, the following variable in the SQLDA must be set.

SQLN

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE INPUT statement is executed. For information about techniques to determine the number of occurrences requires, see “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

When the DESCRIBE INPUT statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

The seventh byte is set based on the parameter markers described:

- If the SQLDA contains two SQLVAR entries for every input parameter marker, the seventh byte is set to '2'. This technique is used in order to accommodate LOB input parameters.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all input parameter markers.

The eighth byte is set to the space character.

SQLDABC

Length of the SQLDA in bytes.

SQLD

The number of input parameter markers in the prepared statement.

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n , where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first input parameter marker, the second occurrence of SQLVAR contains a description of the second input parameter marker, and so on. For information about the values assigned to SQLVAR occurrences, see “[Field descriptions in an occurrence of SQLVAR](#)” on page 1443.

Notes

Allocating the SQL descriptor: Before the DESCRIBE INPUT statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. The number of descriptor items allocated must not be less than the number of input parameter markers or an error is returned.

Allocating the SQLDA: Before the DESCRIBE INPUT statement is executed, enough storage must be allocated for some number of SQLVAR occurrences. SQLN must then be set to the number of SQLVAR occurrences that were allocated. To obtain the description of the input parameter markers in the prepared statement, the number of occurrences of SQLVAR must not be less than the number of input parameter markers. Furthermore, if the input parameter markers include LOBs or distinct types, the number of occurrences of SQLVAR should be two times the number of input parameter markers. See “[Determining how many SQLVAR occurrences are needed](#)” on page 1441 for more information.

If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of input parameter markers.

Among the possible ways to allocate the SQLDA are the three described below:

First technique

Allocate an SQLDA with enough occurrences of SQLVAR entries to accommodate any number of input parameter markers that the application will have to process. At the extreme, the number of SQLVARs could equal two times the maximum number of parameter markers allowed in a prepared statement. Having done the allocation, the application can use this SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular prepared statement.

Second technique

Repeat the following three steps for every processed prepared statement:

1. Execute a DESCRIBE INPUT statement with an SQLDA that has no occurrences of SQLVAR entries, that is, an SQLDA for which SQLN is zero. The value returned for SQLD is the number of input parameter markers in the prepared statement. This value is either the required number of occurrences of SQLVAR entries or half the required number. Because there were no SQLVAR entries, a warning will be issued.¹⁰⁴
2. If the SQLSTATE accompanying that warning is equal to 01005, allocate an SQLDA with $2 * \text{SQLD}$ occurrences and set SQLN in the new SQLDA to $2 * \text{SQLD}$. Otherwise, allocate an SQLDA with SQLD occurrences and set SQLN in the new SQLDA to the value of SQLD.
3. Execute the DESCRIBE INPUT statement again, using this new SQLDA.

¹⁰⁴ If LOBs or UDTs are not in the result set, the warning is only returned if the standards option is specified. For information about the standards option, see “[Standards compliance](#)” on page xix.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE INPUT statements.

Third technique

Allocate an SQLDA that is large enough to handle most, and perhaps all, parameter markers in prepared statements but is also reasonably small. If an execution of DESCRIBE INPUT fails because the SQLDA is too small, allocate a larger SQLDA and execute DESCRIBE INPUT again. For the new SQLDA, use the value of SQLD (or double the value of SQLD) returned from the first execution of DESCRIBE INPUT for the number of occurrences of SQLVAR entries.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

Examples

Example 1: In a C program, execute a DESCRIBE INPUT statement with an SQLDA that has enough to describe any number of input parameter markers a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

```
EXEC SQL BEGIN DECLARE SECTION;
  char stmt1_str [200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
struct sqlda initialsqlda;
struct sqlda *sqldaPtr;

... /* stmt1_str contains INSERT statement with VALUES      */
     /* clause                                         */
EXEC SQL PREPARE STMT1_NAME   FROM :stmt1_str;

... /* code to set SQLN to five and to allocate the SQLDA */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;
...
...
```

Example 2: Allocate a descriptor called 'NEWDA' large enough to hold 20 item descriptor areas and use it on DESCRIBE INPUT.

```
EXEC SQL ALLOCATE DESCRIPTOR 'NEWDA'
  WITH MAX 20;

EXEC SQL DESCRIBE INPUT STMT1
  USING SQL DESCRIPTOR 'NEWDA';
```

DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a procedure. The information, such as the number of result sets, is put into a descriptor.

Invocation

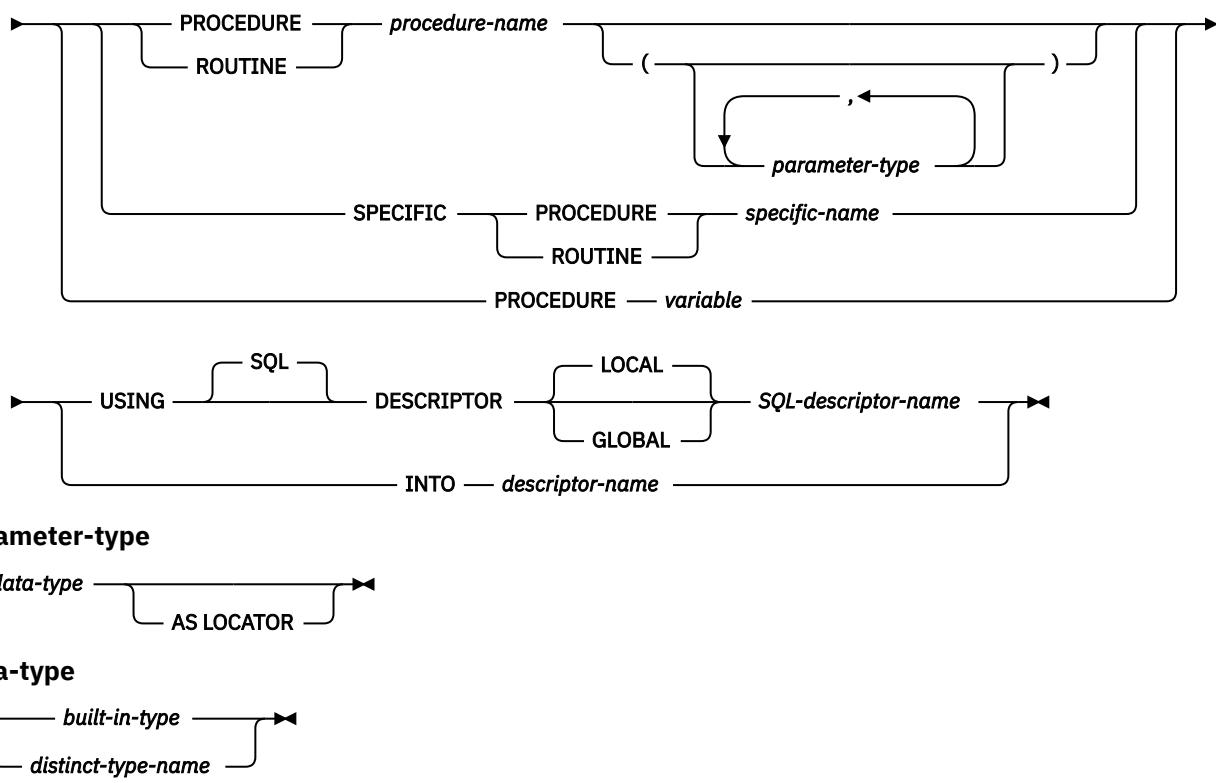

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

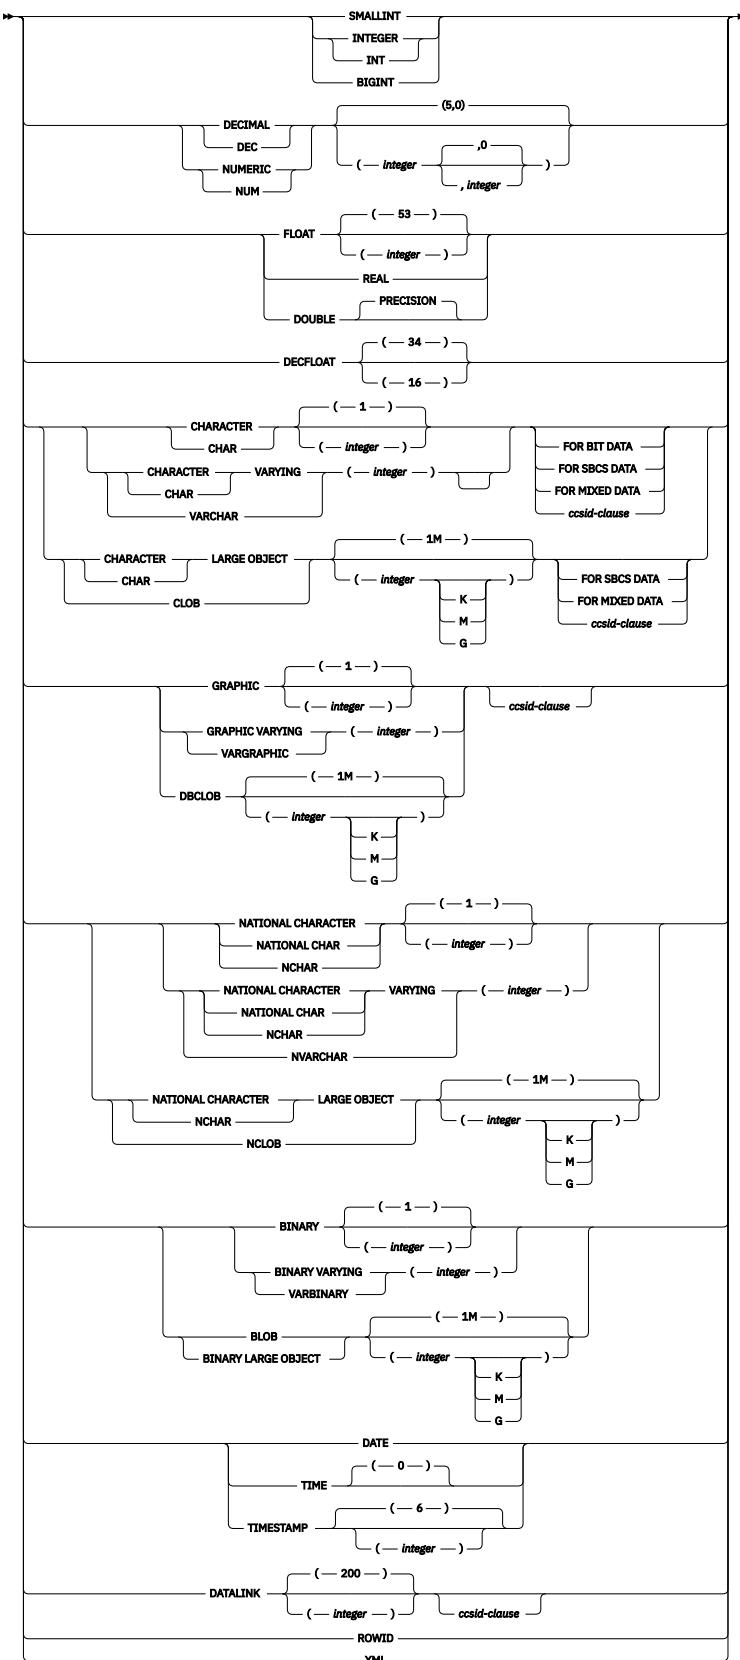

Authorization

None required.

Syntax

►► DESCRIBE ►►

ccsid-clause

►► CCSID — *integer* ►►

Description

procedure-name or specific-name or variable

Identifies the procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a procedure that the requester has already invoked using the SQL CALL statement.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to be described. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type, ...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type, ...)* must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be labeled on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name ()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a

LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

variable

Specifies a variable that contains a procedure or specific name. If *variable* is specified:

- It must be a character-string variable or Unicode graphic-string variable. It cannot be a global variable.
- It must not be followed by an indicator variable.
- The name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name must be in uppercase unless it is a delimited name.

If only one procedure with this name has been invoked using the CALL statement, the variable is used as a procedure name. If multiple procedures with this name have been invoked, the variable is used as a specific name.

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

After the DESCRIBE PROCEDURE is executed, the following values can be retrieved with the GET DESCRIPTOR statement:

- DB2_RESULT_SETS_COUNT contains the total number of result sets. A value of 0 indicates there are no result sets.

There is one descriptor area item for each result set:

- DB2_RESULT_SET_LOCATOR contains the result set locator value associated with the result set.
- DB2_CURSOR_NAME contains the name of the cursor used by the procedure to return the result set.
- DB2_RESULT_SET_ROWS contains the estimated number of rows in the result set. This is set to -1 if the number is unknown.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, “[SQLDA \(SQL descriptor area\)](#),” on page 1439. Before the DESCRIBE PROCEDURE statement is executed, the following variable in the SQLDA must be set.

SQLN

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE PROCEDURE statement is executed.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 5 bytes are set to 'SQLPR'. Bytes 6 to 8 are reserved.

SQLDABC

Length of the SQLDA in bytes.

SQLD

The total number of result sets. A value of 0 indicates there are no result sets.

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n , where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first result set, the second occurrence of SQLVAR contains a description of the second result set, and so on. For each SQLVAR entry:

- The SQLDATA field is set to the result set locator value associated with the result set.
- The SQLIND field is set to the estimated number of rows in the result set. This is set to -1 if the number is unknown.
- The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. The cursor name is truncated to 30 characters if it is longer than 30 characters.

Notes

DESCRIBE PROCEDURE does not return information about the parameters expected by the procedure.

The CALL to the procedure must precede the DESCRIBE PROCEDURE statement.

Allocating the SQL descriptor: Before the DESCRIBE PROCEDURE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of result sets for the procedure, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: Before the DESCRIBE PROCEDURE statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the result sets for the procedure, the number of occurrences of SQLVAR must not be less than the number result sets.

If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of result sets.

Assignment of locator values: If a SET RESULT SETS statement was executed in the procedure, the SET RESULT SETS statement identifies the result sets. The locator values are assigned to the items in the descriptor area or the SQLVAR entries in the SQLDA in the order specified on the SET RESULT SETS statement. If a SET RESULT SETS statement was not executed in the procedure, locator values are assigned to the items in the descriptor area or to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, and C, closes cursor B, and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

Example

Place information about the result sets returned by procedure P1 into an SQL descriptor:

```

EXEC SQL CALL P1;
EXEC SQL ALLOCATE DESCRIPTOR 'DESC1';
EXEC SQL DESCRIBE PROCEDURE P1 USING SQL DESCRIPTOR 'DESC1';

```

DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a table or view.

Invocation

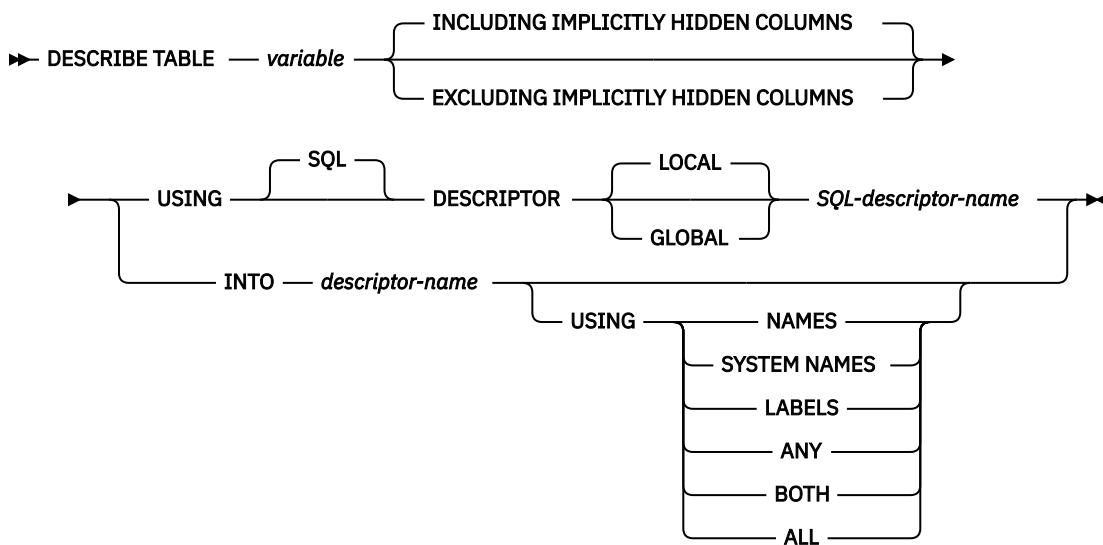

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table or view identified in the statement:
 - The system authority of *OBJOPR on the table or view
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

Syntax

Description

variable

Identifies the table or view to describe. When the DESCRIBE TABLE statement is executed:

- The name must identify a table or view that exists at the application server.
- The *variable* must be a character-string or Unicode graphic-string variable and must not include an indicator variable. It cannot be a global variable.
- The table name that is contained within the *variable* must be left-justified and must be padded on the right with blanks if its length is less than that of the *variable*.
- The name of the table must be in uppercase unless it is a delimited name.

INCLUDING IMPLICITLY HIDDEN COLUMNS or EXCLUDING IMPLICITLY HIDDEN COLUMNS

Specifies whether information should be returned for implicitly hidden column in a table.

INCLUDING IMPLICITLY HIDDEN COLUMNS

Specifies that information is returned for columns defined as implicitly hidden. This is the default.

EXCLUDING IMPLICITLY HIDDEN COLUMNS

Specifies that information is not returned for columns defined as implicitly hidden.

When the DESCRIBE TABLE statement is executed, the database manager assigns values to the variables of the SQL descriptor or SQLDA as follows:

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#). Before the DESCRIBE TABLE statement is executed, the following variable in the SQLDA must be set.

SQLN

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE TABLE statement is executed. For information about techniques to determine the number of occurrences requires, see [“Determining how many SQLVAR occurrences are needed” on page 1441](#).

The rules for REXX are different. For more information, see the [Embedded SQL Programming](#) topic collection.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

The seventh byte is set based on the column described:

- If the SQLDA contains two, three, or four SQLVAR entries for every column of the table, the seventh byte is set to '2', '3', or '4'. This technique is used in order to accommodate LOB or distinct type result columns, labels, and system names.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all columns.

The eighth byte is set to the space character.

SQLDABC

Length of the SQLDA in bytes.

SQLD

The number of columns in the table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, [“Field descriptions in an occurrence of SQLVAR” on page 1443](#).

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n , where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the table, the second occurrence of SQLVAR contains a description of the second column of the table, and so on. For information about the values assigned to SQLVAR occurrences, see “[Field descriptions in an occurrence of SQLVAR](#)” on page [1443](#).

USING

Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or if the length of a name is greater than 30, SQLNAME is set to a length of 0.

NAMES

Assigns the name of the column. The column name returned is case sensitive and without delimiters. This is the default.

SYSTEM NAMES

Assigns the system column name of the column.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

ANY

Assigns the column label. If the column has no label, the column name is used instead.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $2*n$ or $3*n$ (where n is the number of columns in the table or view). The first n occurrences of SQLVAR contain the column names if they are different from the system column name. Either the second or third n occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

ALL

Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $3*n$ or $4*n$ (where n is the number of columns in the table). The first n occurrences of SQLVAR contain the system column names. The second or third n occurrences contain the column labels. The third or fourth n occurrences contain the column names. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

Notes

Allocating the SQL descriptor: Before the DESCRIBE TABLE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of columns in the table or view, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: Before the DESCRIBE TABLE statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the columns of the table or view, the number of occurrences of SQLVAR must not be less than the number of columns. Furthermore, if USING BOTH or USING ALL is specified, or if the columns include

LOBs or distinct types, the number of occurrences of SQLVAR should be two, three, or four times the number of columns. See “[Determining how many SQLVAR occurrences are needed](#)” on page 1441 for more information.

If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of columns.

For a description of techniques that can be used to allocate the SQLDA, see [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#).

Example

In a C program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA.

```
EXEC SQL BEGIN DECLARE SECTION;
  char table_name[201];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

.../*code to prompt user for a table or view */
.../*code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE TABLE :table_name INTO :sqlda;

... /* code to check that SQLD is greater than zero, to set */
    /* SQLN to SQLD, then to re-allocate the SQLDA           */
EXEC SQL DESCRIBE TABLE :table_name INTO :sqlda;

.
.
.
```

DISCONNECT

The DISCONNECT statement ends one or more connections for unprotected conversations.

Invocation

This statement can only be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

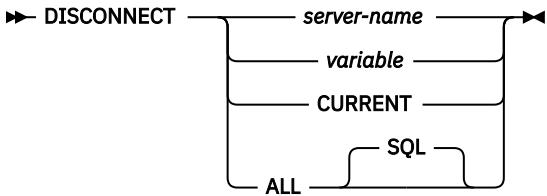

DISCONNECT is not allowed in a trigger or function.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

server-name or variable

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the DISCONNECT statement is executed, the specified server name or server name contained in the variable must identify an existing dormant or current connection of the activation group. The identified connection cannot use a protected conversation.

CURRENT

Identifies the current connection of the activation group. The activation group must be in the connected state. The current connection must not use a protected conversation.

ALL or ALL SQL

Identifies all existing connections of the activation group (local as well as remote connections). An error or warning does not occur if no connections exist when the statement is executed. None of the connections can use protected conversations.

Notes

DISCONNECT and CONNECT (Type 1): Using CONNECT (Type 1) semantics does not prevent using DISCONNECT.

Connection restrictions: An identified connection must not be a connection that was used to execute SQL statements during the current unit of work and must not be a connection for a protected conversation. To end connections on protected conversations, use the RELEASE statement. Local connections are never considered to be protected conversations.

The DISCONNECT statement should be executed immediately after a commit operation. If DISCONNECT is used to end the current connection, the next executed SQL statement must be CONNECT or SET CONNECTION.

ROLLBACK does not reconnect a connection that has been ended by DISCONNECT.

Successful disconnect: If the DISCONNECT statement is successful, each identified connection is ended. If the current connection is destroyed, the activation group is placed in the unconnected state.

DISCONNECT closes cursors, releases resources, and prevents further use of the connection.

DISCONNECT ALL ends the connection to the local application server. A connection is ended even though it has an open cursor defined with the WITH HOLD clause.

Unsuccessful disconnect: If the DISCONNECT statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Resource considerations for remote connections: Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be ended as soon as possible and a remote connection that is going to be reused should not be destroyed.

Examples

Example 1: The connection to TOROLAB1 is no longer needed. The following statement is executed after a commit operation.

```
EXEC SQL DISCONNECT TOROLAB1;
```

Example 2: The current connection is no longer needed. The following statement is executed after a commit operation.

```
EXEC SQL DISCONNECT CURRENT;
```

Example 3: The existing connections are no longer needed. The following statement is executed after a commit operation.

```
EXEC SQL DISCONNECT ALL;
```

DROP

The DROP statement drops an object. Objects that are directly or indirectly dependent on that object may also be dropped.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

To drop a table, view, index, alias, or package, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR and *OBJEXIST on the object to be dropped
 - If the object is a table or view, the system authorities of *OBJOPR and *OBJEXIST on any views, indexes, and logical files that are dependent on that table or view
 - If the object is a system-period temporal table, the system authorities of *OBJOPR and *OBJEXIST on the associated history table
 - The USAGE privilege on the schema that contains the object to be dropped
- Database administrator authority

To drop a schema, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJEXIST, *OBJOPR, *EXECUTE, and *READ on the library to be dropped.
 - The system authorities of *OBJOPR and *OBJEXIST on all objects in the schema and *OBJOPR and *OBJEXIST on any views, indexes and logical files that are dependent on tables and views in the schema.

- Any additional authorities required to delete other object types that exist in the schema. For example, *OBJMGT to the data dictionary if the schema contains a data dictionary, and some system data authority to the journal receiver. For more information, see [Security Reference](#).
- Database administrator authority

To drop a user-defined type, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR and *OBJEXIST on the type to be dropped
 - The USAGE privilege on the schema that contains the type to be dropped
 - The DELETE privilege on the SYSTYPES, SYSPARMS, and SYSROUTINES catalog tables, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

To drop a global variable, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authority of *OBJEXIST on the *SRVPGM object for the global variable to be dropped
 - The USAGE privilege on the schema that contains the global variable to be dropped
 - The DELETE privilege on the SYSVARIABLES catalog table, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

To drop an XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR and *OBJEXIST on the *SQLXSR object for the XSR object to be dropped
 - The USAGE privilege on the schema that contains the XSR object to be dropped
 - The DELETE privilege on the XSROBJECTS, XSROBJECTCOMPONENTS, and XSRANNOTATIONINFO catalog tables, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

To drop a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - For SQL functions, the system authority *OBJEXIST on the service program object associated with the function, and
 - The DELETE privilege on the SYSFUNCS, SYSPARMS, and SYSROUTINEDEP catalog tables, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

To drop a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - For SQL procedures, the system authority *OBJEXIST on the program object associated with the procedure, and
 - The DELETE privilege on the SYSPROCS, SYSPARMS, and SYSROUTINEDEP catalog tables, and

- The USAGE privilege on schema QSYS2
- Database administrator authority

To drop a sequence, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authorities *OBJOPR and *OBJEXIST on the data area associated with the sequence, and
 - The USAGE privilege on the schema that contains the sequence to be dropped
 - The DELETE privilege on the SYSSEQOBJECTS catalog table, and
 - The USAGE privilege on schema QSYS2, and
 - *USE to the Delete Data Area (DLTDTAARA) command
- Database administrator authority

To drop a trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following privileges:
 - The system authority *USE to the Remove Physical File Trigger (RMVPFTRG) command, and
 - For the subject table or view of the trigger:
 - The ALTER privilege to the subject table or view, and
 - The USAGE privilege on the schema containing the subject table or view,
 - If the trigger being dropped is an SQL trigger:
 - The system authority *OBJEXIST on the trigger program object, and
 - The USAGE privilege on the schema containing the trigger.
- Database administrator authority

To drop a mask or permission:

- The authorization ID of the statement must have security administrator authority. See “[Administrative authority](#)” on page 15.

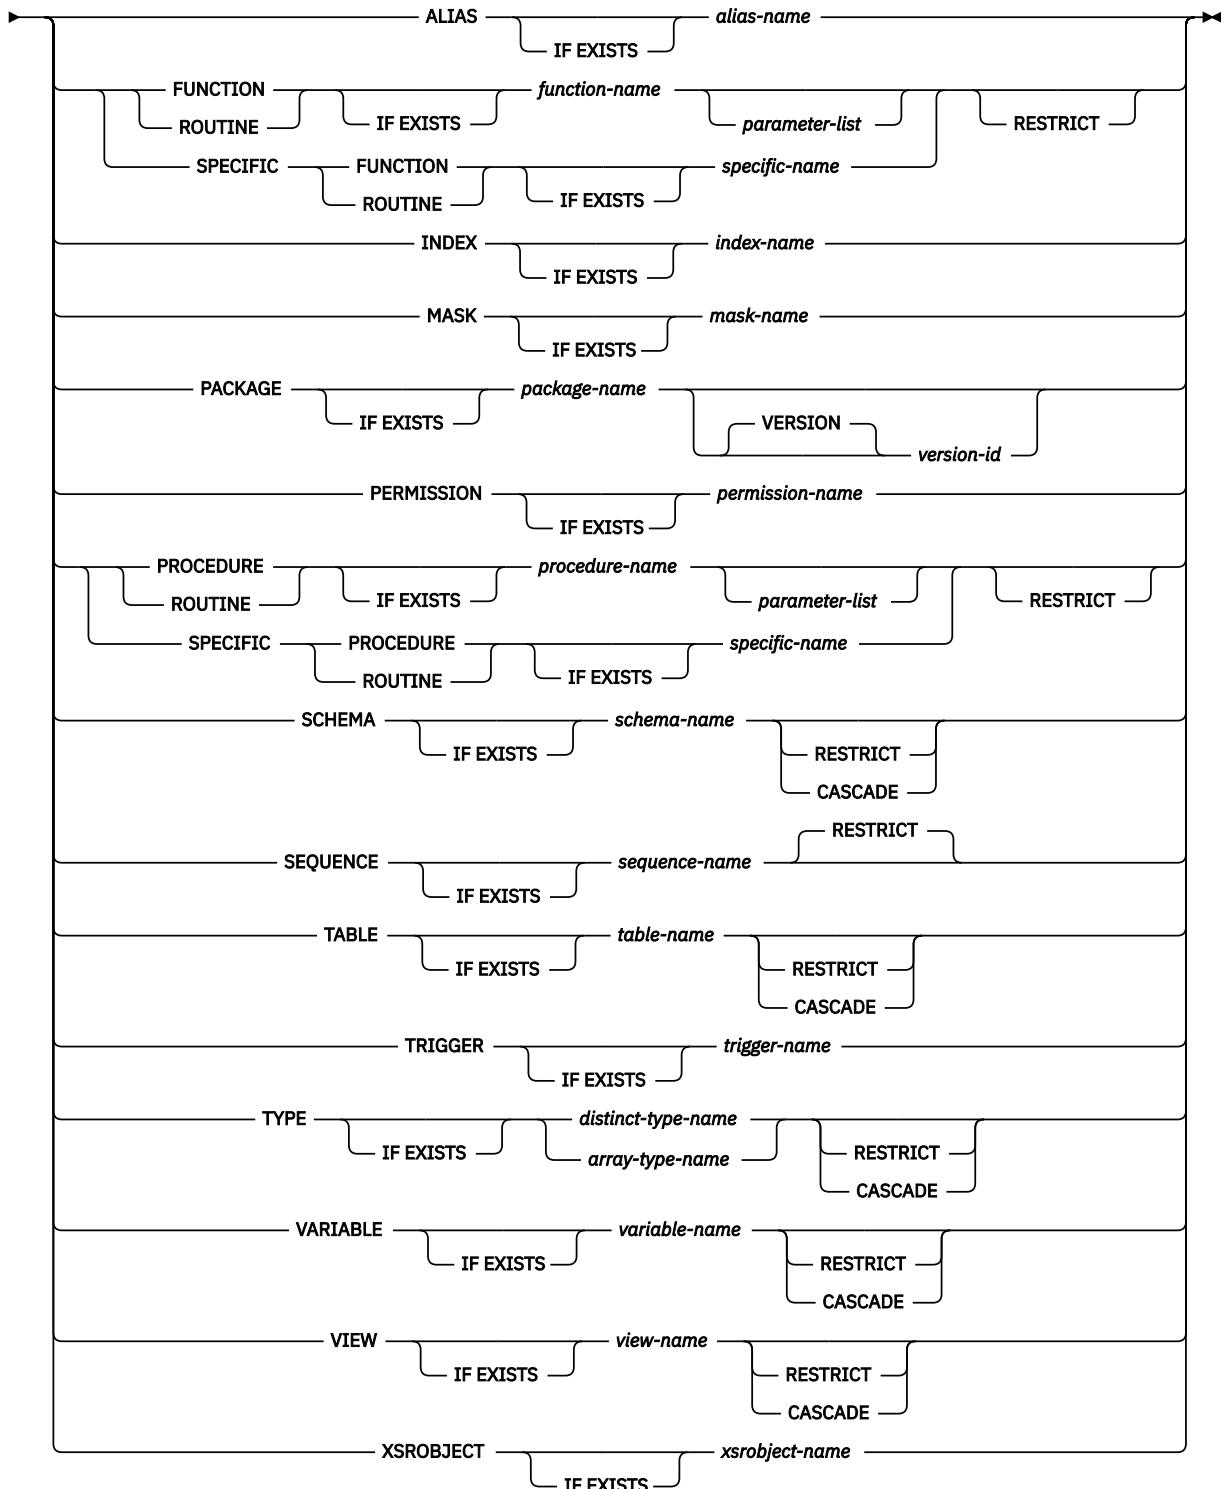

To drop an object used by a mask or permission:

- The authorization ID of the statement must have security administrator authority. See “[Administrative authority](#)” on page 15.

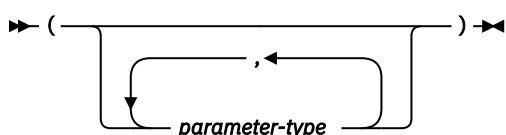

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

►► DROP ►►

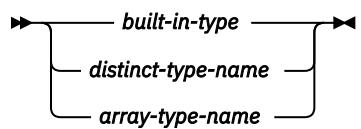

parameter-list

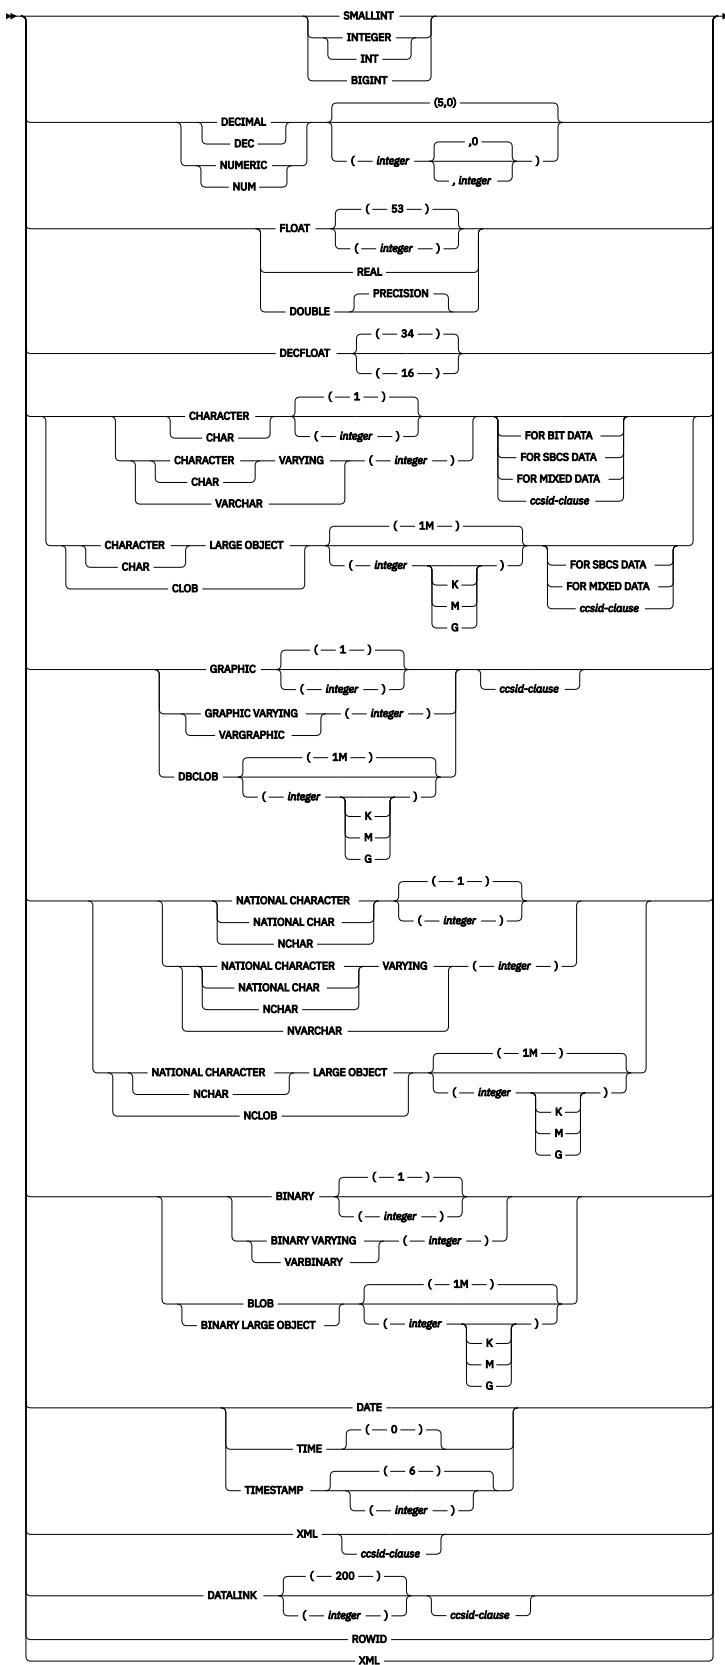

parameter-type

data-type

built-in-type

ccsid-clause

►► CCSID — *integer* ►►

Description

IF EXISTS

Specifies that no error is issued if the specified object does not exist. Unless other conditions or dependencies prevent the drop operation, a successful SQLSTATE is returned even if no object is dropped.

ALIAS *alias-name*

Identifies the alias that is to be dropped. The *alias-name* must identify an alias that exists at the current server.

The specified alias is deleted from the schema. Dropping an alias has no effect on any constraint, view, or materialized query that was defined using the alias. An alias can be dropped whether it is referenced in a function, package, procedure, program, trigger, or variable.

FUNCTION or SPECIFIC FUNCTION

Identifies the function that is to be dropped. The function must exist at the current server and it must be a function that was defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name.

Functions implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

The function cannot be dropped if another function is dependent on it. A function is dependent on another function if it was identified in the SOURCE clause of the CREATE FUNCTION statement. A function can be dropped whether it is referenced in a function, package, procedure, program, trigger, variable, or view unless RESTRICT is specified. A function cannot be dropped if it is referenced in a mask or permission even if RESTRICT is not specified.

The specified function is dropped from the schema. All privileges on the user-defined function are also dropped. If this is an SQL function or sourced function, the service program (*SRVPGM) associated with the function is also dropped. If this is an external function, the information that was saved in the program or service program specified on the CREATE FUNCTION statement is removed from the object.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name* (*parameter-type*, ...)

Identifies the function by its function signature, which uniquely identifies the function. The *function-name* (*parameter-type*, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped.

Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name* () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(*parameter-type*, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot

be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

RESTRICT

Specifies that the function cannot be dropped if it is referenced in an SQL function, SQL procedure, table, mask, permission, SQL trigger, variable, or view.

RESTRICT not specified

If the function is referenced in a mask or permission, the drop will fail unless the authorization ID of the statement has security administrator authority.

INDEX *index-name*

Identifies the index that is to be dropped. The *index-name* must identify an index that exists at the current server.

The specified index is dropped from the schema. An index can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

MASK *mask-name*

Identifies the mask that is to be dropped. The *mask-name* must identify a mask that exists at the current server.

The specified mask is dropped from the schema. A mask can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PACKAGE *package-name*

Identifies the package that is to be dropped. The *package-name* must identify a package that exists at the current server.

The specified package is dropped from the schema. All privileges on the package are also dropped.

A package can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

VERSION *version-id*

version-id is the version identifier that was assigned to the package when it was created. If *version-id* is not specified, a null string is used as the version identifier.

PERMISSION *permission-name*

Identifies the permission that is to be dropped. The *permission-name* must identify a permission that exists at the current server.

The specified permission is dropped from the schema. A permission can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure that is to be dropped. The *procedure-name* must identify a procedure that exists at the current server.

The specified procedure is dropped from the schema. All privileges on the procedure are also dropped. If this is an SQL procedure, the program (*PGM) or service program (*SRVPGM) associated with the procedure is also dropped. If this is an external procedure, the information that was saved in the program specified on the CREATE PROCEDURE statement is removed from the object.

A procedure can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure.

The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name* (*parameter-type*, ...)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure.

The *procedure-name* (*parameter-type*, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be dropped. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name* () is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(*parameter-type*, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

RESTRICT

Specifies that the procedure cannot be dropped if it is referenced in an SQL function, SQL procedure, or SQL trigger.

SCHEMA *schema-name*

Identifies the schema that is to be dropped. The *schema-name* must identify a schema that exists at the current server.

The specified schema is dropped. Each object in the schema is dropped as if the appropriate DROP statement was executed with the specified drop option (CASCADE, RESTRICT, or neither). See the DROP description of these object types for information about the handling of objects dependent on these objects.

DROP SCHEMA is only valid when the commit level is *NONE.

Neither CASCADE nor RESTRICT

Specifies that the schema will be dropped even if it is referenced in a function, package, procedure, program, table, mask, permission, trigger, or variable in another schema.

CASCADE

Specifies that any objects in the schema and any triggers that reference the schema will be dropped. Any masks and permissions in a different schema that reference the schema are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the schema cannot be dropped if it is referenced in an SQL trigger, mask, or permission in another schema or if the schema contains any SQL objects other than catalog views, the journal, and journal receiver.

SEQUENCE *sequence-name*

Identifies the sequence that is to be dropped. The *sequence-name* must identify a sequence that exists at the current server.

RESTRICT

Specifies that the sequence cannot be dropped if it is referenced in an SQL trigger, function, procedure, or variable.

TABLE *table-name*

Identifies the table that is to be dropped. The *table-name* must identify a base table that exists at the current server, but must not identify a catalog table or a history table for a system-period temporal table.

The specified table is dropped from the schema. All privileges, constraints, indexes, masks, permissions, and triggers on the table are also dropped.

Any aliases that reference the specified table are not dropped.

Neither CASCADE nor RESTRICT

Specifies that the table will be dropped even if it is referenced in a constraint, index, trigger, mask, permission, view, or materialized query table. All indexes, views, and materialized query tables that reference the table are dropped even if the authorization ID of the statement does not explicitly have privileges to those objects. If the table is a system-period temporal table, the history table is also dropped. If the table is referenced in a mask or permission, the drop will fail unless the authorization ID of the statement has security administrator authority.

CASCADE

Specifies that the table will be dropped even if it is referenced in a constraint, index, trigger, variable, mask, permission, view, XSR object, or materialized query table. All constraints, indexes, triggers, variables, views, XSR objects and materialized query tables that reference the table are dropped even if the authorization ID of the statement does not explicitly have privileges to those objects. If the table is a system-period temporal table, the history table is also dropped. All masks

and permissions that reference the table are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the table cannot be dropped if it is referenced in a constraint, index, mask, permission, trigger, variable, view, XSR object, or materialized query table, or if it is a system-period temporal table.

TRIGGER *trigger-name*

Identifies the trigger that is to be dropped. The *trigger-name* must identify a trigger that exists at the current server.

The specified trigger is dropped from the schema. If the trigger is an SQL trigger, the program object associated with the trigger is also deleted from the schema.

If *trigger-name* specifies an INSTEAD OF trigger on a view, another trigger may depend on that trigger through an update against the view.

TYPE *distinct-type-name* or *array-type-name*

Identifies the type that is to be dropped. The *distinct-type-name* or *array-type-name* must identify a distinct type or array type that exists at the current server. The specified type is deleted from the schema.

Neither CASCADE nor RESTRICT

Specifies that the type cannot be dropped if any constraints, indexes, masks, permissions, sequences, tables, variables, and views reference the type.

For every procedure or function R that has parameters or a return value of the type being dropped, the following DROP statement is effectively executed:

```
DROP ROUTINE R
```

For every trigger T that references the type being dropped, the following DROP statement is effectively executed:

```
DROP TRIGGER T
```

It is possible that this statement would cascade to drop dependent functions or procedures. If all of these functions or procedures are in the list to be dropped because of a dependency on the type, the drop of the type will succeed.

CASCADE

Specifies that the type will be dropped even if it is referenced in a constraint, function, index, procedure, sequence, table, trigger, variable, or view. All constraints, functions, indexes, procedures, sequences, tables, triggers, variables, and views that reference the type are dropped. The cascade processing is limited to cases where the type is used to define the routine parameter type, sequence type, variable type and column type. All masks and permissions that reference the type are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the type cannot be dropped if it is referenced in a constraint, function (other than a function that was created when the type was created), index, procedure, sequence, table, mask, permission, trigger, variable, or view. The restrict checking is limited to cases where the type is used to define the routine parameter type, sequence type, variable type and column type.

VARIABLE *variable-name*

Identifies the variable that is to be dropped. The *variable-name* must identify a variable that exists at the current server. The specified variable is dropped from the schema.

Neither CASCADE nor RESTRICT

Specifies that the variable will be dropped even if it is referenced in a trigger, procedure, function, mask, permission, view, or another variable. All tables and views that reference the variable are dropped. If the variable is referenced in a mask or permissions, the drop will fail unless the authorization ID of the statement has security administrator authority.

CASCADE

Specifies that the variable will be dropped even if it is referenced in a table, trigger, procedure, function, view, or another variable. All tables, triggers, procedures, functions, views, and variables that reference the variable are dropped. All masks and permissions that reference the variable are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the variable cannot be dropped if it is referenced in a table, trigger, procedure, function, mask, permission, view, or another variable.

VIEW *view-name*

Identifies the view that is to be dropped. The *view-name* must identify a view that exists at the current server, but must not identify a catalog view.

The specified view is dropped from the schema. When a view is dropped, all privileges and triggers on that view are dropped.

Neither CASCADE nor RESTRICT

Specifies that the view will be dropped even if it is referenced in a trigger, materialized query table, mask, permission, or another view. All views and materialized query tables that reference the view are dropped. If the view is referenced in a mask or permissions, the drop will fail unless the authorization ID of the statement has security administrator authority.

CASCADE

Specifies that the view will be dropped even if it is referenced in a trigger, variable, materialized query table, or another view. All triggers, variables, materialized query tables, and views that reference the view are dropped. All masks and permissions that reference the view are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the view cannot be dropped if it is referenced in a trigger, variable, mask, permission, materialized query table, or another view.

XSROBJECT *xsrobject-name*

Identifies the XSR object that is to be dropped. The *xsrobject-name* must identify an XSR object that exists at the current server. The specified XSR object is dropped.

Notes

Drop effects: Whenever an object is dropped, its description is dropped from the catalog. If the object is referenced in a function, package, procedure, program, trigger, or variable; any access plans that reference the object are implicitly prepared again when the access plan is next used. If the object does not exist at that time, an error is returned.

Dependencies: Whenever an object is directly or indirectly dropped, other objects that depend on the dropped object might also be dropped. The following semantics determine what happens to a dependent object when the object that it depends on (the underlying object) is dropped:

Three different types of dependencies are shown:

D

Dependent object is dropped.

A

Automatic revalidation is required. The database manager will attempt to revalidate the object when it is referenced.

R

DROP statement fails.

Table 99. Effect of dropping objects that have dependencies

Drop Statement	ALIAS	CONSTRAINT	FUNCTION	INDEX	MASK	PERMISSION	PROCEDURE	SCHEMA	SEQUENCE	TABLE	TRIGGER	TYPE	VARIABLE	VIEW

DROP VIEW RESTRICT	A		R	R	A			R	R		R	R	R	
DROP XSROBJ	A		A	A	A			A		A	A	A	A	

Notes:

1. If other user-defined functions are sourced on the function being dropped, the function cannot be dropped.
2. DROP SCHEMA will drop all objects in the schema. Any objects in other schemas that reference the schema will not be changed and will require automatic revalidation.
3. DROP SCHEMA CASCADE will drop all objects in the schema. Triggers in other schemas that reference the schema will be dropped. Other objects in other schemas that reference the schema will not be changed and will require automatic revalidation.
4. DROP SCHEMA RESTRICT will fail if any object other than SQL catalog views, journals, and journal receivers exist in the schema. Objects other than triggers in other schemas that reference the schema will not be changed and will require automatic revalidation.
5. Any function or procedure that has a parameter or returns value defined as the type will be dropped.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword SYNONYM can be used as a synonym for ALIAS.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.
- The keyword PROGRAM can be used as a synonym for PACKAGE.

- The keyword COLLECTION can be used as a synonym for SCHEMA.

For compatibility with other database products, the IF EXISTS clause can be specified following *table-name* for DROP TABLE.

Examples

Example 1: Drop your table named MY_IN_TRAY. Do not allow the drop if any views or indexes are created over this table.

```
DROP TABLE MY_IN_TRAY RESTRICT
```

Example 2: Drop your view named MA_PROJ.

```
DROP VIEW MA_PROJ
```

Example 3: Drop the package named PERS.PACKA.

```
DROP PACKAGE PERS.PACKA
```

Example 4: Drop the distinct type DOCUMENT, if it is not currently in use:

```
DROP DISTINCT TYPE DOCUMENT RESTRICT
```

Example 5: Assume that you are SMITH and that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Drop ATOMIC_WEIGHT.

```
DROP FUNCTION CHEM.ATOMIC_WEIGHT RESTRICT
```

Example 6: Drop the function named CENTER, using the function signature to identify the function instance to be dropped.

```
DROP FUNCTION CENTER (INTEGER, FLOAT) RESTRICT
```

Example 7: Drop CENTER, using the specific name to identify the function instance to be dropped.

```
DROP SPECIFIC FUNCTION JOHNSON.FOCUS97
```

Example 8: Assume that procedure OSMOSIS is in schema BIOLOGY. Drop OSMOSIS.

```
DROP PROCEDURE BIOLOGY.OSMOSIS
```

Example 9: Assume that trigger BONUS exists in the default schema. Drop BONUS.

```
DROP TRIGGER BONUS
```

END DECLARE SECTION

The END DECLARE SECTION statement marks the end of an SQL declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in RPG, Java, or REXX.

Authorization

None required.

Syntax

► END DECLARE SECTION ►

Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement. For more information about the BEGIN DECLARE SECTION statement, see “[BEGIN DECLARE SECTION](#)” on page 770.

The BEGIN DECLARE SECTION and the END DECLARE SECTION statements must be paired and cannot be nested.

Examples

See “[BEGIN DECLARE SECTION](#)” on page 770 for examples using the END DECLARE SECTION statement.

EXECUTE

The EXECUTE statement executes a prepared SQL statement.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

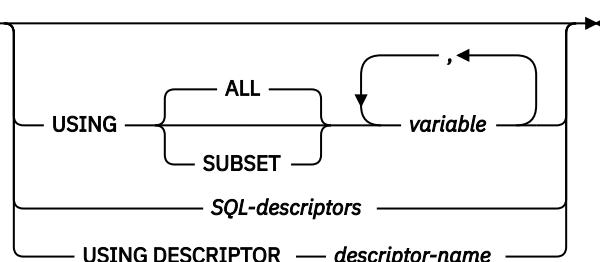

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

The authorization rules are those defined for the SQL statement specified by EXECUTE. For example, see the description of INSERT for the authorization rules that apply when an INSERT statement is executed using EXECUTE.

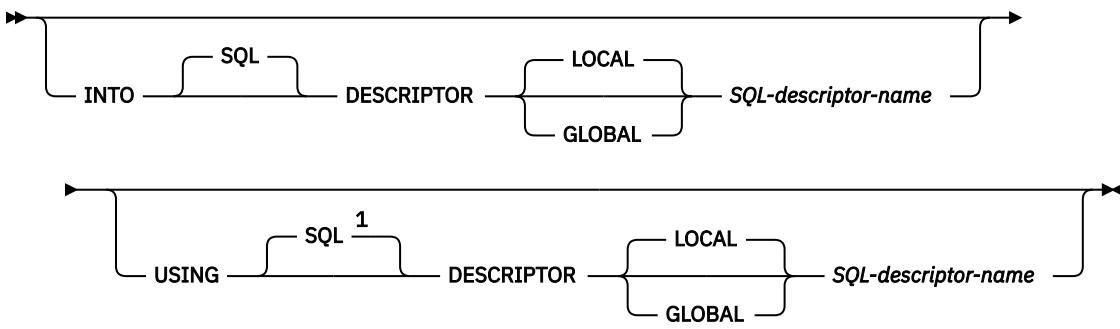

The authorization ID of the statement is the run-time authorization ID unless DYNUSRPRF(*OWNER) was specified on the CRTSQLxxx command when the program was created. For more information, see “[Authorization IDs and authorization names](#)” on page 58.

Syntax

► EXECUTE — *statement-name*

SQL-descriptors

Notes:

¹ If an SQL descriptor is specified in the USING clause and the INTO clause is not specified, USING DESCRIPTOR is not allowed and USING SQL DESCRIPTOR must be specified.

Description

statement-name

Identifies the prepared statement to be executed. When the EXECUTE statement is executed, the name must identify a prepared statement at the current server. The prepared statement cannot be a SELECT statement.

USING

Introduces a list of variables whose values are substituted for the parameter markers (question marks) in the prepared statement. For an explanation of parameter markers, see “[“PREPARE” on page 1236](#). If the prepared statement includes parameter markers, the USING clause must be used. USING is ignored if there are no parameter markers.

USING ALL or USING SUBSET

Identifies host structures or variables.

USING ALL

All the variables in the list are used for substitution of parameter markers in the prepared statement.

USING SUBSET

Some or all of the variables in the list are used for substitution of parameter markers in the prepared statement.

- Any host variable with an extended indicator value of UNASSIGNED will be removed from the list. The result is as if the host variable was not specified in the statement.
- All other indicator values have no special meaning to the EXECUTE statement.

When using this clause, a variable with an indicator value of UNASSIGNED cannot be used for substitution of parameter markers in the prepared statement.

variable,...

Identifies one or more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter marker in the prepared statement.

A global variable may only be used if the current connection is a local connection (not a DRDA connection).

SQL-descriptors

INTO

Identifies an SQL descriptor which contains valid descriptions of the output variables to be used with the EXECUTE statement. This clause is only valid for a CALL or VALUES INTO

statement. Before the EXECUTE statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

USING

Identifies an SQL descriptor which contains valid descriptions of the input variables to be used with the EXECUTE statement. Before the EXECUTE statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The information is returned from the descriptor known in this local scope.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information is returned from the descriptor known to any program that executes using the same database connection.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[SET DESCRIPTOR](#)” on page 1298 for an explanation of the information in the SQL descriptor.

DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of variables.

Before the EXECUTE statement is processed, the user must set the following fields in the SQLDA. (The rules for REXX are different. For more information, see the [Embedded SQL Programming](#) topic collection.)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the results, there must be additional SQLVAR entries for each parameter. For more information about the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The *n*th variable described by the SQLDA corresponds to the *n*th parameter marker in the prepared statement.

Note that RPG/400 does not provide the function for setting pointers. Because the SQLDA uses pointers to locate the appropriate variables, you have to set these pointers outside your RPG/400 application.

Notes

Parameter marker replacement: Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding variable. The replacement of a parameter marker is an assignment operation in which the source is the value of the variable, and the target is a variable within the database manager. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see [Table 125 on page 1244](#).

Let V denote a variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P using storage assignment rules as described in [“Assignments and comparisons” on page 83](#). Thus:

- V must be compatible with the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, the value of V must not be null.

However, unlike the storage assignment rules:

- If V is a string, the value will be truncated (without an error), if its length is greater than the length attribute of the target.

When the prepared statement is executed, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.

Examples

Example 1: This example of portions of a COBOL program shows how an INSERT statement with parameter markers is prepared and executed.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.  
    77 EMP          PIC X(6).  
    77 PRJ          PIC X(6).  
    77 ACT          PIC S9(4) COMP-4.  
    77 TIM          PIC S9(3)V9(2).  
01 HOLDER.  
    49 HOLDER-LENGTH  PIC S9(4) COMP-4.  
    49 HOLDER-VALUE   PIC X(80).  
EXEC SQL END DECLARE SECTION END-EXEC.  
. . .  
MOVE 70 TO HOLDER-LENGTH.  
MOVE "INSERT INTO EMPPROJECT (EMPNO, PROJNO, ACTNO, EMPTIME)  
      VALUES (?, ?, ?, ?)" TO HOLDER-VALUE.  
EXEC SQL PREPARE MYINSERT FROM :HOLDER END-EXEC.  
  
IF SQLCODE = 0  
  PERFORM DO-INSERT THRU END-DO-INSERT  
ELSE  
  PERFORM ERROR-CONDITION.  
  
DO-INSERT.  
  MOVE "000010" TO EMP.  
  MOVE "AD3100" TO PRJ.  
  MOVE 160      TO ACT.  
  MOVE .50      TO TIM.  
  EXEC SQL EXECUTE MYINSERT USING :EMP, :PRJ, :ACT, :TIM END-EXEC.  
END-DO-INSERT.  
. . .
```

Example 2: Code an update statement from optional pieces of text, then execute it using the host variables that apply to the generated statement.

Suppose there are two host variables with corresponding indicators:

```
PRED1HV and PRED1IND, a VARCHAR(50) variable  
PRED2HV and PRED2IND, a DECIMAL(10,2) variable
```

Build the statement based on selection conditions set by the application. This is pseudocode.

```
stmt = 'UPDATE MYTABLE SET STATUS = ''COMPLETE'' WHERE DATECOL = CURRENT DATE ';  
  
IF BUILD_PRED1 THEN  
  stmt = stmt CONCAT ' AND COL1 = ?';  
  PRED1HV = <specified value>;  
  PRED1IND = 0;  
ELSE  
  PRED1IND = -7;  
  
IF BUILD_PRED2 THEN  
  stmt = stmt CONCAT ' AND COL2 = ?';  
  PRED2HV = <specified value>;  
  PRED2IND = 0;  
ELSE  
  PRED2IND = -7;  
EXEC SQL PREPARE S1 FROM stmt;
```

The following EXECUTE statement can be used for any combination of generated predicates and will omit any host variables that have an indicator value of -7.

```
EXEC SQL EXECUTE S1 USING SUBSET :PRED1:PRED1IND, PRED2:PRED2IND;
```

If PREDIND1 has a value of -7, the EXECUTE statement is logically equivalent to:

```
EXEC SQL EXECUTE S1 USING PRED2:PRED2IND;
```

EXECUTE IMMEDIATE

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute SQL statements that contain neither variables nor parameter markers.

The EXECUTE IMMEDIATE statement:

- Prepares an executable form of an SQL statement from a character string form of the statement
- Executes the SQL statement

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

The authorization rules are those defined for the SQL statement specified by EXECUTE IMMEDIATE. For example, see “[INSERT](#)” on page 1200 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

The authorization ID of the statement is the run-time authorization ID unless DYNUSRPRF(*OWNER) was specified on the CRTSQLxxx command when the program was created. For more information, see “[Authorization IDs and authorization names](#)” on page 58.

Syntax

```
►► EXECUTE IMMEDIATE [variable] expression
```

Description

variable

Identifies a variable that must be declared in accordance with the rules for declaring character-string or Unicode graphic variables. An indicator variable must not be specified.

expression

An *expression* of the type described in “[Expressions](#)” on page 147, that does not include an aggregate function or column name. It must return a value that is a character string or a Unicode graphic string.

If a variable is specified in the *expression* it must not have a CCSID of 65535.¹⁰⁵

The value of the identified variable or expression is called a *statement string*.

The statement string must be one of the following SQL statements:¹⁰⁷

ALTER	LOCK TABLE	SET CURRENT IMPLICIT XMLPARSE OPTION
CALL	MERGE	SET CURRENT TEMPORAL SYSTEM_TIME
COMMENT	REFRESH TABLE	SET ENCRYPTION PASSWORD
COMMIT	RELEASE SAVEPOINT	SET PATH
Compound (dynamic)	RENAME	SET SCHEMA
CREATE	REVOKE	SET SESSION AUTHORIZATION
DECLARE GLOBAL TEMPORARY TABLE	ROLLBACK	SET TRANSACTION
DELETE	SAVEPOINT	SET variable ¹⁰⁶
DROP	SET CURRENT DEBUG MODE	TRANSFER OWNERSHIP
GRANT	SET CURRENT DECFLOAT ROUNDING MODE	TRUNCATE
INSERT	SET CURRENT DEGREE	UPDATE
LABEL		

The statement string must not:

- Begin with EXEC SQL.
- End with END-EXEC or a semicolon.
- Include references to variables. Global variables are allowed.
- Include parameter markers.

¹⁰⁵ In a PL/I program, a PL/I string expression can also be specified.

¹⁰⁶ The target of the SET variable statement must be a global variable.

¹⁰⁷ A *select-statement* is not allowed. To dynamically process a *select-statement*, use the PREPARE, DECLARE CURSOR, and OPEN statements.

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is not valid, it is not executed and the error condition that prevents its execution is reported in the stand-alone SQLSTATE and SQLCODE. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the stand-alone SQLSTATE and SQLCODE. Additional information about the error can be retrieved from the SQL Diagnostics Area (or the SQLCA).

Note

Performance considerations: If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

Example

Use C to execute the SQL statement in the variable Qstring.

```
void main ()
{
    EXEC SQL BEGIN DECLARE SECTION;

    char Qstring[100] = "INSERT INTO WORK_TABLE SELECT * FROM EMPPROJECT
    WHERE ACTNO >= 100";

    EXEC SQL END DECLARE SECTION;
    EXEC SQL INCLUDE SQLCA;
    .
    .
    .
    EXEC SQL EXECUTE IMMEDIATE :Qstring;
    return;
}
```

FETCH

The FETCH statement positions a cursor on a row of the result table. It can return zero, one, or multiple rows, and it assigns the values of the rows returned to variables.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not allowed in a REXX procedure.

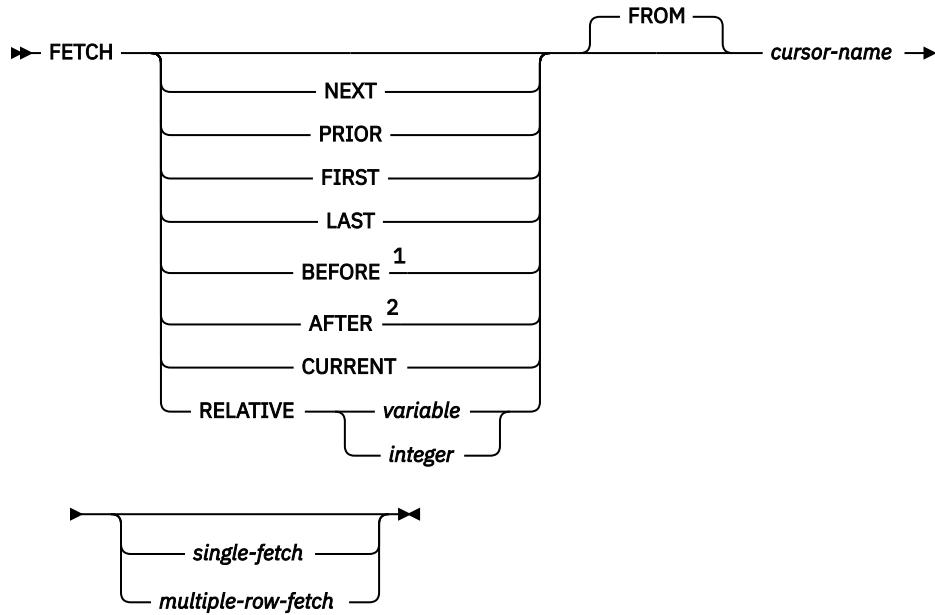

Authorization

See “[DECLARE CURSOR](#)” on page 1037 for an explanation of the authorization required to use a cursor.

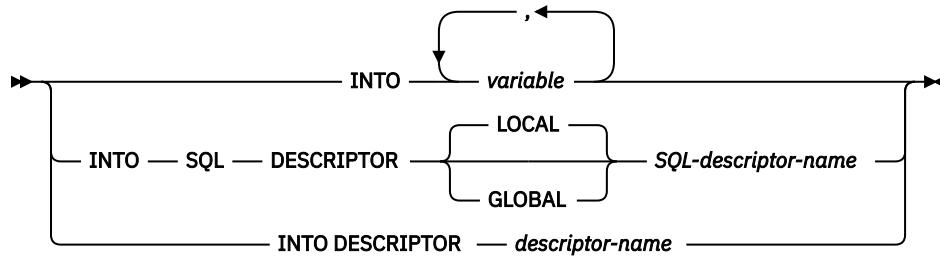

If a global variable is specified in the INTO variable list, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

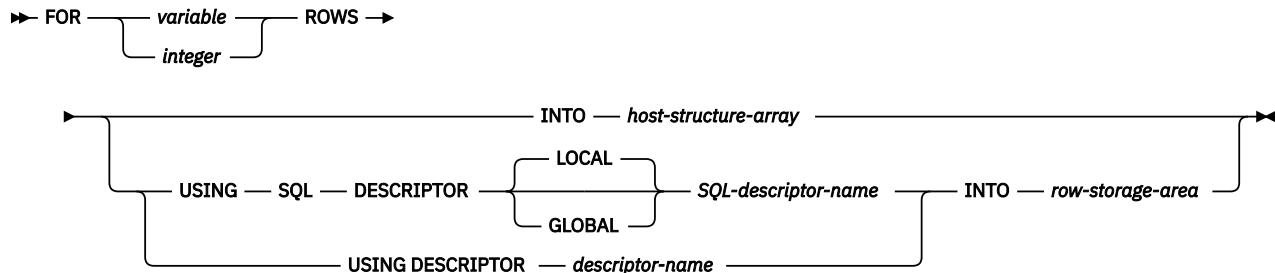

Syntax

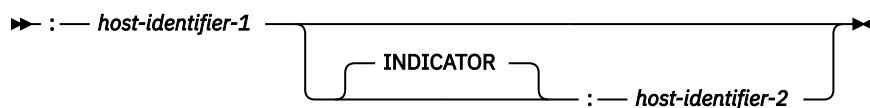

single-fetch

multiple-row-fetch

row-storage-area

Notes:

¹ If BEFORE is specified, a *single-fetch* or *multiple-row-fetch* must not be specified.

² If AFTER is specified, a *single-fetch* or *multiple-row-fetch* must not be specified.

Description

The following keywords specify a new position for the cursor: NEXT, PRIOR, FIRST, LAST, BEFORE, AFTER, CURRENT, and RELATIVE. Of those keywords, only NEXT may be used for cursors that have not been declared SCROLL.

NEXT

Positions the cursor on the next row of the result table relative to the current cursor position. NEXT is the default if no other cursor orientation is specified.

PRIOR

Positions the cursor on the previous row of the result table relative to the current cursor position.

FIRST

Positions the cursor on the first row of the result table.

LAST

Positions the cursor on the last row of the result table.

BEFORE

Positions the cursor before the first row of the result table.

AFTER

Positions the cursor after the last row of the result table.

CURRENT

Does not reposition the cursor, but maintains the current cursor position. If the cursor has been declared as DYNAMIC SCROLL and the current row has been updated so its place within the sort order of the result table is changed, an error is returned.

RELATIVE

Variable or *integer* is assigned to an integer value *k*. RELATIVE positions the cursor to the row in the result table that is either *k* rows after the current row if *k*>0, or *k* rows before the current row if *k*<0. If a *variable* is specified, it must be a numeric variable with zero scale and it must not include an indicator variable.

Table 100. Synonymous Scroll Specifications

Specification	Alternative
RELATIVE +1	NEXT
RELATIVE -1	PRIOR
RELATIVE 0	CURRENT

FROM

This keyword is provided for clarity only. If a scroll position option is specified, then this keyword is required. If no scrolling option is specified, then the FROM keyword is optional.

cursor-name

Identifies the cursor to be used in the fetch operation. The *cursor-name* must identify a declared cursor as explained in “Description” on page 1039 for the DECLARE CURSOR statement or when used in Java, an instance of an SQLJ iterator. When the FETCH statement is executed, the cursor must be in the open state.

If a *single-fetch* or *multiple-row-fetch* clause is not specified, no data is returned to the user. However, the cursor is positioned and a row lock may be acquired. For more information about locking, see “Isolation level” on page 23.

single-fetch**INTO *variable*...**

Identifies one or more host structures or variables that must be declared in accordance with the rules for declaring host structures and variables. In the operational form of INTO, a host structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on.

A global variable may only be used if the current connection is a local connection (not a DRDA connection).

INTO SQL DESCRIPTOR *SQL-descriptor-name*

Identifies an SQL descriptor which contains valid descriptions of the output variables to be used with the FETCH statement. Before the FETCH statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[SET DESCRIPTOR](#)” on page 1298 for an explanation of the information in the SQL descriptor.

INTO DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of zero or more variables.

Before the FETCH statement is processed, the user must set the following fields in the SQLDA. (The rules for REXX are different. For more information see the [Embedded SQL Programming](#) topic collection.)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to $16 + \text{SQLN}^*(80)$, where 80 is the length of an SQLVAR occurrence. If LOBs are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. For more information, see [Appendix D, “SQLDA \(SQL descriptor area\),”](#) on page 1439.

The USING DESCRIPTOR clause is not supported for a FETCH statement within a Java program.

multiple-row-fetch

FOR *variable* or *integer* ROWS

Evaluates *variable* or *integer* to an integral value that represents the number of rows to fetch. If a *variable* is specified, it must be a numeric variable with zero scale and it must not include an indicator variable. It must not be a global variable. The total size of the rows, excluding LOBs, must be less than 16M. The cursor is positioned on the row specified by the orientation keyword (for example, NEXT), and that row is fetched. Then the next rows are fetched (moving forward in the table), until either the specified number of rows have been fetched or the end of the cursor is reached. After the fetch operation, the cursor is positioned on the last row fetched.

For example, `FETCH PRIOR FROM C1 FOR 3 ROWS` causes the previous row, the current row, and the next row to be returned, in that order. The cursor is positioned on the next row. `FETCH RELATIVE -1 FROM C1 FOR 3 ROWS` returns the same result. `FETCH FIRST FROM C1 FOR :x ROWS` returns the first *x* rows, and leaves the cursor positioned on row number *x*.

When a *multiple-row-fetch* is successfully executed, three statement information items are available in the SQL Diagnostics Area (or the SQLCA):

- `ROW_COUNT` (or `SQLERRD(3)` of the SQLCA) shows the number of rows retrieved.
- `DB2_ROW_LENGTH` (or `SQLERRD(4)` of the SQLCA) contains the length of the row retrieved.
- `DB2_LAST_ROW` (or `SQLERRD(5)` of the SQLCA) contains +100 if the last row was fetched.¹⁰⁸

INTO host-structure-array

host-structure-array identifies an array of host structures defined in accordance with the rules for declaring host structures.

The first structure in the array corresponds to the first row, the second structure in the array corresponds to the second row, and so on. In addition, the first value in the row corresponds to the first item in the structure, the second value in the row corresponds to the second item in the structure, and so on. The number of rows to be fetched must be less than or equal to the dimension of the host structure array.

USING SQL DESCRIPTOR *SQL-descriptor-name*

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

The COUNT field in the descriptor header must be set to reflect the number of columns in the result set. The TYPE and DATETIME_INTERVAL_CODE (if applicable) must be set for each column in the result set.

USING DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of zero or more variables that describe the format of a row in the *row-storage-area*.

Before the FETCH statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of the variables.

The values of the other fields of the SQLDA (such as SQLNAME) may not be defined after the FETCH statement is executed and should not be used.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to $16 + \text{SQLN} * (80)$, where 80 is the length of an SQLVAR occurrence. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. For more information, see [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#).

On completion of the FETCH, the SQLDATA pointer in the first SQLVAR entry addresses the returned value for the first column in the allocated storage in the first row, the SQLDATA pointer in the second SQLVAR entry addresses the returned value for the second column in the allocated storage in the first row, and so on. The SQLIND pointer in the first nullable SQLVAR entry addresses the first indicator value, the SQLIND pointer in the second nullable SQLVAR entry addresses the second indicator value, and so on. The SQLDA must be allocated on a 16-byte boundary.

INTO *row-storage-area*

host-identifier-1 specified with a variable identifies an allocation of storage in which to return the rows. The rows are returned into the storage area in the format described by the SQLDA or SQL descriptor. *host-identifier-1* must be large enough to hold all the rows requested.

¹⁰⁸ If the number of rows returned is equal to the number of rows requested, then an end of data warning may not occur and DB2_LAST_ROW (or SQLERRD(5) of the SQLCA) may not contain +100.

host-identifier-2 identifies the optional indicator area. It should be specified if any of the data types returned are nullable. This variable identifies an allocation of storage in which to return the indicators. The indicators are returned as small integers. *host-identifier-2* must be large enough to contain an indicator for each nullable value for each row to be returned.

The GET DIAGNOSTICS statement can be used to return the DB2_ROW_LENGTH which indicates the length of each row returned into the *row-storage-area*.

The *nth* variable identified by the INTO clause or described in the SQLDA corresponds to the *nth* column of the result table of the cursor. The data type of each variable must be compatible with its corresponding column.

Each assignment to a variable is made according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88.¹⁰⁹ If the number of variables is less than the number of values in the row, the SQLSTATE is set to '01503' (or the SQLWARN3 field of the SQLCA is set to 'W'). Note that there is no warning if there are more variables than the number of result columns. If the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero, overflow, etc.) or a character conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, a warning is returned.) If you do not provide an indicator variable, an error is returned. It is possible that some values have already been assigned to variables and will remain assigned when the error occurs.

multiple-row-fetch is not allowed if any of the result columns are LOBs or if the current connection is to a remote server.

Notes

Cursor position: An open cursor has three possible positions:

- Before a row
- On a row
- After the last row

If a cursor is positioned on a row, that row is called the current row of the cursor. A cursor referenced in an UPDATE or DELETE statement must be positioned on a row. A cursor can only be positioned on a row as a result of a FETCH statement.

It is possible for an error to occur that makes the state of the cursor unpredictable.

Variable assignment: The *nth* variable identified by the INTO clause or described in the SQLDA corresponds to the *nth* column of the result table of the cursor. The data type of each variable must be compatible with its corresponding column.

Each assignment to a variable is made according to the Retrieval Assignment rules described in “[Assignments and comparisons](#)” on page 83. If the number of variables is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. Note that there is no warning if there are more variables than the number of result columns. If the value is null, an indicator variable must be provided. If an assignment error occurs, the values in the variables are unpredictable.

If the specified variable is a string and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result is returned in the indicator variable associated with the *variable*, if an indicator variable is provided.

¹⁰⁹ If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information on the standards option, see “[Standards compliance](#)” on page xix.

If the specified variable is a C NUL-terminated variable and is not large enough to contain the result and the NUL-terminator:

- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
 - The result is truncated.
 - The last character is the NUL-terminator.
 - A warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA).
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
 - The NUL-terminator is not returned.
 - A warning (SQLSTATE 01004) is returned (and 'N' is assigned to SQLWARN1 in the SQLCA).

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- USING DESCRIPTOR may be used as a synonym for INTO DESCRIPTOR in the single-fetch-clause.

Examples

Example 1: In this C example, the FETCH statement fetches the results of the SELECT statement into the program variables dnum, dname, and mnum. When no more rows remain to be fetched, the not found condition is returned.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT
  WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
while (SQLCODE==0) {
  EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;
}
EXEC SQL CLOSE C1;
```

Example 2: This FETCH statement uses an SQLDA.

```
FETCH CURS USING DESCRIPTOR :sqlda3
```

Example 3: This ILE RPG example uses a row storage area to fetch the data.

```
DCL-S ONE_ROW_PTR POINTER;
DCL-DS ONE_ROW BASED(ONE_ROW_PTR);
  DEPTNO  CHAR(3);
  DEPTNAME VARCHAR(36);
  MGRNO   CHAR(6);
END-DS;
DCL-S ONE_ROW_IND_PTR POINTER;

            ONE_ROW_IND_PTR = ONE_ROW_IND_PTR + %SIZE(ONE_ROW_IND);
        ENDFOR;

```

FREE LOCATOR

The FREE LOCATOR statement removes the association between a locator variable and its value.

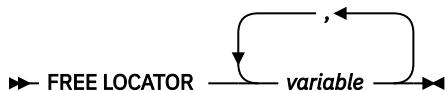

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

Description

variable...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, a double-byte character large object locator, or an XML locator.

The *variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a CALL, FETCH, SELECT INTO, assignment statement, SET variable, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator variable is specified and an error occurs on one of the locators, no locators will be freed.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. In a COBOL program, free the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC.

```

EXEC SQL
FREE LOCATOR :LOCRES, :LOCHIST, :LOCPIC
END-EXEC.

```

GET DESCRIPTOR

The GET DESCRIPTOR statement gets information from an SQL descriptor.

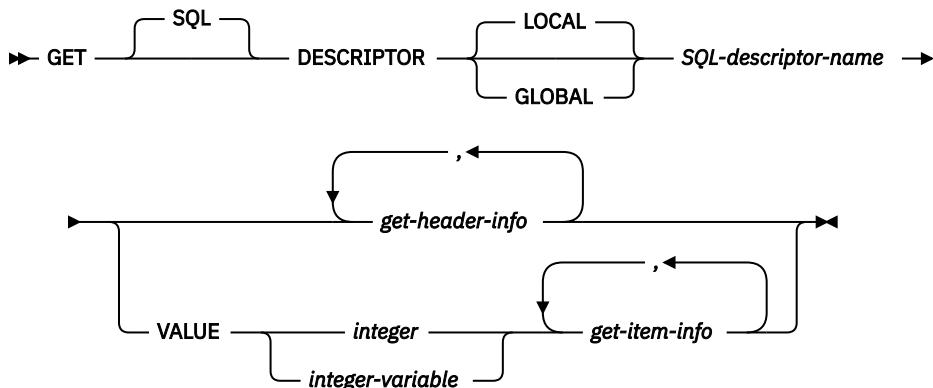

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

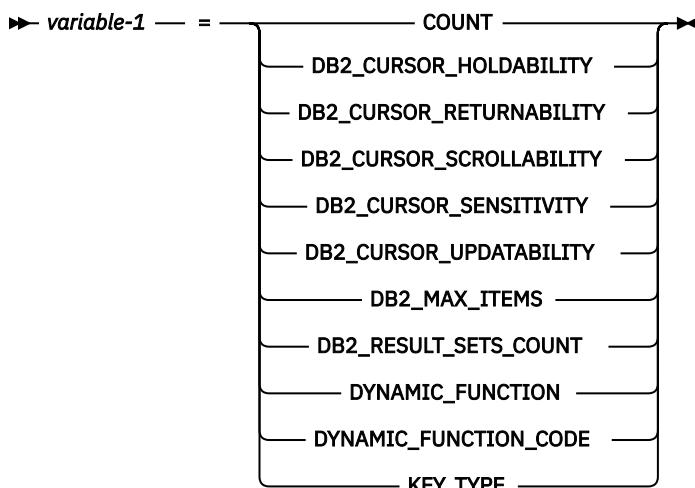

Authorization

None required.

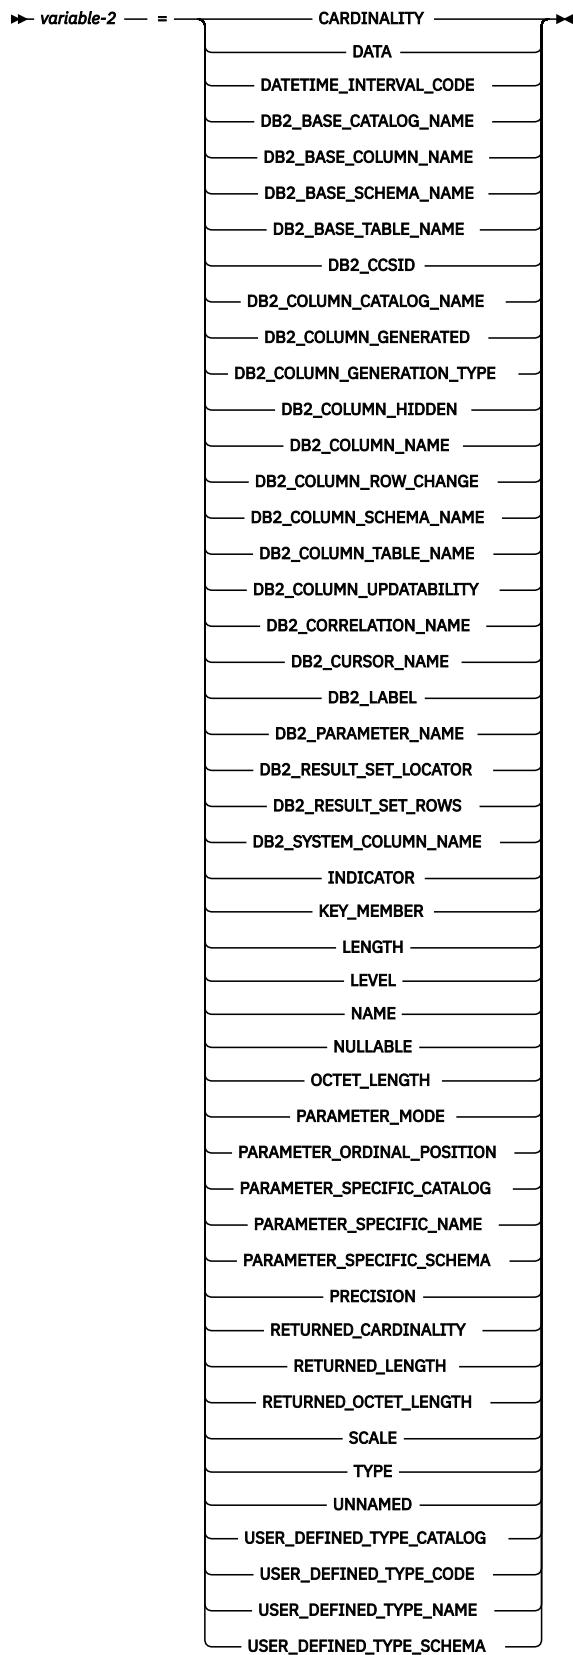

Syntax

get-header-info

get-item-info

Description

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The information is returned from the descriptor known in this local scope.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information is returned from the descriptor known to any program that executes using the same database connection.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

get-header-info

Returns information about the prepared SQL statement and SQL descriptor.

VALUE

Identifies the item number for which the specified information is retrieved. If the value is greater than the value of COUNT (from the header information), then no result is returned. If the item number is greater than the maximum number of items allocated for the descriptor or the item number is less than 1, an error is returned.

integer

An integer constant in the range of 1 to the number of items in the SQL descriptor.

integer-variable

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be SMALLINT, INTEGER, BIGINT, or DECIMAL or NUMERIC with a scale of zero. The value of *integer-variable* must be in the range of 1 to the maximum number of items in the SQL descriptor.

get-item-info

Returns information about a specific item in the SQL descriptor.

get-header-info

variable-1

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in [Table 101 on page 1141](#). The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#).

COUNT

A count of the number of items in the descriptor.

DB2_CURSOR_HOLDABILITY

The hold status of the cursor. The possible values are:

0

The descriptor is not describing a cursor or the cursor was not declared WITH HOLD.

1

The cursor was declared WITH HOLD.

DB2_CURSOR_RETURNABILITY

The return status of the cursor's result set. The possible values are:

0

The descriptor is not describing a cursor or the cursor's result set is not returnable.

1

The cursor's result set is returnable to the caller of the procedure.

2

The cursor's result set is returnable to the client.

DB2_CURSOR_SCROLLABILITY

The scroll status of the cursor. The possible values are:

0

The descriptor is not describing a cursor or the cursor was not declared with SCROLL.

1

The cursor was declared with SCROLL.

DB2_CURSOR_SENSITIVITY

The sensitivity of the cursor. The possible values are:

0

The descriptor is not describing a cursor.

1

The cursor is SENSITIVE DYNAMIC.

3

The cursor is INSENSITIVE.

4

The cursor is ASENSITIVE.

DB2_CURSOR_UPDATABILITY

Specifies whether the cursor can be used in an UPDATE statement with WHERE CURRENT OF *cursor-name*. The possible values are:

0

The descriptor is not describing a cursor or the cursor cannot be used in an UPDATE statement with WHERE CURRENT OF *cursor-name*.

1

The cursor can be used in an UPDATE statement with WHERE CURRENT OF *cursor-name*.

DB2_MAX_ITEMS

Represents the value specified as the allocated maximum number of item descriptors on the ALLOCATE DESCRIPTOR statement. If the WITH MAX clause was not specified, the value is the default number of maximum items for the ALLOCATE DESCRIPTOR statement.

DB2_RESULT_SETS_COUNT

The number of result sets returned by the procedure. The value will be 0 if this descriptor is not describing a procedure.

DYNAMIC_FUNCTION

The type of the prepared SQL statement as a character string. For information on statement type, see [Table 104 on page 1165](#).

DYNAMIC_FUNCTION_CODE

The statement code representing the type of the prepared SQL statement. For information on statement codes, see [Table 104 on page 1165](#).

KEY_TYPE

The type of key included in the select list. The possible values are:

0

The descriptor is not describing the columns of a query or there are no key columns referenced in the query, or there is no unique key.

1

The select list includes all the columns of the primary key of the base table referenced by the query.

2

The table referenced by the query does not have a primary key but the select list includes a set of columns that are defined as the preferred candidate key. If there is more than one such preferred candidate key included in the select list, the left-most preferred candidate key is used.

get-item-info

variable-2

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in [Table 101 on page 1141](#). The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see “[Assignments and comparisons](#)” on page 83.

When getting the DATA item, in general the variable must have the same data type, length, precision, scale, and CCSID as specified in [Table 101 on page 1141](#). For variable-length types, the variable length must not be less than the LENGTH in the descriptor. For C nul-terminated types, the variable length must be at least one greater than the LENGTH in the descriptor.

CARDINALITY

The cardinality of the array data type. If this descriptor is the result of a DESCRIBE, this is the maximum cardinality of the array data type. The cardinality is 0 for all other data types.

DATA

The value for the data described by the item descriptor. If the value of INDICATOR is negative, then the value of DATA is undefined and the INDICATOR *get-item-info* must also be specified in the same statement.

DATETIME_INTERVAL_CODE

Codes that define the specific datetime data type.

0

Descriptor item does not have TYPE value of 9.

1

DATE

2

TIME

3

TIMESTAMP

DB2_BASE_CATALOG_NAME

The server name of the base table for the column represented by the item descriptor.

DB2_BASE_COLUMN_NAME

The name of the column as defined in the base table referenced in the described query, possibly indirectly through a view. If a column name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_BASE_SCHEMA_NAME

The schema name of the base table for the column represented by the item descriptor. If a schema name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_BASE_TABLE_NAME

The table name of the underlying base table for the column represented by the item descriptor. If a table name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_CCSID

The CCSID of character, graphic, or XML data. Value is zero for all types that are not based on character or graphic string or XML types. Value is 65535 for binary types or character types with the FOR BIT DATA attribute.

DB2_COLUMN_CATALOG_NAME

The server name of the referenced table or view for the column represented by the item descriptor. If a column catalog name cannot be defined or is not applicable, this item will contain the empty string.

DB2_COLUMN_GENERATED

Indicates whether a column is generated. Possible values are:

- 0** Not generated
- 1** GENERATED ALWAYS
- 2** GENERATED BY DEFAULT

DB2_COLUMN_GENERATION_TYPE

Indicates how the column is generated. Possible values are:

- 0** Not generated
- 1** IDENTITY column
- 2** ROWID column
- 4** Row change timestamp column
- 5** ROW BEGIN column
- 6** ROW END column
- 7** TRANSACTION START ID column
- 8** Generated expression column

DB2_COLUMN_HIDDEN

Indicates whether the column represented by the item descriptor is hidden. Possible values are:

- 0** Not hidden
- 1** Implicitly hidden
- 3** Implicitly hidden for optimistic locking

DB2_COLUMN_NAME

The name of the column as defined in the table or view referenced in the described query. If a column name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_ROW_CHANGE

Indicates whether the column represented by the item descriptor was added as a result of using the WITH ROW CHANGE COLUMNS prepare attribute. Possible values are:

- 1** ROW CHANGE TOKEN (distinct)
- 2** ROW CHANGE TOKEN (not distinct)
- 3** RID (only valid from a remote relational database)
- 4** RID_BIT (only valid from a remote relational database)

DB2_COLUMN_SCHEMA_NAME

The schema name of the referenced table or view for the column represented by the item descriptor. If a column schema name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_TABLE_NAME

The table or view name of the referenced table or view for the column represented by the item descriptor. If a column table name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_UPDATABILITY

Indicates whether the column represented by the item descriptor is updatable. Possible values are:

0

Not updatable

1

Updatable

DB2_CORRELATION_NAME

The empty string is always returned.

DB2_CURSOR_NAME

The name of the cursor in the procedure for this result set. This is only set when the descriptor is describing a procedure.

DB2_LABEL

The label defined for the column. If there is no label for the column, this item will contain the empty string.

DB2_PARAMETER_NAME

The name of the parameter for the stored procedure. Only returned for a CALL statement. The name is returned as case sensitive and without delimiters.

DB2_RESULT_SET_LOCATOR

The result set locator for this result set. This is only set when the descriptor is describing a procedure.

DB2_RESULT_SET_ROWS

The estimated number of rows in the result set. It is set to the value -1 if the number is unknown. This is only set when the descriptor is describing a procedure.

DB2_SYSTEM_COLUMN_NAME

The system name of the column. If a system name cannot be defined or is not applicable, this item will contain blanks.

INDICATOR

The value for the indicator. A non-negative value is used when the value returned in this descriptor item is given in the DATA field. When extended indicator variables are not enabled, a negative value is used when the value returned in this descriptor item is the null value. When extended indicators are enabled:

- -1, -2, -3, -4, or -6 indicates the value returned in this descriptor is the null value.
- -5 indicates the value returned in this descriptor item is DEFAULT.
- -7 indicates the value returned in this descriptor item is UNASSIGNED.

KEY_MEMBER

An indication of whether this column is part of a key.

0

This column is not part of a key.

1

This column is part of a unique key.

2

This column by itself is a unique key.

LENGTH

Returns the maximum length of the data. If the data type is a character or graphic string, an XML type, or a datetime type, the length represents the number of characters (not bytes). If the data type is a binary string or any other type, the length represents the number of bytes. For a description of data type codes and lengths, see [Table 102 on page 1143](#).

LEVEL

The level of the item descriptor. The value is 0.

NAME

The name associated with the select list column described by the item descriptor. The name is returned as case sensitive and without delimiters.

NULLABLE

Indicates whether the column or parameter marker is nullable.

0

The select list column or parameter marker cannot have a null value.

1

The select list column or parameter marker can have a null value.

OCTET_LENGTH

Returns the maximum length of the data in bytes for all types. For a description of data type codes and lengths, see [Table 102 on page 1143](#).

PARAMETER_MODE

The mode of the parameter marker in a CALL statement.

0

The descriptor is not associated with a CALL statement.

1

Input only parameter.

2

Input and output parameter.

4

Output only parameter.

PARAMETER_ORDINAL_POSITION

The ordinal position of the parameter marker in a CALL statement. The value is 0 if the descriptor is not associated with a CALL statement.

PARAMETER_SPECIFIC_CATALOG

The server name of the procedure containing the parameter marker.

PARAMETER_SPECIFIC_NAME

The specific name of the procedure containing the parameter marker. The name is returned as case sensitive and without delimiters.

PARAMETER_SPECIFIC_SCHEMA

The schema name of the procedure containing the parameter marker. The name is returned as case sensitive and without delimiters.

PRECISION

Returns the precision for the data:

SMALLINT

4

INTEGER

9

BIGINT

19

NUMERIC and DECIMAL

Defined precision

REAL

24

DOUBLE

53

DECFLOAT(7)

7

DECFLOAT(16)

16

DECFLOAT(34)

34

TIME

0

TIMESTAMP

Defined precision (0-12)

Other data types

0

RETURNED_CARDINALITY

The current cardinality for an array data type returned by FETCH or CALL. The value is 0 when the data type of the item is not an array.

RETURNED_LENGTH

The returned length in characters for character string, graphic string, and XML data types. The returned length in bytes for binary string data types.

RETURNED_OCTET_LENGTH

The returned length in bytes for all string data types.

SCALE

Returns the defined scale if the data type is DECIMAL or NUMERIC. The scale is 0 for all other data types.

TYPE

Returns a data type code representing the data type of the item. For a description of the data type codes and lengths, see [Table 102 on page 1143](#).

UNNAMED

A value of 1 indicates that the NAME value is generated by the database manager. Otherwise, the value is zero and NAME is the derived name of the column in the select list.

USER_DEFINED_TYPE_CATALOG

The server name of the user-defined type. If the type is not a user-defined data type, this item contains the empty string.

USER_DEFINED_TYPE_CODE

Indicates whether the type of the descriptor item is a user-defined type.

0

The descriptor item is not a user-defined type.

1

The descriptor item is a strongly typed user-defined type.

101

The descriptor item is a weakly typed user-defined type.

USER_DEFINED_TYPE_NAME

The name of the user-defined data type. If the type is not a user-defined data type, this item contains the empty string. The name is returned as case sensitive and without delimiters.

USER_DEFINED_TYPE_SCHEMA

The schema name of the user-defined data type. If the type is not a user-defined data type, this item contains the empty string. The name is returned as case sensitive and without delimiters.

Notes

Data types for items: The following table shows the SQL data type for each descriptor item. When a descriptor item is assigned to a variable, the variable must be compatible with the data type of the descriptor item.

Table 101. Data Types for GET DESCRIPTOR Items	
Item Name	Data Type
Header Information	
COUNT	INTEGER
DB2_CURSOR_HOLDABILITY	INTEGER
DB2_CURSOR_RETURNABILITY	INTEGER
DB2_CURSOR_SCROLLABILITY	INTEGER
DB2_CURSOR_SENSITIVITY	INTEGER

PARAMETER_SPECIFIC_NAME	VARCHAR(128)
PARAMETER_SPECIFIC_SCHEMA	VARCHAR(128)
PRECISION	INTEGER
RETURNED_CARDINALITY	INTEGER
RETURNED_LENGTH	INTEGER
RETURNED_OCTET_LENGTH	INTEGER
SCALE	INTEGER
TYPE	INTEGER
UNNAMED	INTEGER
USER_DEFINED_TYPE_CATALOG	VARCHAR(128)
USER_DEFINED_TYPE_NAME	VARCHAR(128)
USER_DEFINED_TYPE_SCHEMA	VARCHAR(128)
USER_DEFINED_TYPE_CODE	VARCHAR(128)

SQL data type codes and lengths: The following table represents the possible values for TYPE, LENGTH, OCTET_LENGTH, and DATETIME_INTERVAL_CODE descriptor items.

The values in the following table are assigned by the ISO and ANSI SQL Standard and may change as the standard evolves. Include `sqlscds` in the include source files in library QSYSINC should be used when referencing these values.

Table 102. SQL Data Type Codes and Lengths

Data Type	Data Type Code	Length	Octet Length
SMALLINT	5	2	2
INTEGER	4	4	4
BIGINT	25	8	8
DECIMAL	3	(precision/2)+1	(precision/2)+1
NUMERIC(n)	2	n	n
REAL	7	4	4
FLOAT	6	8	8
DOUBLE PRECISION	8	8	8
DECFLOAT(7)	-360	4	4
DECFLOAT(16)	-360	8	8
DECFLOAT(34)	-360	16	16
CHARACTER(n)	1	n	n
VARCHAR(n)	12	<=n	n
CLOB(n)	40	<=n	n
GRAPHIC(n)	-95	n	2*n
VARGRAPHIC(n)	-96	<=n	2*n
DBCLOB(n)	-350	<=n	2*n
BINARY(n)	-2	n	n
VARBINARY(n)	-3	<=n	n
BLOB(n)	30	n	n
DATE (DATETIME_INTERVAL_CODE = 1)	9	Length depends on date format	Based on CCSID
TIME (DATETIME_INTERVAL_CODE = 2)	9	Length depends on time format	Based on CCSID
TIMESTAMP (DATETIME_INTERVAL_CODE = 3)	9	19-32, depending on precision	19-32 or 38-64, depending on precision (based on CCSID)
DATALINK(n)	70	<=n	n
ROWID	-904	40	40
XML	137	0	0
C nul terminated CHARACTER(n)	1	<=n	n
C nul terminated GRAPHIC(n)	-400	<=n	2*n
BLOB File Reference Variable	-916	267	267
CLOB File Reference Variable	-920	267	267
DBCLOB File Reference Variable	-924	267	267

Table 102. SQL Data Type Codes and Lengths (continued)

Data Type	Data Type Code	Length	Octet Length
Result Set Locator	-972	8	8
Array	50	N/A	N/A

Example

Example 1: Retrieve from the descriptor 'NEWDA' the number of descriptor items.

```
EXEC SQL GET DESCRIPTOR 'NEWDA'
: numitems = COUNT;
```

Example 2: Retrieve from the first item descriptor of descriptor 'NEWDA' the data type and the octet length.

```
GET DESCRIPTOR 'NEWDA'
  VALUE 1 :dtype = TYPE,
        :olength = OCTET_LENGTH;
```

GET DIAGNOSTICS

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

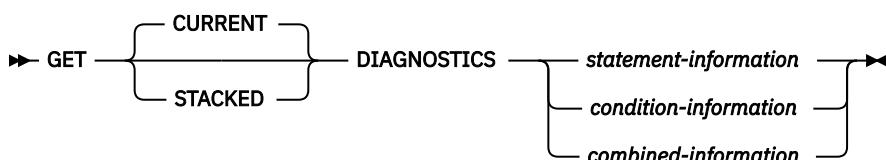

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

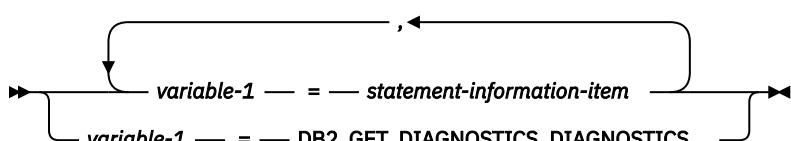

Authorization

None required.

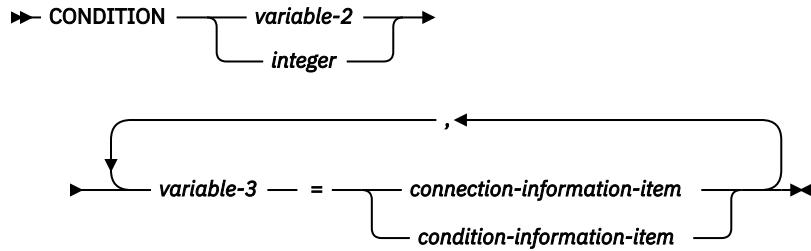

Syntax

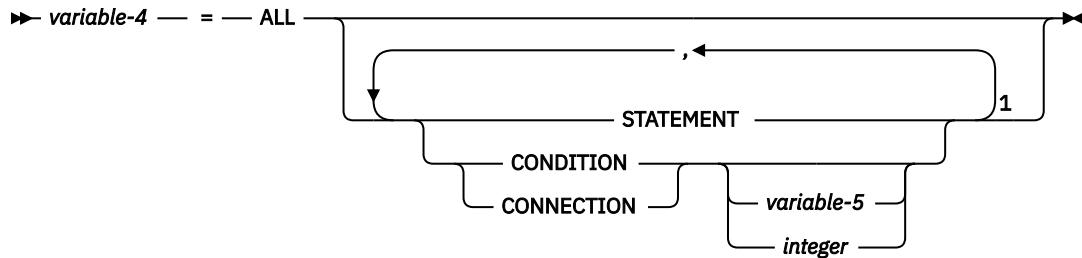

statement-information

Description

CURRENT or STACKED

Specifies which diagnostics area to access.

CURRENT

Specifies to access the first diagnostics area. It corresponds to the previous SQL statement that was executed and that was not a GET DIAGNOSTICS statement. This is the default.

STACKED

Specifies to access the second diagnostics area. The second diagnostics area is only available within a handler. It corresponds to the previous SQL statement that was executed before the handler was entered and that was not a GET DIAGNOSTICS statement. If the GET DIAGNOSTICS statement is the first statement within a handler, then the first diagnostics area and the second diagnostics area contain the same diagnostics information.

statement-information

Returns information about the last SQL statement executed.

variable-1

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be compatible with the data type as specified in [Table 103 on page 1162](#) for the specified condition information item. The variable is assigned the value of the specified statement information item according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88. If the value is truncated when assigning it to the variable, a warning (SQLSTATE 01004) is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the variable is set to a default value based on its data type:

- 0 for an exact numeric diagnostic item,
- an empty string for a VARCHAR diagnostic item,
- and blanks for a CHAR diagnostic item.

condition-information

Returns information about the condition or conditions that occurred when the last SQL statement was executed.

CONDITION variable-2 or integer

Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic and so on. When the value is 1, the diagnostic information corresponds to the condition indicated by the SQLSTATE value returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). Values of 2 to n represent other conditions that were reported while executing the SQL statement. The value of 2 is the earliest condition that occurred, with each additional value happening later in time.

The variable specified must be declared in the program in accordance with the rules for declaring exact numeric variables with zero scale. It must not be a global variable. The value specified must not be less than one or greater than the number of available diagnostics.

variable-3

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be compatible with the data type as specified in [Table 103 on page 1162](#) for the specified condition information item. The variable is assigned the value of the specified condition information item according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88. If the value is truncated when assigning it to the variable, an error is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the variable is set to a default value based on its data type:

- 0 for an exact numeric diagnostic item,
- an empty string for a VARCHAR diagnostic item,

- and blanks for a CHAR diagnostic item.

combined-information

Returns multiple information items combined into one string.

variable-4

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be VARCHAR. The variable is assigned according to the retrieval assignment rules described in “Retrieval assignment” on page 88. If the length of *variable-4* is not sufficient to hold the full returned diagnostic string, the string is truncated, an error is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

ALL

Indicates that all diagnostic items that are set for the last SQL statement executed should be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form:

```
item-name=character-form-of-the-item-value;
```

The character form of a positive numeric value will not contain a leading plus sign (+) unless the item is DB2_RETURNED_SQLCODE. In this case, a leading plus sign (+) is added. For example:

```
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
```

Only items that contain diagnostic information are included in the string. There are also no entries in this string for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS and DB2_SQL_NESTING_LEVEL items.

STATEMENT

Indicates that all *statement-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. The format is the same as described above for ALL.

CONDITION

Indicates that *condition-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If *variable-5* or *integer* is specified, then the format is the same as described above for the ALL option. If *variable-5* or *integer* is not specified, then the format includes a condition number entry at the beginning of the information for that condition in the form:

```
CONDITION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

CONNECTION

Indicates that *connection-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If *variable-5* or *integer* is specified, then the format is the same as described above for ALL. If *variable-5* or *integer* is not specified, then the format includes a connection number entry at the beginning of the information for that condition in the form:

```
DB2_CONNECTION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
DB2_CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN07010;
```

variable-5 or integer

Identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The variable specified must be declared in the program in accordance with the rules for declaring integer variables. It must not be a global variable. The value specified must not be less than one or greater than the number of available diagnostics.

statement-information-item**COMMAND_FUNCTION**

Returns the name of the previous SQL statement. For information about the statement string values, see [Table 104 on page 1165](#).

COMMAND_FUNCTION_CODE

Returns an integer that identifies the previous SQL statement. For information about the statement code values, see [Table 104 on page 1165](#).

DB2_DIAGNOSTIC_CONVERSION_ERROR

Returns the value 1 if there was a conversion error when converting a character data value for one of the GET DIAGNOSTICS statement values. Otherwise, the value zero is returned.

DB2_GET_DIAGNOSTICS_DIAGNOSTICS

After a GET DIAGNOSTICS statement, if any errors or warnings occurred during the execution of the GET DIAGNOSTICS statement, DB2_GET_DIAGNOSTICS_DIAGNOSTICS returns textual information about these errors or warnings. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

If a request was made for an information item that the server does not understand, for example, if the server was at a lower DRDA level than the requesting client, DB2_GET_DIAGNOSTICS_DIAGNOSTICS returns the text 'Item not supported:' followed by a comma separated list of item names that were requested but that the server does not support.

DB2_LAST_ROW

For a *multiple-row-fetch* statement, a value of +100 might be returned if the set of rows that have been fetched contains the last row currently in the result table for cursors that are fetching forward, or contains the first row currently in the result table, for cursors that are fetching backward. If the number of rows returned is equal to the number of rows requested, then an end of data warning may not occur and DB2_LAST_ROW may not contain +100.

If a value of +100 for DB2_LAST_ROW is returned for a cursor that is not sensitive to updates, a subsequent FETCH would return with the SQLCODE set to +100 and SQLSTATE set to '02000'. For a cursor that is sensitive to updates, a subsequent FETCH might return more data if any rows have been inserted before the FETCH was executed.

For statements other than *multiple-row-fetch* statements, for *multiple-row-fetch* statements that do not contain the last row currently in the result table, for cursors that are fetching forwards, or that do not contain the first row currently in the result table, for cursors that are fetching backwards, or if the server only returns an SQLCA, the value zero is returned.

DB2_NUMBER_CONNECTIONS

Returns the number of connections that were made in order to get to the server that fulfilled the request from the client. Each such connection may generate a connection information item area which would be available for the single condition.

DB2_NUMBER_PARAMETER_MARKERS

For a PREPARE statement, returns the number of parameter markers in the prepared statement. Otherwise, the value zero is returned.

DB2_NUMBER_RESULT_SETS

For a CALL statement, returns the actual number of result sets returned by the procedure. Otherwise, the value zero is returned.

DB2_NUMBER_ROWS

If the previous SQL statement was an OPEN or a FETCH which caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE cursors, this value can be

thought of as an approximation since rows inserted and deleted will affect the next retrieval of this value. Otherwise, the value zero is returned.

DB2_NUMBER_SUCCESSFUL_STMTS

For embedded compound SQL statements, returns a count of the number of successful sub-statements. Otherwise, the value zero is returned.

DB2_RELATIVE_COST_ESTIMATE

For a PREPARE statement, returns a relative cost estimate of the resources required for every execution. It does not reflect an estimate of the time required. When preparing a dynamically defined statement, this value can be used as an indicator of the relative cost of the prepared statement. The value varies depending on changes to statistics and can vary between releases of the product. It is an estimated cost for the access plan chosen by the optimizer. The value zero is returned if the statement is not a PREPARE statement.

DB2_RETURN_STATUS

Identifies the status value returned from the previous SQL CALL statement. If the previous statement is not a CALL statement, the value returned has no meaning and is unpredictable. For more information, see [“RETURN statement” on page 1405](#). Otherwise, the value zero is returned.

For external procedures, if the returned SQLCODE < 0, the SQL_ERROR_CODE1 and DB2_RETURN_STATUS will be set to -1, otherwise SQL_ERROR_CODE1 and DB2_RETURN_STATUS are set to 0.

DB2_ROW_COUNT_SECONDARY

Identifies the number of rows associated with secondary actions from the previous SQL statement that was executed. If the previous SQL statement is a DELETE or MERGE, the value is the total number of rows affected by referential constraints, including cascaded actions and the processing of triggered SQL statements from activated triggers. If the previous SQL statement is an INSERT or an UPDATE, the value is the total number of rows affected as the result of the processing of triggered SQL statements from activated triggers. Otherwise, the value zero is returned.

If the SQL statement is run using isolation level No Commit, this value may be zero.

DB2_ROW_LENGTH

For FETCH, if the result row does not contain a LOB, returns the length of the row(s) retrieved. For OPEN, if the result row does not contain a LOB, returns the length of a result row. For FETCH and OPEN, if the result does contain a LOB, the length returned is unpredictable. Otherwise, the value zero is returned.

DB2_SQL_ATTR_CONCURRENCY

For an OPEN statement, indicates the concurrency control option of read-only, locking, optimistic using timestamps, or optimistic using values.

- R indicates read-only.
- L indicates locking.
- T indicates comparing row versions using timestamps or ROWIDs.
- V indicates comparing values.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_CAPABILITY

For an OPEN statement, indicates the capability of the cursor, whether a cursor is read-only, deletable, or updatable.

- R indicates that this cursor can only be used to read.
- D indicates that this cursor can be used to read as well as delete.
- U indicates that this cursor can be used to read, delete as well as update.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_HOLD

For an OPEN statement, indicates whether a cursor can be held open across multiple units of work or not.

- N indicates that this cursor will not remain open across multiple units of work.
 - Y indicates that this cursor will remain open across multiple units of work.
- Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_ROWSET

For an OPEN statement, whether a cursor can be accessed using rowset positioning or not.

- N indicates that this cursor only supports row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_SCROLLABLE

For an OPEN statement, indicates whether a cursor can be scrolled forward and backward or not.

- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_SENSITIVITY

For an OPEN statement, indicates whether a cursor does or does not show updates to cursor rows made by other connections.

- I indicates insensitive.
- P indicates partial sensitivity.
- S indicates sensitive.
- U indicates unspecified.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_TYPE

For an OPEN statement, indicates whether a cursor type is dynamic, forward-only, or static.

- D indicates a dynamic cursor.
- F indicates a forward-only cursor.
- S indicates a static cursor.

Otherwise, a blank is returned.

DB2_SQL_NESTING_LEVEL

Identifies the current level of nesting or recursion in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of a function, procedure, or trigger. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value zero is returned.

If GET DIAGNOSTICS is issued in a user-defined function that is running in parallel, the nesting level is not predictable.

DYNAMIC_FUNCTION

Returns a character string that identifies the type of the SQL-statement being prepared or executed dynamically. For information about the statement string values, see [Table 104 on page 1165](#).

DYNAMIC_FUNCTION_CODE

Returns a number that identifies the type of the SQL-statement being prepared or executed dynamically. For information about the statement code values, see [Table 104 on page 1165](#).

MORE

Indicates whether more errors were raised than could be handled.

- N indicates that all the errors and warnings from the previous SQL statement were stored in the diagnostics area.
- Y indicates that more errors and warnings were raised from the previous SQL statement than there are condition areas in the diagnostics area. The maximum size of the diagnostics area is 90K.

NUMBER

Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL statement returned success (SQLSTATE 00000), or no previous SQL statement has been executed, the number returned is one. The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS item.

ROW_COUNT

Identifies the number of rows associated with the previous SQL statement that was executed. If the previous SQL statement is a DELETE, INSERT, REFRESH, or UPDATE statement, ROW_COUNT identifies the number of rows deleted, inserted, or updated by that statement, excluding rows affected by either triggers or referential integrity constraints. If the previous SQL statement is a MERGE statement, ROW_COUNT identifies the total number of rows deleted, inserted, and updated by that statement, excluding rows affected by either triggers or referential integrity constraints. If the previous SQL statement is a *multiple-row-fetch*, ROW_COUNT identifies the number of rows fetched. Otherwise, the value zero is returned.

TRANSACTION_ACTIVE

Returns the value 1 if an SQL transaction is currently active, and 0 if an SQL transaction is not currently active.

TRANSACTIONS_COMMITED

If the previous statement was a CALL, returns the number of transactions that were committed during the execution of the SQL or external procedure. Otherwise, the value zero is returned.

TRANSACTIONS_ROLLED_BACK

If the previous statement was a CALL, returns the number of transactions that were rolled back during the execution of the SQL or external procedure. Otherwise, the value zero is returned.

connection-information-item**CONNECTION_NAME**

If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION, returns the name of the server specified in the previous statement. Otherwise, the name of the current connection.

DB2_AUTHENTICATION_TYPE

Indicates the authentication type, whether server or client.

- C for client authentication.
- E for DCE security services authentication.
- S for server authentication.

Otherwise, a blank is returned.

DB2_AUTHORIZATION_ID

Returns the authorization id used by connected server. Because of userid translation and authorization exits, the local userid may not be the authid used by the server.

DB2_CONNECTION_METHOD

For a CONNECT or SET CONNECTION statement, returns the connection method.

- D indicates *DUW (Distributed Unit of Work).
- R indicates *RUW (Remote Unit of Work).

DB2_CONNECTION_NUMBER

Returns the number of the connections.

DB2_CONNECTION_STATE

Indicates the connection state, whether connected or not.

- -1 indicates the connection is unconnected.
- 1 indicates the connection is connected.

Otherwise, the value zero is returned.

DB2_CONNECTION_STATUS

Indicates whether committable update can be performed or not.

- 1 indicates committable updates can be performed on the connection for this unit of work.
- 2 indicates no committable updates can be performed on the connection for this unit of work.

Otherwise, the value zero is returned.

DB2_CONNECTION_TYPE

Indicated the connection type (either local, remote, or to a driver program) and whether the conversation is protected or not.

- 1 indicates a connection to a local relational database.
- 2 indicates a connection to a remote relational database with the conversation unprotected.
- 3 indicates a connection to a remote relational database with the conversation protected.
- 4 indicates a connection to an application requester driver program.

Otherwise, the value zero is returned.

DB2_DYN_QUERY_MGMT

Returns a value of 1 if DYN_QUERY_MGMT database configuration parameter is enabled. Otherwise, the value zero is returned.

DB2_ENCRYPTION_TYPE

Returns the level of encryption.

- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.

Otherwise, a blank is returned.

DB2_PRODUCT_ID

Returns a product signature. If the application server is an IBM relational database product, the form is pppvrrm, where:

- ppp identifies the product as follows: ARI for Db2 for VM and VSE, DSN for Db2 for z/OS, QSQ for Db2 for i, and SQL for all other Db2 products
- vv is a two-digit version identifier such as '04'
- rr is a two-digit release identifier such as '01'
- m is a one-digit modification level such as '0'

For example, if the application server is Version 7 of Db2 for z/OS, the value would be 'DSN07010'. Otherwise, the empty string is returned.

DB2_SERVER_CLASS_NAME

Returns the server class name. For example, Db2 for z/OS, Db2 for AIX, Db2 for Windows, and Db2 for i.

DB2_SERVER_NAME

For a CONNECT or SET CONNECTION statement, returns the relational database name. Otherwise, the empty string is returned.

condition-information-item**CATALOG_NAME**

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

and the constraint that caused the error is a referential, check, or unique constraint, the server name of the table that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned. Otherwise, the empty string is returned.

CLASS_ORIGIN

Returns 'ISO 9075' for those SQLSTATEs whose class is defined by ISO 9075. Returns 'ISO/IEC 13249' for those SQLSTATEs whose class is defined by SQL/MM. Returns 'DB2 SQL' for those SQLSTATEs whose class is defined by IBM Db2 SQL. Returns the value set by user written code if available. Otherwise, the empty string is returned.

COLUMN_NAME

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation) and the error was caused by an inaccessible column, the name of the column that caused the error is returned. Otherwise, the empty string is returned.

CONDITION_IDENTIFIER

If the value of the RETURNED_SQLSTATE corresponds to an unhandled user-defined exception (SQLSTATE 45000), then the condition name of the user-defined exception is returned.

CONDITION_NUMBER

Returns the number of the conditions.

CONSTRAINT_CATALOG

If the returned SQLSTATE is:

- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the server that contains the table that contains the constraint that caused the error is returned. Otherwise, the empty string is returned.

CONSTRAINT_NAME

If the returned SQLSTATE is:

- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the constraint that caused the error is returned. Otherwise, the empty string is returned.

CONSTRAINT_SCHEMA

If the returned SQLSTATE is:

- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the schema of the constraint that caused the error is returned. Otherwise, the empty string is returned.

CURSOR_NAME

If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

DB2_ERROR_CODE1

Returns an internal error code. Otherwise, the value zero is returned.

DB2_ERROR_CODE2

Returns an internal error code. Otherwise, the value zero is returned.

DB2_ERROR_CODE3

Returns an internal error code. Otherwise, the value zero is returned.

DB2_ERROR_CODE4

Returns an internal error code. Otherwise, the value zero is returned.

DB2_INTERNAL_ERROR_POINTER

For some errors, this will be a negative value that is an internal error pointer. Otherwise, the value zero is returned.

DB2_LINE_NUMBER

For a CREATE PROCEDURE for an SQL function, SQL procedure, or SQL trigger where an error is encountered parsing the SQL procedure body, returns the line number where the error possibly occurred. Otherwise, the value zero is returned.

DB2_MESSAGE_ID

Returns the message ID corresponding to the MESSAGE_TEXT.

DB2_MESSAGE_ID1

Returns the underlying IBM i CPF escape message that originally caused this error. Otherwise, the empty string is returned.

DB2_MESSAGE_ID2

Returns the underlying IBM i CPD diagnostic message that originally caused this error. Otherwise, the empty string is returned.

DB2_MESSAGE_KEY

For a CALL statement, returns the IBM i message key of the error that caused the procedure to fail. For a trigger error in a DELETE, INSERT, or UPDATE statement, returns the message key of the error that was signaled from the trigger program. The IBM i QMHRCVPM API can be used to return the message description and message data for the message key. Otherwise, the value zero is returned.

DB2_MODULE_DETECTING_ERROR

Returns an identifier indicating which module detected the error. For a SIGNAL statement issued from a routine, the value 'ROUTINE' is returned. For other SIGNAL statements, the value 'PROGRAM' is returned.

DB2_NUMBER FAILING STATEMENTS

For a NOT ATOMIC embedded compound SQL statement, returns the number of statements that failed. Otherwise, the value zero is returned.

DB2_OFFSET

For a CREATE PROCEDURE for an SQL procedure where an error is encountered parsing the SQL procedure body, returns the offset into the line number where the error possibly occurred, if available. For an EXECUTE IMMEDIATE or a PREPARE statement where an error is encountered parsing the source statement, returns the offset into the source statement where the error possibly occurred. Otherwise, the value zero is returned.

DB2_ORDINAL_TOKEN_n

Returns the nth token. n must be a value from 1 to 100. For example, DB2_ORDINAL_TOKEN_1 would return the value of the first token, DB2_ORDINAL_TOKEN_2 the second token. A numeric value for a token is converted to character before being returned. If there is no value for the token, the empty string is returned.

DB2_PARTITION_NUMBER

For a partitioned database, returns the partition number of the database partition that encountered the error or warning. If no errors or warnings were encountered, returns the partition number of the current node. Otherwise, the value zero is returned.

DB2_REASON_CODE

Returns the reason code for errors that have a reason code token in the message text. Otherwise, the value zero is returned.

DB2_RETURNED_SQLCODE

Returns the SQLCODE for the specified diagnostic.

DB2_ROW_NUMBER

If the previous SQL statement is a multiple row insert or a multiple row fetch, returns the number of the row where the condition was encountered, when such a value is available and applicable. Otherwise, the value zero is returned.

DB2_SQLERRD_SET

Returns Y to indicate that the DB2_SQLERRD1 through DB2_SQLERRD6 items may be set. Otherwise, a blank is returned.

DB2_SQLERRD1

Returns the value of SQLERRD(1) from the SQLCA returned by the server.

DB2_SQLERRD2

Returns the value of SQLERRD(2) from the SQLCA returned by the server.

DB2_SQLERRD3

Returns the value of SQLERRD(3) from the SQLCA returned by the server.

DB2_SQLERRD4

Returns the value of SQLERRD(4) from the SQLCA returned by the server.

DB2_SQLERRD5

Returns the value of SQLERRD(5) from the SQLCA returned by the server.

DB2_SQLERRD6

Returns the value of SQLERRD(6) from the SQLCA returned by the server.

DB2_TOKEN_COUNT

Returns the number of tokens available for the specified diagnostic.

DB2_TOKEN_STRING

Returns a X'FF' delimited string of the tokens for the specified diagnostic.

MESSAGE_LENGTH

Identifies the length (in characters) of the message text of the error, warning, or successful completion returned from the previous SQL statement that was executed.

MESSAGE_OCTET_LENGTH

Identifies the length (in bytes) of the message text of the error, warning, or successful completion returned from the previous SQL statement that was executed.

MESSAGE_TEXT

Identifies the message text of the error, warning, or successful completion returned from the previous SQL statement that was executed.

When the SQLCODE is 0, the empty string is returned, even if the RETURNED_SQLSTATE value indicates a warning condition.

PARAMETER_MODE

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition is related to the *i*th parameter of the routine, the parameter mode of the *i*th parameter is returned. Otherwise, the empty string is returned.

PARAMETER_NAME

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or

- class 2F (SQL Routine Exception), or
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

the condition is related to the *i*th parameter of the routine, and a parameter name was specified for the parameter when the routine was created, the parameter name of the *i*th parameter is returned. Otherwise, the empty string is returned.

PARAMETER_ORDINAL_POSITION

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition is related to the *i*th parameter of the routine, the value of *i* is returned. Otherwise, the empty string is returned.

RETURNED_SQLSTATE

Returns the SQLSTATE for the specified diagnostic.

ROUTINE_CATALOG

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the *i*th parameter of the routine, or if the returned SQLSTATE is:

- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the server name of the routine is returned. Otherwise, the empty string is returned.

ROUTINE_NAME

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the *i*th parameter of the routine, or if the returned SQLSTATE is:

- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the name of the routine is returned. Otherwise, the empty string is returned.

ROUTINE_SCHEMA

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or

- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the *i*th parameter of the routine, or if the returned SQLSTATE is:

- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the schema name of the routine is returned. Otherwise, the empty string is returned.

SCHEMA_NAME

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

and the constraint that caused the error is a referential, check, or unique constraint, the schema name of the table that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the schema name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the schema name of the view that caused the error is returned. Otherwise, the empty string is returned.

SERVER_NAME

If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION, the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executed is returned.

SPECIFIC_NAME

If the returned SQLSTATE is:

- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the *i*th parameter of the routine, or if the returned SQLSTATE is:

- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the specific name of the procedure or function is returned. Otherwise, the empty string is returned.

SUBCLASS_ORIGIN

Returns 'ISO 9075' for those SQLSTATEs whose subclass is defined by ISO 9075. Returns 'ISO/IEC 9579' for those SQLSTATEs whose subclass is defined by RDA. Returns 'ISO/IEC 13249-1', 'ISO/IEC 13249-2', 'ISO/IEC 13249-3', 'ISO/IEC 13249-4', or 'ISO/IEC 13249-5' for those SQLSTATEs whose subclass is defined SQL/MM. Returns 'DB2 SQL' for those SQLSTATEs whose subclass is defined by IBM Db2 SQL. Returns the value set by user written code if available. Otherwise, the empty string is returned.

TABLE_NAME

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or

- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

and the constraint that caused the error is a referential, check, or unique constraint, the table name that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the table name that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the table name that caused the error is returned. Otherwise, the empty string is returned.

TRIGGER_CATALOG

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or
- class 27 (Triggered Data Change Violation),

the name of the trigger is returned. Otherwise, the empty string is returned.

TRIGGER_NAME

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or
- class 27 (Triggered Data Change Violation),

the name of the trigger is returned. Otherwise, the empty string is returned.

TRIGGER_SCHEMA

If the returned SQLSTATE is:

- class 09 (Triggered Action Exception), or
- class 27 (Triggered Data Change Violation),

the schema name of the trigger is returned. Otherwise, the empty string is returned.

Notes

Considerations for the diagnostics area: The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

If the GET DIAGNOSTICS statement is specified in an SQL function, SQL procedure, or trigger:

- If information is desired about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error.
- If information is wanted about a warning:
 - If a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first statement specified in that handler.
 - If a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

Otherwise, GET DIAGNOSTICS statement returns information about the last executed statement.

Considerations for the SQLCODE and SQLSTATE SQL variables: The GET DIAGNOSTICS statement changes the value of the SQLSTATE and SQLCODE SQL variables.

Case of return values: Values for identifiers in returned diagnostic items are not delimited and are case sensitive. For example, a table name of "abc" would be returned, simply as abc.

Variable assignment: If an assignment error occurs, the values in the variables are unpredictable.

Data types for items: The following table shows, the SQL data type for each diagnostic item. When a diagnostic item is assigned to a variable, the variable must be compatible with the data type of the diagnostic item.

Table 103. Data Types for GET DIAGNOSTICS Items

Item Name	Data Type
Statement Information Item

SQL statement codes and strings: The following table represents the possible values for COMMAND_FUNCTION, COMMAND_FUNCTION_CODE, DYNAMIC_FUNCTION, and DYNAMIC_FUNCTION_CODE diagnostic items.

The values in the following table are assigned by the ISO and ANSI SQL Standard and may change as the standard evolves. Include `sqlscds` in the include source files in library QSYSINC should be used when referencing these values.

<i>Table 104. SQL Statement Codes and Strings</i>

VALUES INTO	VALUES INTO	-66
WHILE	WHILE	97
Unrecognized statement	a zero length string	0

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword EXCEPTION can be used as a synonym for CONDITION.
- The keyword RETURN_STATUS can be used as a synonym for DB2_RETURN_STATUS.

Example

In an SQL procedure, execute a GET DIAGNOSTICS statement to determine how many rows were updated.

```

CREATE PROCEDURE sqlprocg (IN deptnbr VARCHAR(3))
LANGUAGE SQL
BEGIN
  DECLARE SQLSTATE CHAR(5);
  DECLARE rcount INTEGER;
  UPDATE CORPDATA.PROJECT
    SET PRSTAFF = PRSTAFF + 1.5
   WHERE DEPTNO = deptnbr;
  GET DIAGNOSTICS rcount = ROW_COUNT;
  /* At this point, rcount contains the number of rows that were updated. */

```

```
END
```

Within an SQL procedure, handle the returned status value from the invocation of a stored procedure called TRYIT. TRYIT could use the RETURN statement to explicitly return a status value or a status value could be implicitly returned by the database manager. If the procedure is successful, it returns a value of zero.

```
CREATE PROCEDURE TESTIT ()
LANGUAGE SQL
A1: BEGIN
    DECLARE RETVAL INTEGER DEFAULT 0;
    ...
    CALL TRYIT
    GET DIAGNOSTICS RETVAL = RETURN_STATUS;
    IF RETVAL <> 0 THEN
        LEAVE A1;
    ELSE
        ...
    END IF;
END A1
```

In an SQL procedure, execute a GET DIAGNOSTICS statement to retrieve the message text for an error.

```
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER,
                           OUT divide_error VARCHAR(70) )
LANGUAGE SQL
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
        GET DIAGNOSTICS CONDITION 1
            divide_error = MESSAGE_TEXT;
    SET divide_result = numerator / denominator;
END;
```

GRANT (function or procedure privileges)

This form of the GRANT statement grants privileges on a function or procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

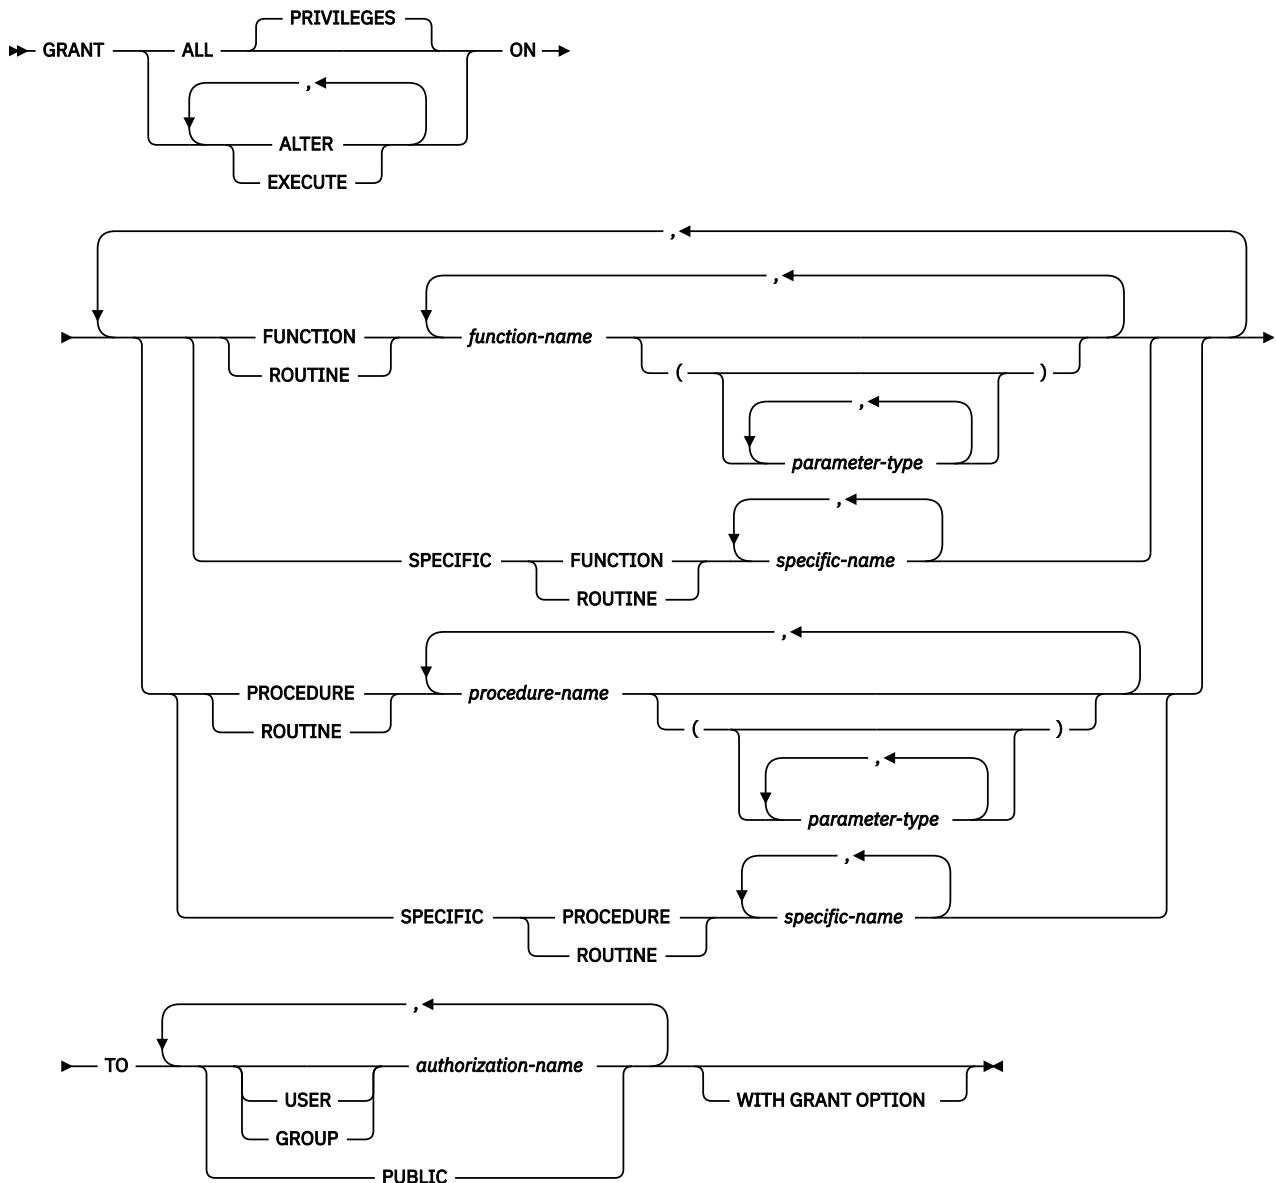

- For each function or procedure identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the function or procedure
 - The USAGE privilege on the schema (or system authority *EXECUTE on the directory if this is a Java routine) containing the function or procedure
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the function or procedure

- Database administrator authority
- Security administrator authority

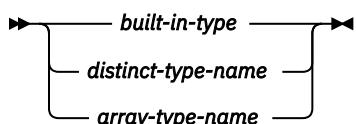

Syntax

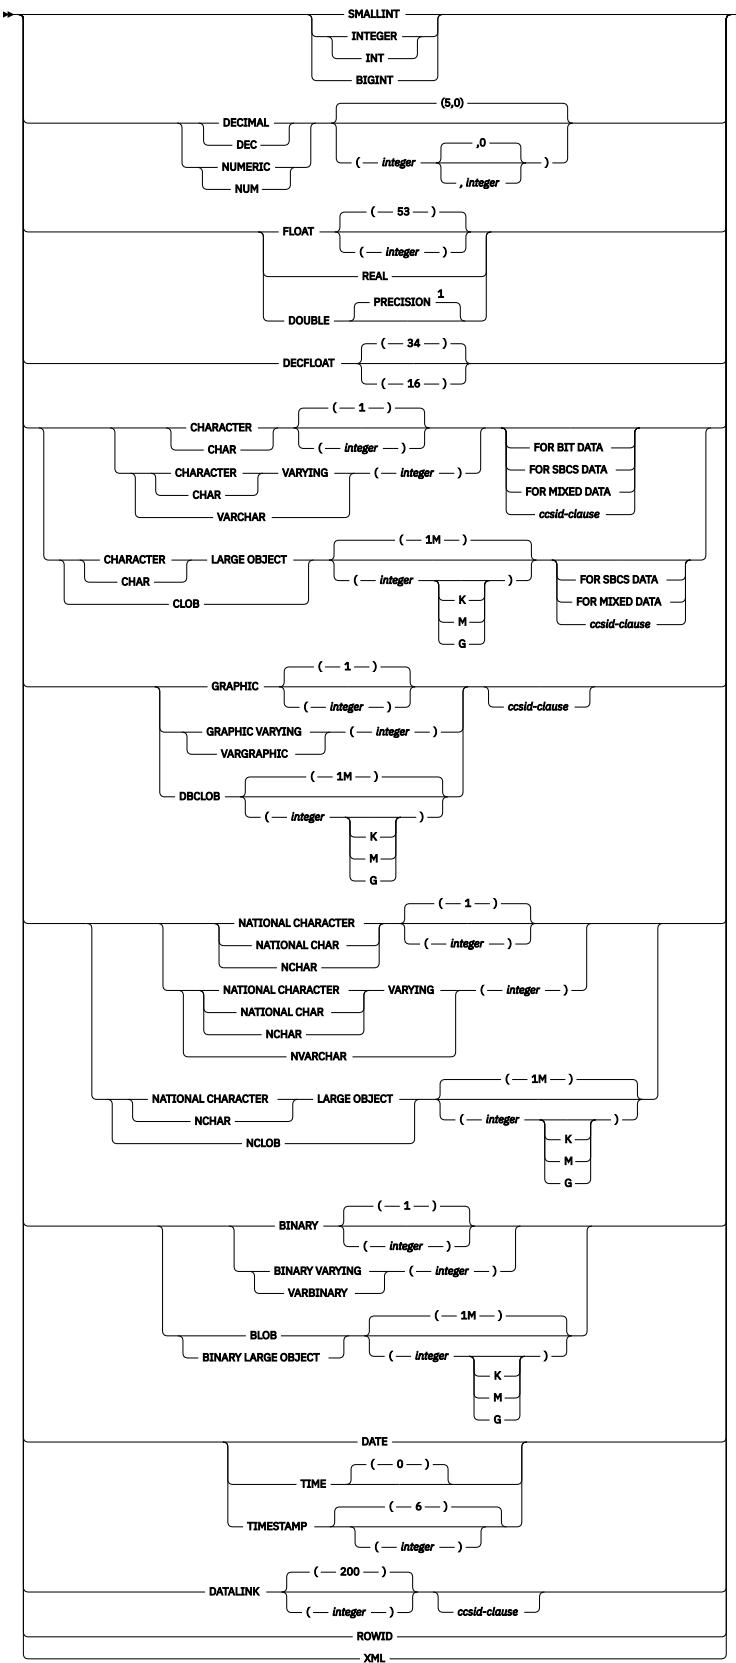

parameter-type

data-type

built-in-type

ccsid-clause

►► CCSID — *integer* ►►

Notes:

¹ The value that is specified for precision does not have to match the value that was specified when the function was created because matching is based on data type (REAL or DOUBLE).

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified functions or procedures. Note that granting ALL PRIVILEGES on a function or procedure is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the ALTER FUNCTION, ALTER PROCEDURE, or COMMENT statement.

EXECUTE

Grants the privilege to execute the function or procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the privilege is granted. The function must exist at the current server and it must be a user-defined function, but not a function that was implicitly generated with the creation of a distinct type. The function can be identified by its name, function signature, or specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type, ...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(*parameter-type, ...*)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must

exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure on which the privilege is granted. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type, ...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type, ...)* must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be granted. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name ()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the

data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the functions or procedures specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant privileges on the functions or procedures specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding System Authorities: Privileges granted to either an SQL or external function or procedure are granted to its associated program (*PGM) or service program (*SRVPGM) object. Privileges granted to a Java external function or procedure are granted to the associated class file or jar file. If the associated program, service program, class file, or jar file is not found when the grant is executed, an error is returned.

GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 105. Privileges Granted to or Revoked from Non-Java Functions or Procedures	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Function or Procedure
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *EXECUTE *OBJMGT (Revoke only)
ALTER	*OBJALTER
EXECUTE	*EXECUTE *OBJOPR

Table 105. Privileges Granted to or Revoked from Non-Java Functions or Procedures (continued)

SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Function or Procedure
WITH GRANT OPTION	*OBJMGT

Table 106. Privileges Granted to or Revoked from Java Functions or Procedures

SQL Privilege	Corresponding Data Authorities when Granting to or Revoking from a Java Function or Procedure	Corresponding Object Authorities when Granting to or Revoking from a Java Function or Procedure
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*RX	*OBJEXIST *OBJALTER *OBJREF *OBJMGT (Revoke only)
ALTER	*R	*OBJEXIST ¹¹⁰ *OBJALTER
EXECUTE	*RX	*OBJEXIST ¹¹⁰ *OBJREF
WITH GRANT OPTION	*RWX	*OBJMGT

Corresponding System Authorities When Checking Privileges to a Function or Procedure: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a function or procedure. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 107. Corresponding System Authorities When Checking Privileges to a Non-Java Function or Procedure

SQL Privilege	Corresponding System Authorities
ALTER	*OBJALTER
EXECUTE	*EXECUTE and *OBJOPR

Table 108. Corresponding System Authorities When Checking Privileges to a Java Function or Procedure

SQL Privilege	Corresponding Data Authorities when Checking Privileges to a Java Function or Procedure	Corresponding Object Authorities when Checking Privileges to a Java Function or Procedure
ALTER	*R	*OBJALTER
EXECUTE	*RX	*EXECUTE

¹¹⁰ *OBJEXIST is only revoked when the last SQL privilege that requires *OBJEXIST is revoked for the specified authorization ID or PUBLIC.

Built-in functions: Privileges cannot be granted on built-in functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.

Example

Grant the EXECUTE privilege on procedure PROCA to PUBLIC.

```
GRANT EXECUTE  
ON PROCEDURE PROCA  
TO PUBLIC
```

GRANT (package privileges)

This form of the GRANT statement grants privileges on a package.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

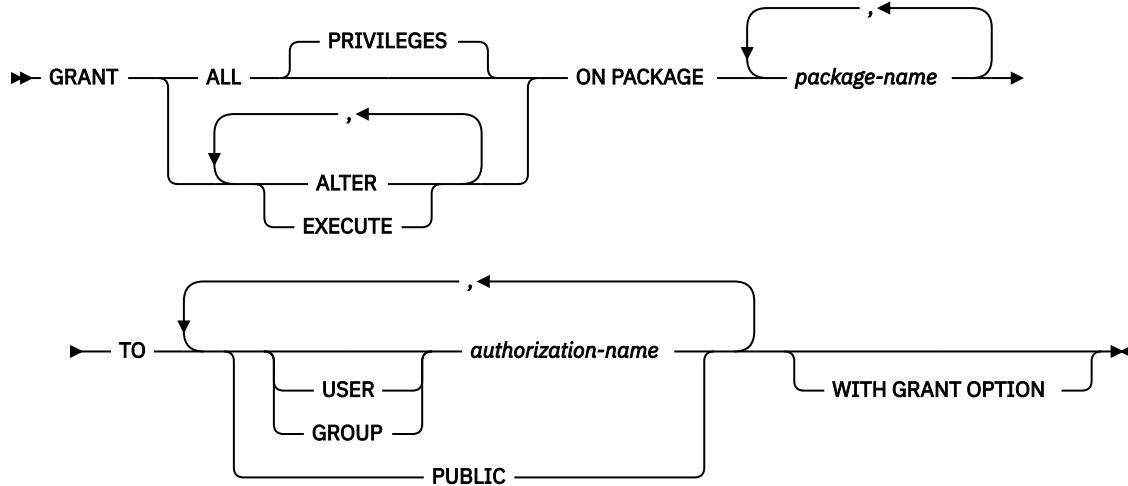

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each package identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the package
 - The USAGE privilege on the schema containing the package
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the package
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified packages. Note that granting ALL PRIVILEGES on a package is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the COMMENT and LABEL statements.

EXECUTE

Grants the privilege to execute statements in a package.

ON PACKAGE *package-name*

Identifies the packages on which you are granting the privilege. The *package-name* must identify a package that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “[Authorization, privileges and object ownership](#)” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the packages specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant privileges on the packages specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 109. Privileges Granted to or Revoked from Packages	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Package
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *EXECUTE *OBJMGT (Revoke only)
ALTER	*OBJALTER
EXECUTE	*EXECUTE *OBJOPR
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to a Package: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a package. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 110. Corresponding System Authorities When Checking Privileges to a Package	
SQL Privilege	Corresponding System Authorities When Checking Privileges to a Package
ALTER	*OBJALTER
EXECUTE	*EXECUTE and *OBJOPR

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.
- The keyword PROGRAM can be used as a synonym for PACKAGE.

Example

Grant the EXECUTE privilege on package PKGA to PUBLIC.

```
GRANT EXECUTE
  ON PACKAGE PKGA
  TO PUBLIC
```

GRANT (schema privileges)

This form of the GRANT statement grants privileges on a schema.

Invocation

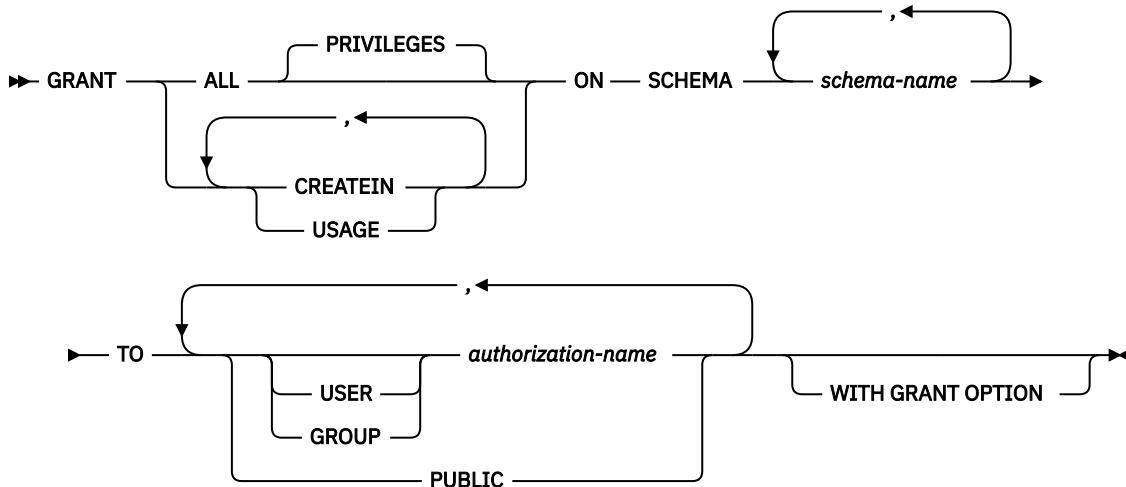

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each schema identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the schema
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified schemas. Note that granting ALL PRIVILEGES on a schema is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

CREATEIN

Grants the privilege to create objects in the schema. Other authorities or privileges required to create the object are still required.

USAGE

Grants the privilege to use the schema. USAGE privilege is required to reference any objects that exist in the schema.

ON SCHEMA *schema-name*

Identifies the schemas on which the privilege is granted.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the schemas specified in the ON clause to other users.

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges when granting to a schema. The left column lists the SQL privilege. The right column lists the equivalent system authorities that are granted or revoked.

Table 111. Privileges Granted to or Revoked from Schemas	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Schema
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJMGT (Revoke only) *OBJOPR *READ *EXECUTE *ADD
CREATEIN	*OBJOPR *READ *EXECUTE *ADD ¹¹¹
USAGE	*OBJOPR *READ *EXECUTE
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to a Schema: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a schema. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 112. Corresponding System Authorities When Checking Privileges to a Schema	
SQL Privilege	Corresponding System Authorities
CREATEIN	*OBJOPR, *READ, *EXECUTE, and *ADD ¹¹²
USAGE	*EXECUTE ¹¹²¹¹³

¹¹¹ Only *ADD is revoked when CREATEIN is revoked.

¹¹² *READ is not required on many statements, for example CREATE TABLE.

¹¹³ *OBJOPR is not required on some statements, for example ALTER TABLE.

GRANT rules: The GRANT statement will grant only those privileges that the authorization ID of the statement is allowed to grant. If no privileges were granted, an error is returned.

Example

Example 1: Grant the CREATEIN privilege on schema T_SCORES to user JONES.

```
GRANT CREATEIN  
ON SCHEMA T_SCORES  
TO JONES;
```

GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a sequence.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

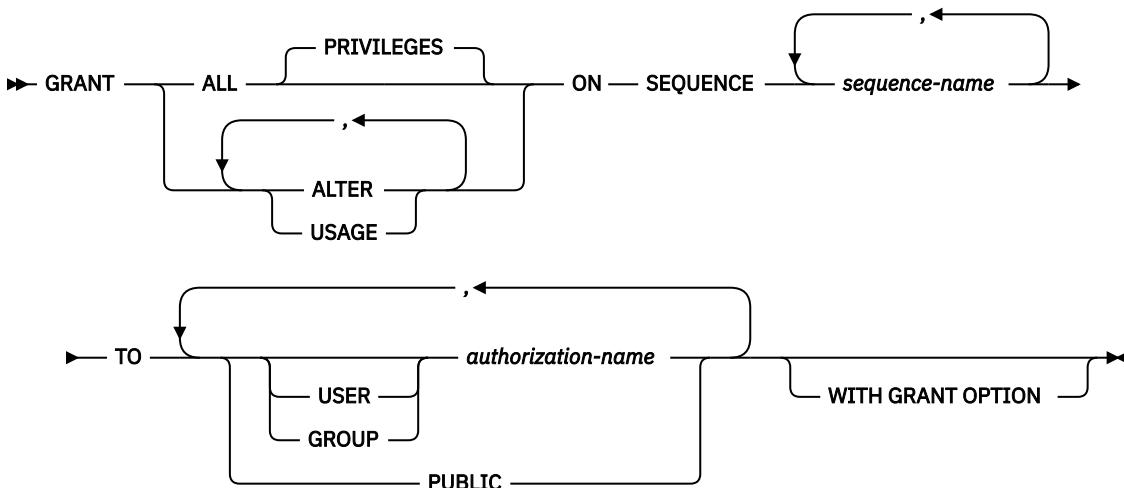

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each sequence identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the sequence
 - The USAGE privilege on the schema containing the sequence
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the sequence
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified sequences. Note that granting ALL PRIVILEGES on a sequence is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the ALTER SEQUENCE, COMMENT, and LABEL statements on a sequence.

USAGE

Grants the privilege to use the sequence in NEXT VALUE or PREVIOUS VALUE expressions.

ON SEQUENCE *sequence-name*

Identifies the sequences on which the privilege is granted. The *sequence-name* must identify a sequence that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the sequences specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant the USAGE privilege to others unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 113. Privileges Granted to or Revoked from Sequences	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Sequence
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *EXECUTE *READ *ADD *DLT *UPD *OBJMGT (Revoke only)

Table 113. Privileges Granted to or Revoked from Sequences (continued)

SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Sequence
ALTER	*OBJALTER
USAGE	*OBJOPR *EXECUTE *READ *ADD *DLT *UPD
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to a Sequence: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a sequence. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 114. Corresponding System Authorities When Checking Privileges to a Sequence

SQL Privilege	Corresponding System Authorities
ALTER	*OBJALTER
USAGE	*OBJOPR and *EXECUTE and *READ and *ADD and *DLT and *UPD

Example

Grant any user the USAGE privilege on a sequence called ORG_SEQ.

```
GRANT USAGE
  ON SEQUENCE ORG_SEQ
  TO PUBLIC
```

GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables or views.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

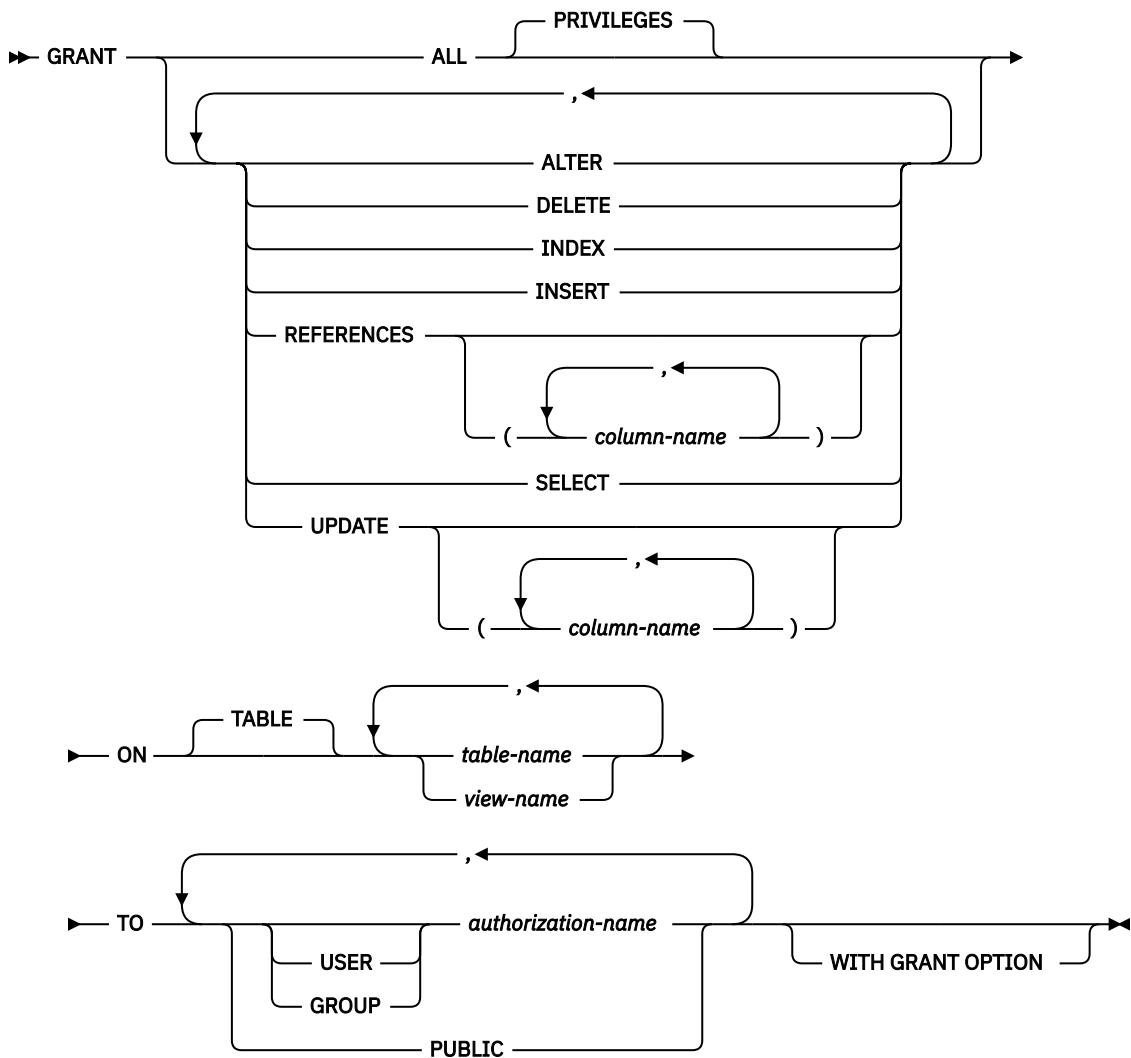

- For each table or view identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the table or view
 - The USAGE privilege on the schema containing the table or view
- For each table or view referenced directly or indirectly in the view:

- Each privilege defined in [Table 116 on page 1187](#)
- The system authority of *OBJMGT on the table or view
- The USAGE privilege on the schema containing the table or view
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the table
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified tables or views.

Note that granting ALL PRIVILEGES on a table or view is not the same as granting the system authority of *ALL.

ALTER

Grants the privilege to alter the specified table or create or drop a trigger on the specified table.

Grants the privilege to use the COMMENT and LABEL statements on tables and views.

DELETE

Grants the privilege to delete rows from the specified table or view. If a view is specified, it must be a deletable view.

INDEX

Grants the privilege to create an index on the specified table. This privilege cannot be granted on a view.

INSERT

Grants the privilege to insert rows into the specified table or view. If a view is specified, it must be an insertable view.

REFERENCES

Grants the privilege to add a referential constraint in which each specified table is a parent. If a list of columns is not specified or if REFERENCES is granted to all columns of the table or view via the specification of ALL PRIVILEGES, the grantee(s) can add referential constraints using all columns of each table specified in the ON clause as a parent key, even those added later via the ALTER TABLE statement. This privilege can be granted on a view, but the privilege is not used for a view.

REFERENCES (*column-name*,...)

Grants the privilege to add a referential constraint in which each specified table is a parent using only those columns specified in the column list as a parent key. Each *column-name* must be an unqualified name that identifies a column of each table specified in the ON clause. This privilege can be granted on the columns of a view, but the privilege is not used for a view.

SELECT

Grants the privilege to create a view or read data from the specified table or view. For example, the SELECT privilege is required if a table or view is specified in a query.

UPDATE

Grants the privilege to update rows in the specified table or view. If a list of columns is not specified or if UPDATE is granted to all columns of the table or view via the specification of ALL PRIVILEGES, the grantee(s) can update all updatable columns on each table specified in the ON clause, even those added later via the ALTER TABLE statement. If a view is specified, it must be an updatable view.

UPDATE (*column-name*,...)

Grants the privilege to use the UPDATE statement to update only those columns that are identified in the column list. Each *column-name* must be an unqualified name that identifies a column of each table and view specified in the ON clause. If a view is specified, it must be an updatable view and the specified columns must be updatable columns.

ON *table-name* or *view-name*,...

Identifies the tables or views on which the privileges are granted. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the tables and views specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant privileges on the tables and views specified in the ON clause unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding system authorities: The GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges when granting to a table. The left column lists the SQL privilege. The right column lists the equivalent system authorities that are granted or revoked.

Table 115. Privileges Granted to or Revoked from Tables	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Table
ALL (GRANT or revoke of ALL only grants or revokes those privileges the authorization ID of the statement has)	*OBJALTER ¹¹⁴ *OBJMGT (Revoke only) *OBJOPR *OBJREF *ADD *DLT *READ *UPD
ALTER	*OBJALTER ¹¹⁵
DELETE	*OBJOPR ¹¹⁶ *DLT
INDEX	*OBJALTER ¹¹⁵
INSERT	*OBJOPR ¹¹⁶ *ADD
REFERENCES	*OBJREF ¹¹⁵
SELECT	*OBJOPR ¹¹⁶ *READ
UPDATE	*OBJOPR ¹¹⁶ *UPD
WITH GRANT OPTION	*OBJMGT

¹¹⁴ The SQL INDEX and ALTER privilege correspond to the same system authority of *OBJALTER. Granting both INDEX and ALTER will not provide the user with any additional authorities.

The following table describes the system authorities that correspond to the SQL privileges when granting to a view. The left column lists the SQL privilege. The middle column lists the equivalent system authorities that are granted to or revoked from the view itself. The right column lists the system authorities that are granted to all tables and views referenced in the view's definition, and if a view is referenced, all tables and views referenced in its definition, and so on.¹¹⁷

If a view references more than one table or view, the *DLT, *ADD, and *UPD system authorities are only granted to the first table or view in the fullselect of the view definition. The *READ system authority is granted to all tables and views referenced in the view definition.

If more than one system authority will be granted with an SQL privilege, and any one of the authorities cannot be granted, then an error occurs and no authorities will be granted for that privilege. Unlike GRANT, REVOKE only revokes system authorities to the view. No system authorities are revoked from the referenced tables and views.

<i>Table 116. Privileges Granted to or Revoked from Views</i>		
SQL Privilege	Corresponding System Authorities Granted to or Revoked from View	Corresponding System Authorities Granted to Referenced Tables and Views
ALL (GRANT or REVOKE of ALL only grants or revokes those privileges the authorization ID of the statement has)	*OBJALTER *OBJMGT (Revoke only) *OBJOPR *OBJREF *ADD *DLT *READ *UPD	*ADD *DLT *READ *UPD
ALTER	*OBJALTER ¹¹⁵	None
DELETE	*OBJOPR ¹¹⁶ *DLT	*DLT
INDEX	Not Applicable	Not Applicable
INSERT	*OBJOPR ¹¹⁶ *ADD	*ADD
REFERENCES	*OBJREF ¹¹⁵	None
SELECT	*OBJOPR ¹¹⁶ *READ	*READ
UPDATE	*OBJOPR ¹¹⁶ *UPD	*UPD
WITH GRANT OPTION	*OBJMGT	None

¹¹⁵ If the WITH GRANT OPTION is given to a user, the user will also be able to perform the functions given by ALTER and REFERENCES authority.

¹¹⁶ *OBJOPR is only revoked when the last system privilege other than *OBJOPR is also revoked for the specified authorization ID or PUBLIC.

¹¹⁷ The specified rights are only granted to the tables and views referenced in the view definition if the user to whom the rights are being granted doesn't already have the rights from another authority source, for example public authority.

Corresponding system authorities when checking privileges to a table or view: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a table. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 117. Corresponding System Authorities when Checking Privileges to a Table	
SQL Privilege	Corresponding System Authorities when Checking Privileges to a Table
ALTER	*OBJALTER or *OBJMGT
DELETE	*OBJOPR and *DLT
INDEX	*OBJALTER or *OBJMGT
INSERT	*OBJOPR and *ADD
REFERENCES	*OBJREF or *OBJMGT
SELECT	*OBJOPR and *READ
UPDATE	*OBJOPR and *UPD

The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a view. The left column lists the SQL privilege. The middle column lists the equivalent system authorities that are checked on the view itself. The right column lists the system authorities that are checked on all tables and views referenced in the view's definition, and if a view is referenced, all tables and views referenced in its definition, and so on.

Table 118. Corresponding System Authorities when Checking Privileges to a View		
SQL Privilege	Corresponding System Authorities to the View	Corresponding System Authorities to the Referenced Tables and Views
ALTER	*OBJALTER and *OBJMGT	None
DELETE ¹¹⁸	*OBJOPR and *DLT	*DLT
INDEX	Not Applicable	Not Applicable
INSERT ¹¹⁹	*OBJOPR and *ADD	*ADD
REFERENCES	*OBJREF or *OBJMGT	None
SELECT	*OBJOPR and *READ	*READ
UPDATE ¹²⁰	*OBJOPR and *UPD	*UPD

¹¹⁸ When a view is created, the owner does not necessarily acquire the DELETE privilege on the view. The owner only acquires the DELETE privilege if the view allows deletes and the owner also has the DELETE privilege on the first table referenced in the subselect.

GRANT rules: The GRANT statement will grant only those privileges that the authorization ID of the statement is allowed to grant. If no privileges were granted, an error is returned.

Examples

Example 1: Grant all privileges on the table WESTERN_CR to PUBLIC.

```
GRANT ALL PRIVILEGES ON WESTERN_CR  
TO PUBLIC
```

Example 2: Grant the appropriate privileges on the CALENDAR table so that PHIL and CLAIRE can read it and insert new entries into it. Do not allow them to change or remove any existing entries.

```
GRANT SELECT, INSERT ON CALENDAR  
TO PHIL, CLAIRE
```

Example 3: Grant column privileges on TABLE1 and VIEW1 to FRED. Note that both columns specified in this GRANT statement must be found in both TABLE1 and VIEW1.

```
GRANT UPDATE(column_1, column_2)  
ON TABLE1, VIEW1  
TO FRED WITH GRANT OPTION
```

GRANT (type privileges)

This form of the GRANT statement grants privileges on a type.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the type
 - The USAGE privilege on the schema containing the type
- Database administrator authority
- Security administrator authority

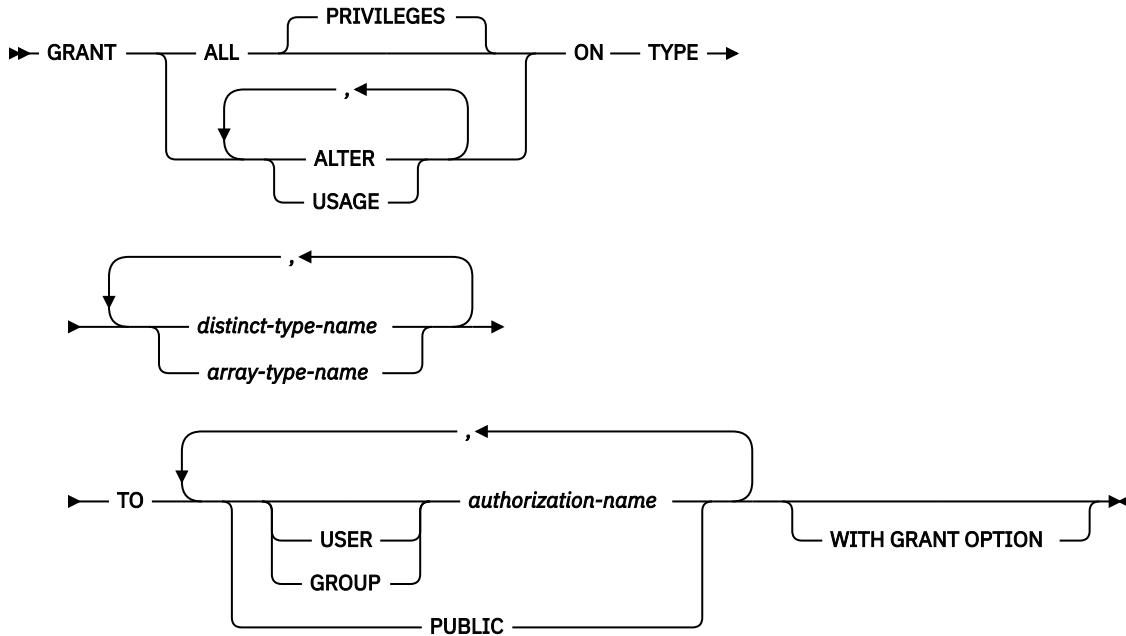

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the type
- Database administrator authority
- Security administrator authority

¹¹⁹ When a view is created, the owner does not necessarily acquire the INSERT privilege on the view. The owner only acquires the INSERT privilege if the view allows inserts and the owner also has the INSERT privilege on the first table referenced in the subselect.

¹²⁰ When a view is created, the owner does not necessarily acquire the UPDATE privilege on the view. The owner only acquires the UPDATE privilege if the view allows updates and the owner also has the UPDATE privilege on the first table referenced in the subselect.

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified distinct types or array types. Note that granting ALL PRIVILEGES on a type is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the COMMENT and LABEL statement.

USAGE

Grants the privilege to use the type in tables, functions, procedures, or CAST expressions.

ON TYPE *distinct-type-name* or *array-type-name*

Identifies the distinct types or array types on which the privilege is granted. The *distinct-type-name* or *array-type-name* must identify a user-defined type that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name...

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the types specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant the USAGE privilege to others unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 119. Privileges Granted to or Revoked from User-defined Types	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a User-defined Type
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *EXECUTE *OBJMGT (Revoke only)
ALTER	*OBJALTER
USAGE	*EXECUTE *OBJOPR
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to a User-defined Type: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a type. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 120. Corresponding System Authorities When Checking Privileges to a User-defined Type	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a User-defined Type
ALTER	*OBJALTER
USAGE	*EXECUTE and *OBJOPR

When USAGE privilege is required: USAGE privilege is required when a type is explicitly referenced in an SQL statement. For example, in a statement that contains a CAST specification or in a CREATE TABLE statement. The USAGE privilege is not required when a type is indirectly referenced. For example, when a view references a column of a table that has a distinct data type.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Example

Grant the USAGE privilege on distinct type SHOE_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE_SIZE.

```
GRANT USAGE  
ON DISTINCT TYPE SHOE_SIZE  
TO JONES
```

GRANT (variable privileges)

This form of the GRANT statement grants privileges on a global variable.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

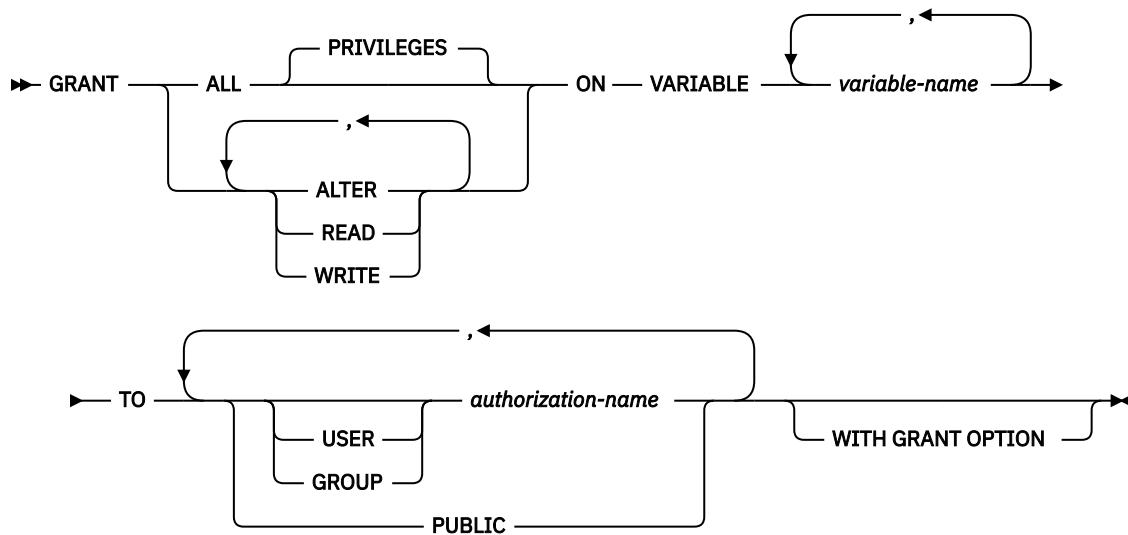

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the global variable
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the global variable
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified global variables. Note that granting ALL PRIVILEGES on a global variable is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the COMMENT and LABEL statements on a global variables.

READ

Grants the privilege to read the value of a global variable.

WRITE

Grants the privilege to assign a value to a global variable.

ON VARIABLE *variable-name*

Identifies the global variables on which the privilege is granted. The *variable-name* must identify a global variable that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the global variables specified in the ON clause to other users.

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 121. Privileges Granted to or Revoked from Global Variables	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Global Variable
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *EXECUTE *UPD *READ *OBJMGT (Revoke only)
ALTER	*OBJALTER

Table 121. Privileges Granted to or Revoked from Global Variables (continued)

SQL Privilege	Corresponding System Authorities when Granting to or Revoking from a Global Variable
READ	*OBJOPR *EXECUTE *READ
WRITE	*OBJOPR *EXECUTE *UPD
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to a Global Variable: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a global variable. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 122. Corresponding System Authorities When Checking Privileges to a Global Variable

SQL Privilege	Corresponding System Authorities
ALTER	*OBJALTER
READ	*OBJOPR and *EXECUTE and *READ
WRITE	*OBJOPR and *EXECUTE and *UPD

Example

Grant the READ and WRITE privileges on global variable MYSCHHEMA.MYJOB_PRINTER to user ZUBIRI.

```
GRANT READ, WRITE
  ON VARIABLE MYSCHHEMA.MYJOB_PRINTER
  TO ZUBIRI
```

GRANT (XML schema privileges)

This form of the GRANT statement grants privileges on an XSR object.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

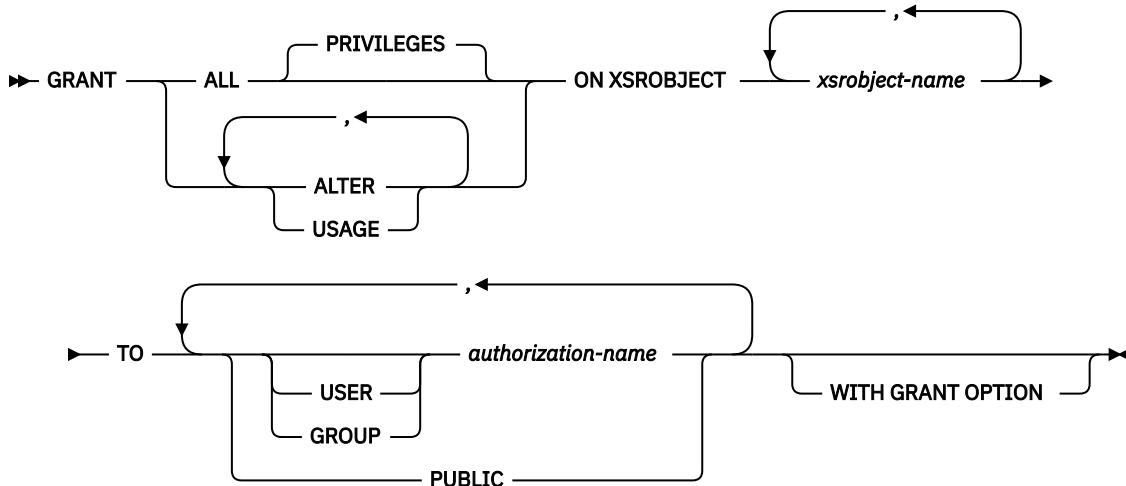

- For each XSR object identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the XSR object
 - The USAGE privilege on the schema containing the XSR object

- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the XSR object
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified XSR object. Note that granting ALL PRIVILEGES on an XSR object is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the COMMENT and LABEL statements.

USAGE

Grants the privilege to use the XSR object for validation or decomposition.

ON XSROBJECT *xsobject-name*

Identifies the XSR objects for which the privilege is granted. The *xsobject-name* must identify an XSR object that exists at the current server.

TO

Indicates to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs.

PUBLIC

Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 15.

WITH GRANT OPTION

Allows the specified *authorization-names* to grant privileges on the XSR objects specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified *authorization-names* cannot grant privileges on the XSR objects specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 123. Privileges Granted to or Revoked from XSR Objects	
SQL Privilege	Corresponding System Authorities when Granting to or Revoking from an XSR object
ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)	*OBJALTER *OBJOPR *READ *EXECUTE *OBJMGT (Revoke only)
ALTER	*OBJALTER
USAGE	*OBJOPR *EXECUTE *READ
WITH GRANT OPTION	*OBJMGT

Corresponding System Authorities When Checking Privileges to an XSR Object: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to an XSR object. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 124. Corresponding System Authorities When Checking Privileges to an XSR Object	
SQL Privilege	Corresponding System Authorities
ALTER	*OBJALTER
USAGE	*OBJOPR and *EXECUTE and *READ

Example

Grant the USAGE privilege on XSR object XMLSCHEMA to PUBLIC.

```
GRANT USAGE
  ON XSROBJECT XMLSCHEMA
  TO PUBLIC
```

HOLD LOCATOR

The HOLD LOCATOR statement allows a LOB or XML locator variable to retain its association with a value beyond a unit of work.

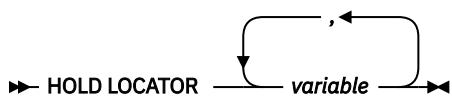

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

variable...

Identifies a variable that must be declared in accordance with the rules for declaring variable locator variables. An indicator variable must not be specified. The locator variable type must be a binary large object locator, a character large object locator, a double-byte character large object locator, or an XML locator.

After the HOLD LOCATOR statement is executed, each locator variable in the *variable* list has the hold property.

The variable must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a CALL, FETCH, SELECT INTO, SET variable, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is raised.

If more than one variable is specified in the HOLD LOCATOR statement and an error occurs on one of the locators, no locators will be held.

Note

A LOB or XML locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement without a HOLD option is executed.
- The SQL session is terminated.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the values represented by the columns. Give the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC the hold property.

```
HOLD LOCATOR :LOCRES,:LOCHIST,:LOCPIC
```

INCLUDE

The INCLUDE statement inserts application code, including declarations and statements, into a source program.

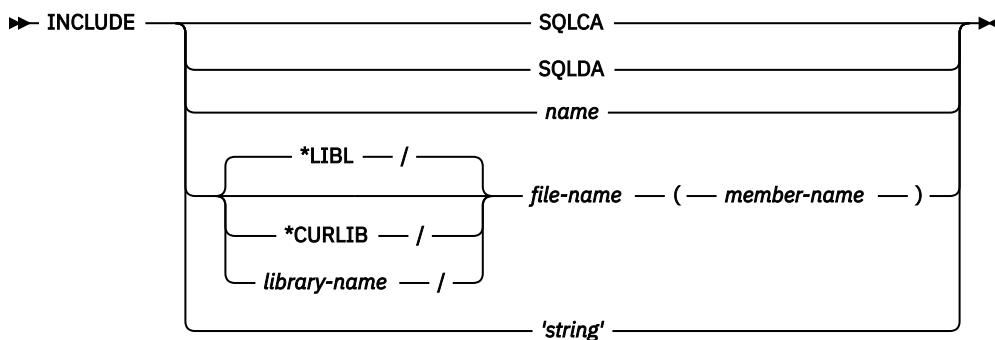

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

The authorization ID of the statement must have the system authorities *OBJOPR and *READ on the file that contains the member.

Syntax

Description

SQLCA

Indicates the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified if the program includes a stand-alone SQLCODE or a stand-alone SQLSTATE. An SQLCA can be specified for C, C++, COBOL, and PL/I. If the SQLCA is not specified, the variable SQLCODE or SQLSTATE must appear in the program.

INCLUDE SQLCA must not be specified more than once in the same program. For more information, see [“SQL diagnostic information” on page 664](#).

The SQLCA should not be specified for RPG programs. In an RPG program, the precompiler automatically includes the SQLCA.

For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#).

SQLDA

Specifies the description of an SQL descriptor area (SQLDA) is to be included. INCLUDE SQLDA can be specified in C, C++, COBOL, PL/I, and ILE RPG.

For a description of the SQLDA, see [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#).

name

Identifies a member or source stream file to be included in the source program.

If precompiling using the SRCFILE parameter, it identifies a member to be included from the file specified on the INCFILE parameter of the CRTSQLxxx command.

If precompiling using the SRCSTMF parameter, it identifies a file to be included using the path from the INCDIR parameter of the CRTSQLxxx command. No suffix will be appended to the name.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE *member-name* must not be specified in other than the DATA DIVISION or PROCEDURE DIVISION.

file-name (member-name)

Identifies a source file and member to be included in the source program. The library containing the source file is specified in one of these ways:

***LIBL**

Libraries in the job's library list are searched until the first match is found. This is the default.

***CURLIB**

The current library for the job is searched. If no library is specified as the current library for the job, QGPL is used.

library-name

Identifies the name of the library to search.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE must not be specified in other than the DATA DIVISION or PROCEDURE DIVISION.

Including a source file and member is only allowed when precompiling using the SRCFILE parameter.

'string'

Identifies a file to be included using the path from the INCDIR parameter of the CRTSQLxxx command. The string will be handled as a normal SQL string literal; the source stream file rules for escaping characters will not be followed. No suffix will be appended to the string.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement.

Including a stream file is only allowed when precompiling using the SRCSTMF parameter.

When your program is precompiled, the INCLUDE statement is replaced by source statements.

The INCLUDE statement must be specified at a point in your program where the resulting source statements are acceptable to the compiler.

Notes

CCSID considerations: If the CCSID of the file specified on the SRCFILE or SRCSTMF parameter is different from the CCSID of the source for the INCLUDE statement, the INCLUDE source is converted to the CCSID of the source file.

For information about including either SQL or C source in an SQL PL routine body, see [“INCLUDE statement” on page 1394](#).

Example

Include an SQL descriptor area in a C program.

```
EXEC SQL INCLUDE SQLDA;  
  
EXEC SQL DECLARE C1 CURSOR FOR  
  SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT  
  WHERE ADMRDEPT = 'A00';  
  
EXEC SQL OPEN C1;  
  
while (SQLCODE==0) {  
  EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;  
  /* Print results */  
}  
  
EXEC SQL CLOSE C1;
```

INSERT

The *INSERT* statement inserts rows into a table or view. Inserting a row into a view also inserts the row into the table on which the view is based if no *INSTEAD OF INSERT* trigger is defined on this view. If such a trigger is defined, the trigger will be activated instead.

There are four forms of this statement:

- The *INSERT using VALUES* form is used to insert one or more rows into the table or view using the values provided or referenced.
- The *INSERT using fullselect* form is used to insert one or more rows into the table or view using values from other tables or views.
- The *INSERT using n ROWS* form is used to insert multiple rows into the table or view using the values provided in a host-structure-array.
- The *INSERT DEFAULT VALUES* form is used to insert a single row using default values for every column.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared with the exception of the *n ROWS* form, which must be a static statement embedded in an application program. The *n ROWS* form is not allowed in a REXX procedure.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

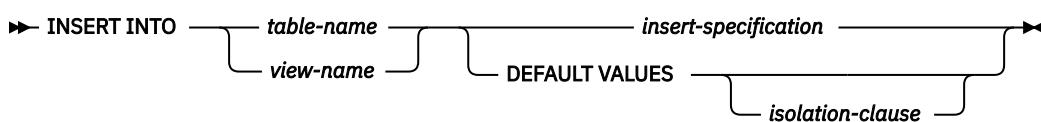

- For the table or view identified in the statement:
 - The *INSERT* privilege on the table or view, and
 - The *USAGE* privilege on the schema containing the table or view
- Database administrator authority

If a *fullselect* is specified, the privileges held by the authorization ID of the statement must also include one of the following:

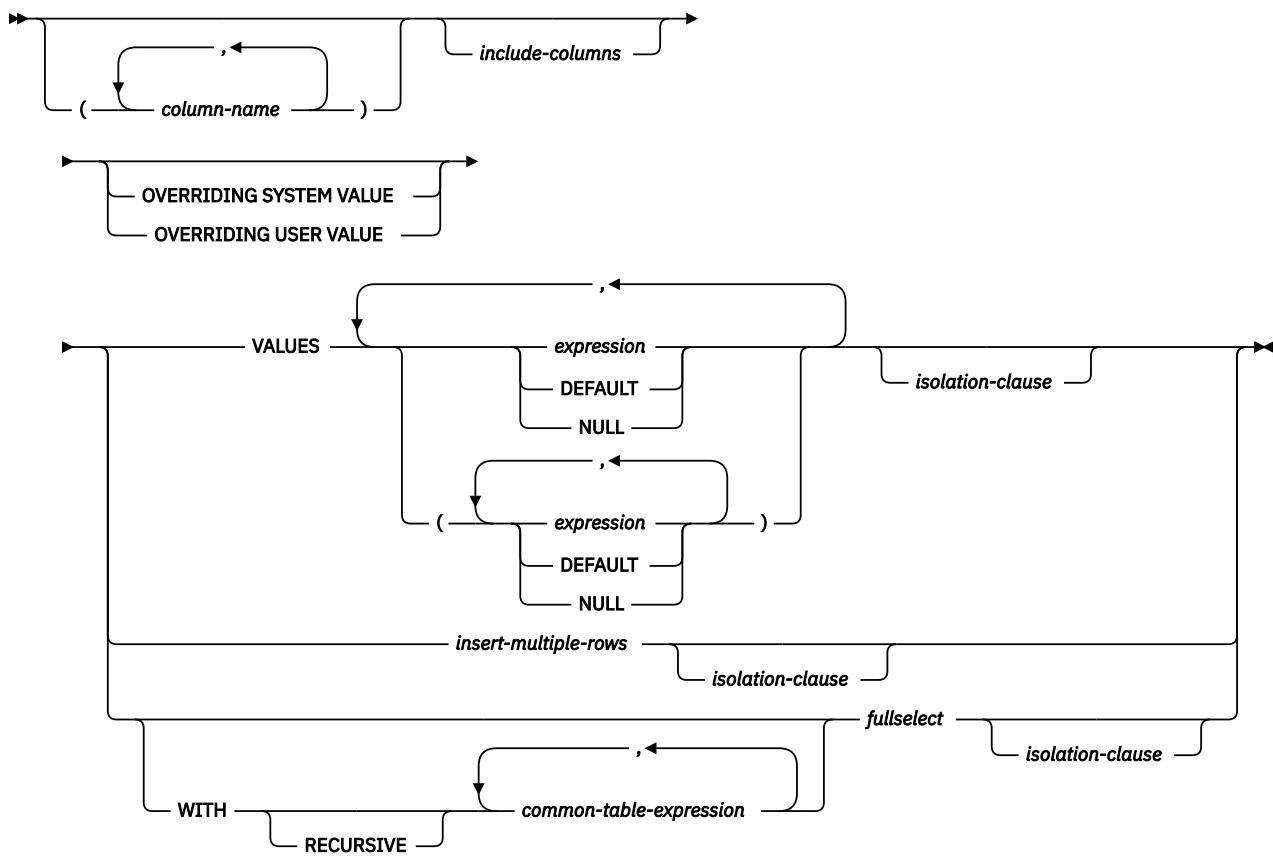

- For each table or view identified in the *fullselect*:
 - The *SELECT* privilege on the table or view, and
 - The *USAGE* privilege on the schema containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Description

INTO *table-name* or *view-name*

Identifies the object of the insert operation. The name must identify a table or view that exists at the current server, but it must not identify a history table, a catalog table, a view of a catalog table, or a view that is not insertable. For an explanation of insertable views, see “[CREATE VIEW](#)” on page 1029.

DEFAULT VALUES

Specifies that a default value will be assigned to every column in the table. This is the same as specifying a list of values for all the columns with each of the values being the keyword DEFAULT. The value that is inserted depends on how the column was defined, as described for the DEFAULT keyword.

(*column-name*,...)

Specifies the columns for which insert values are provided. Each name must be a name that identifies a column of the table or view. The same column must not be identified more than once. If extended indicators are not enabled, a view column that is not updatable must not be identified. If extended indicators are not enabled and the object of the insert operation is a view with non-updatable columns, a list of column names must be specified and the list must not identify those columns. For an explanation of updatable columns in views, see “[CREATE VIEW](#)” on page 1029.

Omission of the column list is an implicit specification of a list in which every column of the table or view is identified in left-to-right order. Any columns defined with the hidden attribute are omitted. This list is established when the statement is prepared and, therefore, does not include columns that were added to a table after the statement was prepared.

If the INSERT statement is embedded in an application and the referenced table or view exists at create program time, the statement is prepared at create program time. Otherwise, the statement is prepared at the first successful execute of the INSERT statement.

include-columns

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the intermediate result table of the INSERT statement when it is nested in the FROM clause of a fullselect. The *include-columns* are appended to the end of the list of columns specified by *table-name* or *view-name*.

INCLUDE

Specifies a list of columns to be included in the intermediate result table of the INSERT statement. This clause can only be specified if the INSERT statement is nested in the FROM clause of a fullselect.

column-name

Specifies a column of the intermediate result table of the INSERT statement. The name cannot be the same as the name of another include column or a column in *table-name* or *view-name*.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. The name must not be the same as any *column-name* or *system-column-name* in the INCLUDE column list or in *table-name* or *view-name*.

data-type

Specifies the data type of the include column. For a description of *data-type*, see “[CREATE TABLE](#)” on page 945. If a DATALINK data-type is used, FILE LINK CONTROL is not allowed.

OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE

Specifies whether system generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns for the INSERT statement must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns for the INSERT statement must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

OVERRIDING SYSTEM VALUE

Specifies that the value specified in the VALUES clause or produced by a fullselect for a ROWID, identity, or row change timestamp column that is defined as GENERATED ALWAYS is used. A system-generated value is not inserted.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

OVERRIDING USER VALUE

Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE nor OVERRIDING USER VALUE is specified:

- A value other than DEFAULT cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.
- A value can be specified for a ROWID, identity, or row change timestamp column that is defined as GENERATED BY DEFAULT. If a value is specified that value is assigned to the column. However, a value can be inserted into a ROWID column defined BY DEFAULT only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i. When a value is inserted into an identity or row change timestamp column defined BY DEFAULT, the database manager does not verify that the specified value is a unique value for the column unless the identity or row change timestamp column is the sole key in a unique constraint or unique index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

VALUES

Specifies one or more new rows to be inserted.

Each variable in the clause must identify a host structure or variable that is declared in accordance with the rules for declaring host structures and variables. In the operational form of the statement, a reference to a host structure is replaced by a reference to each of its variables. For further information about variables and structures, see [“References to host variables” on page 130](#) and [“Host structures” on page 135](#).

The number of values for each row in the VALUES clause must equal the number of names in the implicit or explicit column list and the columns identified in the INCLUDE clause. The first value is inserted in the first column in the list, the second value in the second column, and so on.

expression

An *expression* of the type described in [“Expressions” on page 147](#), that does not include a column name. If *expression* is a *variable*, the variable can identify a structure. If extended indicators are enabled and the expression is not a single variable, the extended indicator values of DEFAULT and UNASSIGNED must not be used for that expression.

DEFAULT

Specifies that the default value is assigned to a column. The value that is inserted depends on how the column was defined, as follows:

- If the column is defined as a generated column based on an expression, the column value is generated by the database manager, based on that expression.
- If the column is a ROWID, an identity column, a row change timestamp column, a row-begin column, a row-end column, or a transaction-start-ID column, the database manager will generate a new value.
- If the column is specified in the INCLUDE column list, the column value is set to null.
- If the WITH DEFAULT clause is used, the default inserted is as defined for the column (see *default-clause in column-definition* in [“CREATE TABLE” on page 945](#)).
- If the WITH DEFAULT clause or the NOT NULL clause is not used, the value inserted is NULL.

- If the NOT NULL clause is used and the WITH DEFAULT clause is not used or DEFAULT NULL is used, the DEFAULT keyword cannot be specified for that column.

DEFAULT must be specified for a ROWID or a generated column that was defined as GENERATED ALWAYS unless OVERRIDING USER VALUE is specified to indicate that any user-specified value will be ignored and a unique system-generated value will be inserted.

NULL

Specifies the value for a column is the null value. NULL should only be specified for nullable columns.

WITH *common-table-expression*

Specifies a common table expression. For an explanation of common table expression, see “[common-table-expression](#)” on page 643.

fullselect

Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLSTATE is set to '02000'.

For an explanation of *fullselect*, see “[fullselect](#)” on page 638.

When the base object of the INSERT and a base object of any subselect in the *fullselect* are the same table, the select statement is completely evaluated before any rows are inserted.

The number of columns in the result table must equal the number of names implicitly or explicitly specified in the *column-name* list. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on.

isolation-clause

Specifies the isolation level to be used for this statement.

WITH

Introduces the isolation level, which may be one of:

- *RR* Repeatable read
- *RS* Read stability
- *CS* Cursor stability
- *UR* Uncommitted read
- *NC* No commit

If *isolation-clause* is not specified the default isolation is used. See “[isolation-clause](#)” on page 650 for a description of how the default is determined.

insert-multiple-rows

integer or variable ROWS

Specifies the number of rows to be inserted. If a *variable* is specified, it must be numeric with zero scale and cannot include an indicator variable.

VALUES (host-structure-array)

Specifies a set of new rows in the form of an array of host structures. The *host-structure-array* must be declared in the program in accordance with the rules for declaring host structure arrays. A parameter marker may not be used in place of the *host-structure-array* name.

The number of variables in the host structure must equal the number of names in the implicit or explicit column list and the columns identified in the INCLUDE clause. The first host structure in the array corresponds to the first row, the second host structure in the array corresponds to the second row, and so on. In addition, the first variable in the host structure corresponds with the first column of the row, the second variable in the host structure corresponds with the second column of the row, and so on.

For an explanation of arrays of host structures see “[Host structure arrays](#)” on page 136.

insert-multiple-rows is not allowed if the current connection is to a non-remote server. *insert-multiple-rows* is not allowed in a data change reference in an RPG/400 or PL/I program.

INSERT Rules

Default Values: The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view without an INSTEAD OF INSERT trigger, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.

Assignment: Insert values are assigned to columns in accordance with the storage assignment rules described in [Chapter 2, “Language elements,” on page 43](#).

Validity: Insert operations must obey the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted unless COMMIT(*NONE) was specified.

- *Unique constraints and unique indexes:* If the identified table, or the base table of the identified view, has one or more unique indexes or unique constraints, each row inserted into the table must conform to the limitations imposed by those indexes and constraints (SQLSTATE 23505).

All uniqueness checks are effectively made at the end of the statement unless COMMIT(*NONE) was specified. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted. If COMMIT(*NONE) is specified, checking is performed as each row is inserted.

- *Check constraints:* If the identified table, or the base table of the identified view, has one or more check constraints, each check constraint must be true or unknown for each row inserted into the table (SQLSTATE 23513).

The check constraints are effectively checked at the end of the statement. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted.

- *Views and the CHECK OPTION clause:* If a view is identified, the inserted rows must conform to any applicable CHECK OPTION clause (SQLSTATE 44000). For more information, see [“CREATE VIEW” on page 1029](#).

Triggers: If the identified table or the base table of the identified view has an insert trigger, the trigger is activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If the INSERT statement is used as a *data-change-table-reference*, an AFTER INSERT trigger that attempts to modify the inserted rows will cause an error.

Referential Integrity: Each nonnull insert value of a foreign key must equal some value of the parent key of the parent table in the relationship.

The referential constraints (other than a referential constraint with a RESTRICT delete rule) are effectively checked at the end of the statement. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted and any associated triggers were activated.

If the INSERT statement is used as a *data-change-table-reference*, any referential constraint that attempts to modify the inserted rows will cause an error.

XML values: A value that is inserted into an XML column must be a well-formed XML document.

Inserting rows into a table for which row or column access control is enforced: When an INSERT statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be inserted. Typically those rules are based on the authorization ID of the statement. The following rules describe how the enabled row permissions and column masks are used during INSERT:

- When a column is referenced while deriving the values of a new row, if that column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert and an error is returned.

If the OVERRIDING USER VALUE clause is specified, the corresponding values in the new row are ignored, and the above rule for column masks is not applicable to those values.

- If the row can be inserted, and there is a BEFORE INSERT trigger for the table, the trigger is activated.

Within the trigger actions, the new values for insert can be modified in the transition variables. When the values return from the trigger, the final values for the new values are the ones for insert.

- A row to be inserted must conform to the enabled row permissions.

When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. A row that conforms to all enabled row permissions is a row that, if the row is inserted, can be retrieved back using the row access control search condition.

- If the rows can be inserted and there is an AFTER INSERT trigger for the table, the trigger is activated.

The preceding rules do not apply to the *include-columns*. The *include-columns* will accept whatever values are assigned to them, which could be either masked or unmasked values.

Masked data can be assigned to a variable used as a value for the insert operation. If an insert violation check constraint does not exist for the column, the masked data will be inserted in the column and no error will be issued.

Extended indicator usage: When extended indicators are enabled, indicator values other than positive values and 0 (zero) through -7 must not be specified. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts where they are not supported.

Extended indicators: In an INSERT statement, the extended indicator value of UNASSIGNED has the effect of setting the column to its default value. If a target column is not updatable, it can only be assigned the extended indicator value of UNASSIGNED, unless it is a generated column defined as GENERATED ALWAYS. If the target column is a generated column defined as GENERATED ALWAYS, then it must be assigned the extended indicator value of DEFAULT or UNASSIGNED.

Extended indicators and insert triggers: The activation of insert triggers is not affected by the use of extended indicators. If all columns in the implicit or explicit column list have been assigned an extended indicator value of UNASSIGNED or DEFAULT, an insert where all columns have their respective default values is attempted and, if successful, the insert trigger is activated.

Extended indicators and deferred error checks: When extended indicators are enabled, validation that would normally be done during statement preparation to recognize an insert into a non-updatable column is deferred until the statement is executed.

Notes

Insert operation errors: If an insert value violates any constraints, or if any other error occurs during the execution of an INSERT statement and COMMIT(*NONE) was not specified, all changes from this statement and any triggered SQL statements are rolled back. However, other changes in the unit of work made prior to the error are not rolled back. If COMMIT(*NONE) is specified, changes are not rolled back.

Number of rows inserted: After executing an INSERT statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) of the SQLCA) is the number of rows that the database manager inserted. The ROW_COUNT item does not include the number of rows that were inserted as a result of a trigger.

For a description of ROW_COUNT, see “[GET DIAGNOSTICS](#)” on page 1144. For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),”](#) on page 1431.

Locking: If COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) is specified, one or more exclusive locks are acquired during the execution of a successful INSERT statement. Until the locks are released by a commit or rollback operation, an inserted row can only be accessed by:

- The application process that performed the insert
- Another application process using COMMIT(*NONE) or COMMIT(*CHG) through a read-only operation

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the “[COMMIT](#)” on page 790, “[ROLLBACK](#)” on page 1281, and “[LOCK TABLE](#)” on page 1219 statements. Also, see “[Isolation level](#)” on page 23 and [Database Programming](#).

If the INSERT is used as a *data-change-table-reference* where FINAL TABLE is specified, locks are placed on inserted rows until the SELECT is complete. These locks may prevent indirect changes to the inserted rows from within the same job, such as an AFTER TRIGGER attempting to change an inserted row. These locks are acquired for all isolation levels, including COMMIT(*NONE).

A maximum of 500 000 000 rows can be inserted or changed in any single INSERT statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger.

Generated columns: A generated column that is defined as GENERATED ALWAYS should not be specified in the *column-list* unless the corresponding entry in the VALUES list is DEFAULT. The user can specify the OVERRIDING USER VALUE clause to indicate that any user-specified value will be ignored and the system-generated value at the time of the INSERT will be inserted into this column.

System-generation of GENERATED ALWAYS values can be avoided through the use of the QSYS2.REPLICATION_OVERRIDE built-in global variable. When this global variable is used, the user-provided values are inserted into all columns defined as GENERATED ALWAYS. See “[REPLICATION_OVERRIDE](#)” on page 213 for details.

Inserting into tables with row-begin, row-end, or transaction start-ID columns: When a row is inserted into a table with these generated columns (for instance, a system-period temporal table), the database manager assigns values to the following columns:

- A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted within a single SQL transaction, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.
- A row-end column is assigned the maximum value for the column (9999-12-30-00.00.00000000000000).
- A transaction start-ID column is assigned a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

Inserting into a system-period temporal table: When a row is inserted into a system-period temporal table, the database manager assigns values to columns as indicated for tables with row-begin, row-end, or transaction start-ID columns. Also, when a row is inserted, no rows are added to the history table associated with the system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target of the INSERT statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

REXX: Variables cannot be used in the INSERT statement within a REXX procedure. Instead, the INSERT must be the object of a PREPARE and EXECUTE using parameter markers.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
- The keyword ALL can be used as a synonym for RS.

Examples

Example 1: Insert a new department with the following specifications into the DEPARTMENT table:

- Department number (DEPTNO) is 'E31'
- Department name (DEPTNAME) is 'ARCHITECTURE'
- Managed by (MGRNO) a person with number '00390'
- Reports to (ADMRDEPT) department 'E01'.

```
INSERT INTO DEPARTMENT
VALUES ('E31', 'ARCHITECTURE', '00390', 'E01')
```

Example 2: Insert a new department into the DEPARTMENT table as in example 1, but do not assign a manager to the new department.

```
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT)
VALUES ('E31', 'ARCHITECTURE', 'E01')
```

Example 3: Create a table MA_EMPPROJECT with the same columns as the EMPPROJECT table. Populate MA_EMPPROJECT with the rows from the EMPPROJECT table with a project number (PROJNO) starting with the letters 'MA'.

```
CREATE TABLE MA_EMPPROJECT LIKE EMPPROJECT

INSERT INTO MA_EMPPROJECT
SELECT * FROM EMPPROJECT
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

Example 4: Use a Java program statement to add a skeleton project to the PROJECT table on the connection context 'ctx'. Obtain the project number (PROJNO), project name (PROJNAME), department number (DEPTNO), and responsible employee (RESPEMP) from host variables. Use the current date as the project start date (PRSTDATE). Assign a NULL value to the remaining columns in the table.

```
#sql [ctx] { INSERT INTO PROJECT (PROJNO, PROJNAME, DEPTNO, RESPEMP, PRSTDATE)
VALUES (:PRJNO, :PRJNM, :DPTNO, :REMP, CURRENT DATE) };
```

Example 5: Insert two new departments using one statement into the DEPARTMENT table as in example 2, but do not assign a manager to the new departments.

```
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT)
VALUES ('B11', 'PURCHASING', 'B01'),
('E41', 'DATABASE ADMINISTRATION', 'E01')
```

Example 6: In a PL/I program, use a multiple-row INSERT to add 10 rows to table DEPARTMENT. The host structure array DEPT contains the data to be inserted.

```
DCL 1 DEPT(10),
      3 DEPT CHAR(3),
      3 LASTNAME CHAR(29) VARYING,
      3 WORKDEPT CHAR(6),
      3 JOB CHAR(3);

EXEC SQL INSERT INTO DEPARTMENT 10 ROWS VALUES (:DEPT);
```

Example 7: Insert a new project into the EMPPROJECT table using the Read Uncommitted (UR, CHG) option:

```
INSERT INTO EMPPROJECT
VALUES ('000140', 'PL2100', 30)
WITH CHG
```

Example 8: Specify an INSERT statement as the *data-change-table-reference* within a SELECT statement. Define an extra include column whose values are specified in the VALUES clause, which is then used as an ordering column for the inserted rows.

```
SELECT inorder, ordernum
  FROM FINAL TABLE (INSERT INTO ORDERS (CUSTNO)
                           INCLUDE(INSERTNUM INTEGER)
                           VALUES (:cnum1, 1),
                                   (:cnum2, 2)) InsertedOrders
 ORDER BY insertnum
```

LABEL

The LABEL statement adds or replaces labels in the catalog descriptions of various database objects.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

To label a table, view, alias, column, type, package, sequence, view, or XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the table, view, alias, type, package, sequence, variable, XSR object, function or procedure identified in the statement,
 - The ALTER privilege on the table, view, alias, type, package, sequence, variable, XSR object, function or procedure, and
 - The USAGE privilege on the schema containing the table, view, alias, type, package, sequence, variable, XSR object, function or procedure
- Database administrator authority

To label a constraint or trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the subject table of the constraint or trigger in the statement:
 - The ALTER privilege on the subject table, and
 - The USAGE privilege on the schema that contains the subject table
- Database administrator authority

To label an index, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the index identified in the statement,
 - The system authority *OBJALTER on the index, and
 - The USAGE privilege on the schema containing the index.
- Database administrator authority

To label a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSFUNCS and SYSROUTINES catalog view and table:

- The UPDATE privilege on SYSROUTINES,
- The system authority *OBJOPR on SYSFUNCS, and
- The USAGE privilege on schema QSYS2
- Database administrator authority

To label a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS and SYSROUTINES catalog view and table:
 - The UPDATE privilege on SYSROUTINES,
 - The system authority *OBJOPR on SYSPROCS, and
 - The USAGE privilege on schema QSYS2
- Database administrator authority

To label a mask or permission:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority” on page 15.](#)

To label a sequence, the privileges held by the authorization ID of the statement must also include at least one of the following:

- *USE authority to the Change Data Area (CHGDTAARA) CL command
- Database administrator authority

The authorization ID of the statement has the ALTER privilege on an alias when:

- It is the owner of the alias, or
- It has been granted the system authorities of either *OBJALTER or *OBJMGT to the alias

To label a variable, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the SYSVARIABLES catalog table:
 - The UPDATE privilege on SYSVARIABLES,
 - The USAGE privilege on schema QSYS2
- Database administrator authority

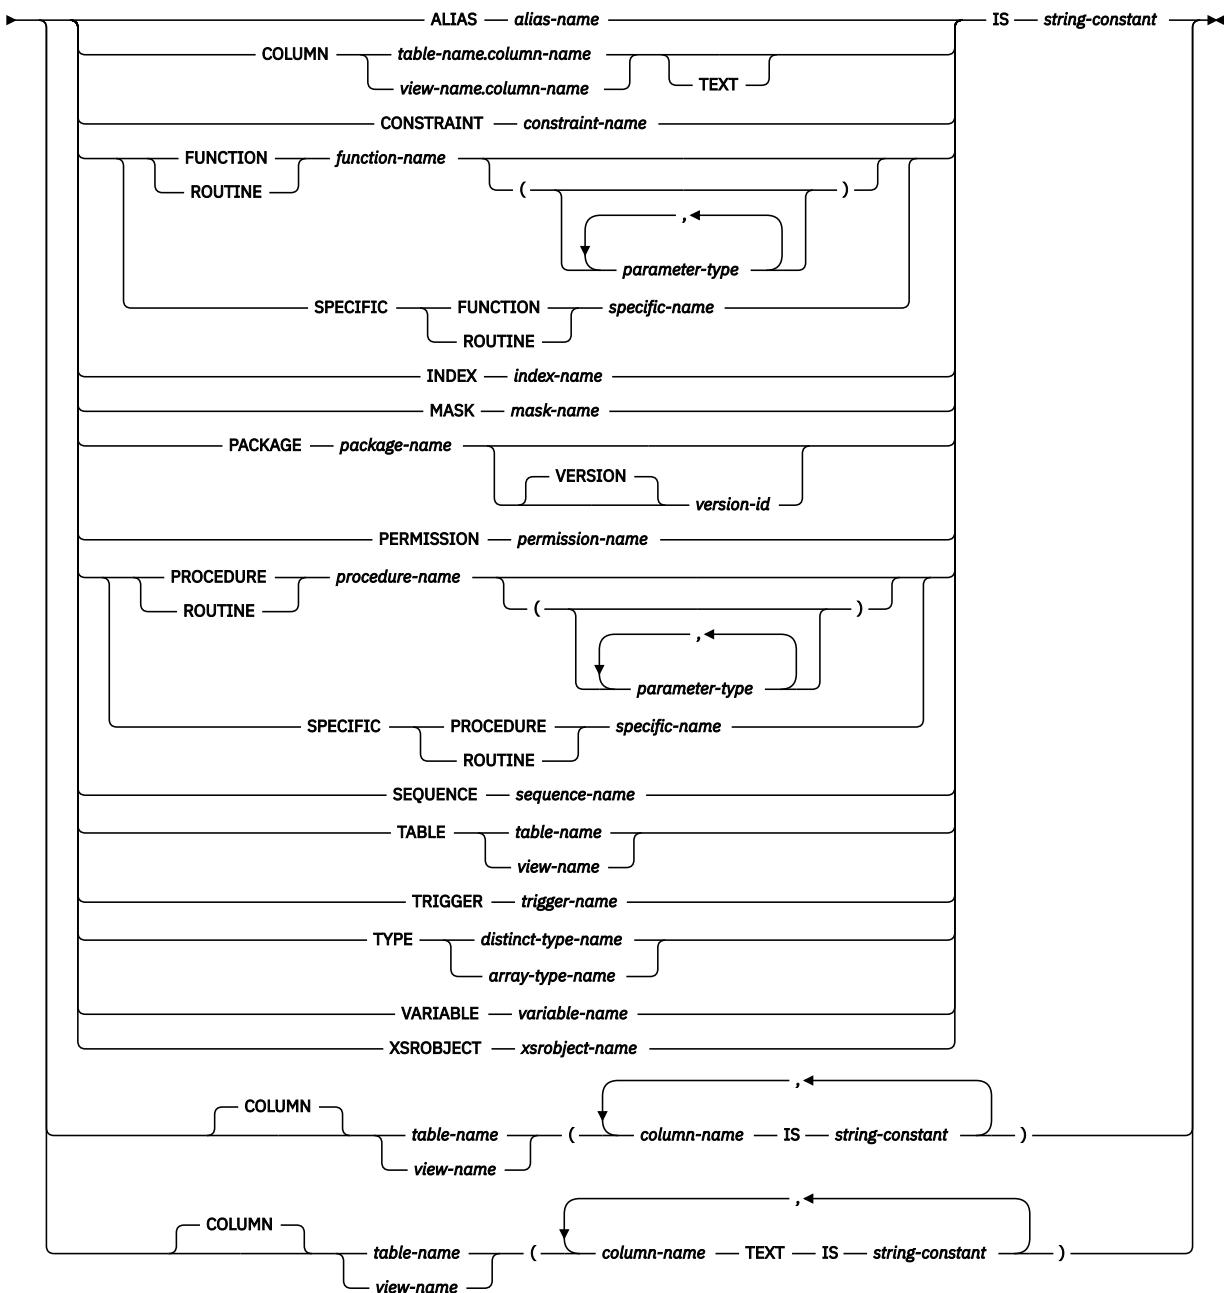

To label an XSR object, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the XSROBJECTS catalog table:
 - The UPDATE privilege on XSROBJECTS,
 - The USAGE privilege on schema QSYS2
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#), [Corresponding System Authorities When Checking Privileges to a Sequence](#), and [Corresponding System Authorities When Checking Privileges to a Package](#).

Description

ALIAS

Specifies that the label is for an alias. Labels on aliases are implemented as system object text.

alias-name

Identifies the alias to which the label applies. The name must identify an alias that exists at the current server.

COLUMN

Specifies that the label is for a column. Labels on columns are implemented as system column headings or column text. Column headings are used when displaying or printing query results.

table-name.column-name or view-name.column-name

Identifies the column to which the label applies. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table. The *column-name* must identify a column of that table or view.

TEXT

Specifies that IBM i column text is specified. If TEXT is omitted, a column heading is specified.

CONSTRAINT

Specifies that the label is for a constraint.

constraint-name

Identifies the constraint to which the label applies. The *constraint-name* must identify a constraint that exists at the current server.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the label applies. The function must exist at the current server and it must be a user-defined function. The function can be identified by its name, function signature, or specific name.

FUNCTION function-name

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION function-name (parameter-type, ...)

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which to label. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

INDEX

Specifies that the label is for an index. Labels on indexes are implemented as system object text.

index-name

Identifies the index to which the label applies. The name must identify an index that exists at the current server.

MASK

Specifies that the label is for a mask.

mask-name

Identifies the mask to which the label applies. The name must identify a mask that exists at the current server.

PACKAGE

Specifies that the label is for a package. Labels on packages are implemented as system object text.

package-name

Identifies the package to which the label applies. The name must identify a package that exists at the current server.

VERSION *version-id*

version-id is the version identifier that was assigned to the package when it was created. If *version-id* is not specified, a null string is used as the version identifier.

PERMISSION

Specifies that the label is for a permission.

permission-name

Identifies the permission to which the label applies. The name must identify a permission that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to which the label applies. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name* (*parameter-type*, ...)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name* (*parameter-type*, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be labeled on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name* () is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(*parameter-type*, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

SEQUENCE

Specifies that the label is for a sequence. Labels on sequences are implemented as system object text.

sequence-name

Identifies the sequence on which you want to add a label. The *sequence-name* must identify a sequence that exists at the current server.

TABLE

Specifies that the label is for a table or a view. Labels on tables or views are implemented as system object text.

table-name or view-name

Identifies the table or view on which you want to add a label. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TRIGGER

Specifies that the label is for a trigger.

trigger-name

Identifies the trigger on which you want to add a label. The *trigger-name* must identify a trigger that exists at the current server.

TYPE *distinct-type-name* or *array-type-name*

Identifies the distinct type or array type to which the label applies. The *distinct-type-name* or *array-type-name* must identify a type that exists at the current server.

VARIABLE *variable-name*

Identifies the variable to which the label applies. The *variable-name* must identify a variable that exists at the current server.

XSROBJECT *xsrobject-name*

Identifies the XSR object to which the label applies. The *xsrobject-name* must identify an XSR object that exists at the current server.

IS

Introduces the label you want to provide.

string-constant

Can be any SQL character-string constant of up to either 60 bytes in length for column headings or 50 bytes in length for object text or column text. The constant may contain single-byte and double-byte characters.

The label for a column heading consists of three 20-byte segments. Interactive SQL, the Query for IBM i, IBM Db2 Query Manager and SQL Development Kit for i, and other products can display or print each 20-byte segment on a separate line. If the label for a column contains mixed data, each 20-byte segment must be a valid mixed data character string. The shift characters must be paired within each 20-byte segment.

Notes

Column headings: Column headings are used when displaying or printing query results. The first column heading is displayed or printed on the first line, the second column heading is displayed or printed on the second line, and the third column heading is displayed or printed on the third line. The column headings can be up to 60 bytes in length, where the first 20 bytes is the first column heading, the second 20 bytes is the second column heading, and the third 20 bytes is the third column heading. Blanks are trimmed from the end of each 20-byte column heading.

All 60 bytes of column heading information are available in the catalog view SYSCOLUMNS; however, only the first column heading is returned in an SQLDA on a DESCRIBE or DESCRIBE TABLE statement.

Column text is not returned on a DESCRIBE or DESCRIBE TABLE statement. When the database manager changes the column heading information in a record format description that is shared, the change is reflected in all files sharing the format description. To find out if a file shares a format with another file, use the RCDFMT parameter on the CL command, Display Database Relations (DSPDBR).

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword PROGRAM can be used as a synonym for PACKAGE.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Examples

Example 1: Enter a label on the DEPTNO column of table DEPARTMENT.

**LABEL ON COLUMN DEPARTMENT.DEPTNO
IS 'DEPARTMENT NUMBER'**

Example 2: Enter a label on the DEPTNO column of table DEPARTMENT where the column heading is shown on two separate lines.

LABEL ON COLUMN DEPARTMENT.DEPTNO
IS 'Department Number'

Example 3: Enter a label on the PAYROLL package.

**LABEL ON PACKAGE PAYROLL
IS 'Payroll Package'**

LOCK TABLE

The LOCK TABLE statement either prevents concurrent application processes from changing a table or prevents concurrent application processes from using a table.

Invocation

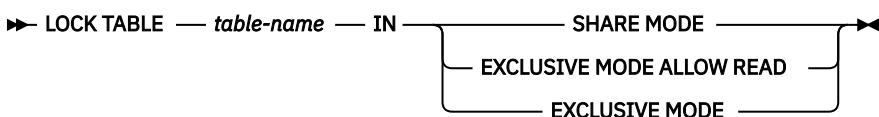

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement,
 - The system authority of *OBJOPR on the table, and
 - The USAGE privilege on the schema containing the table
 - Database administrator authority

Syntax

Description

table-name

Identifies the table to be locked. The table-name must identify a base table that exists at the current server, but must not identify a catalog table or a declared temporary table.

IN SHARE MODE

Prevents concurrent application processes from executing any but read-only operations on the table.

A shared lock (*SHRNUP) is acquired for the application process in which the statement is executed. Other application processes may also acquire a shared lock (*SHRNUP) and prevent this application process from executing any but read-only operations.

IN EXCLUSIVE MODE ALLOW READ

Prevents concurrent application processes from executing any but read-only operations on the table.

An exclusive allow read lock (*EXCLRD) is acquired for the application process in which the statement is executed. Other application processes may not acquire a shared lock (*SHRNUP) and cannot prevent this application process from executing updates, deletes, and inserts on the table.

IN EXCLUSIVE MODE

Prevents concurrent application processes from executing any operations at all on the table.

An exclusive lock (*EXCL) is acquired for the application process in which the statement is executed.

Notes

Locks obtained: Locking is used to prevent concurrent operations.

The lock is released:

- When the unit of work ends, unless the unit of work is ended by a COMMIT HOLD or ROLLBACK HOLD
- When the first SQL program in the program stack ends, unless CLOSQLCsr(*ENDJOB) or CLOSQLCsr(*ENDACTGRP) was specified on the CRTSQLxxx command
- When the activation group ends
- When the connection is changed using a CONNECT (Type 1) statement
- When the connection associated with the lock is disconnected using the DISCONNECT statement
- When the connection is in the release-pending state and a successful COMMIT occurs

You may also issue the Deallocate Object (DLCOBJ) command to unlock the table.

Lock wait time: Conflicting locks already held by other application processes will cause your application to wait up to the default wait time of the job.

Example

Obtain a lock on the DEPARTMENT table.

```
LOCK TABLE DEPARTMENT IN EXCLUSIVE MODE
```

MERGE

The MERGE statement updates a target (a table or view) using data from a source (result of a table reference). Rows in the target that match the input data may be updated or deleted as specified, and rows that do not exist in the target may be inserted as specified. Updating, deleting, or inserting a row in a view updates, deletes, or inserts the row into the tables on which the view is based if no INSTEAD OF trigger is defined on the view.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It is not allowed in a REXX procedure.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- Database administrator authority
- If an insert operation is specified:
 - The INSERT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- If a delete operation is specified:

- The DELETE privilege on the table or view, and
- The USAGE privilege on the schema containing the table or view
- If an update operation is specified:
 - The UPDATE privilege on the table or view or
 - The UPDATE privilege on each column to be updated; and
 - The USAGE privilege on the schema containing the table or view

If *search-condition*, *insert-operation*, or *assignment-clause* includes a fullselect, the privileges held by the authorization ID of the statement must also include at least one of the following:

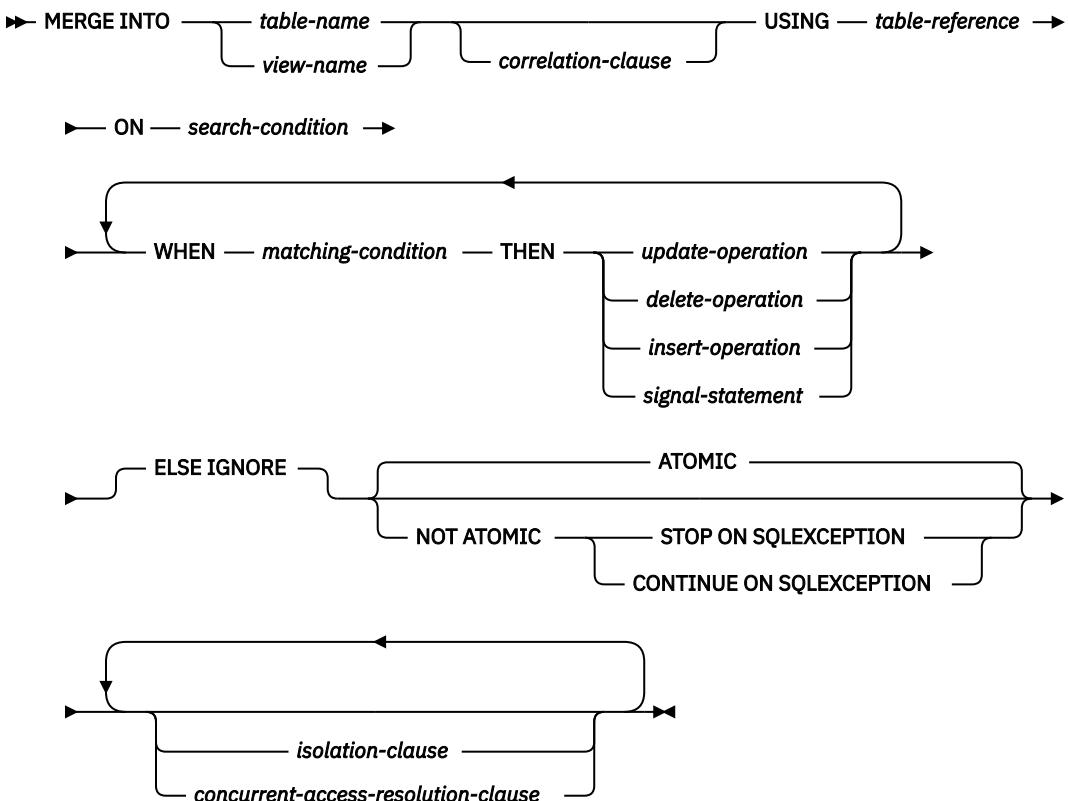

- For each table or view identified in the *fullselect*:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

If *table-reference* contains any query that references a column of a table or view, the privileges held by the authorization ID of the statement must also include at least one of the following:

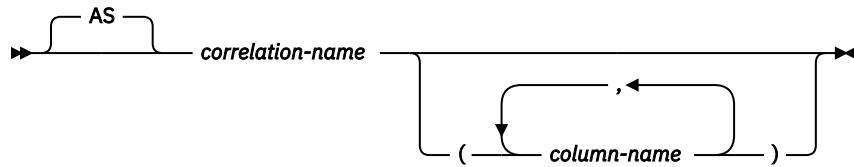

- For each table or view identified in the *fullselect*:
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

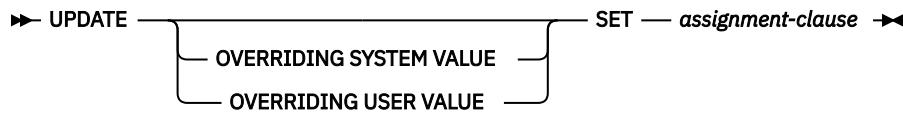

correlation-clause

matching-condition

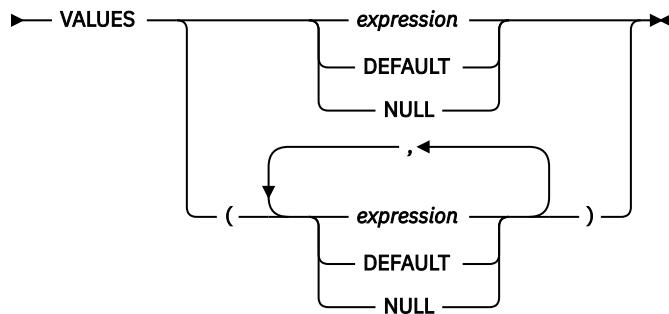

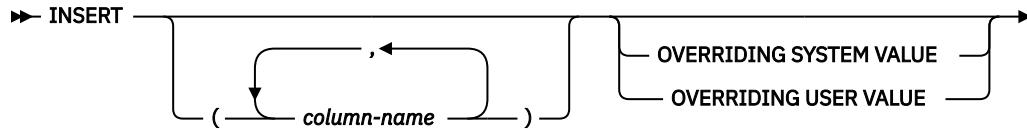

update-operation

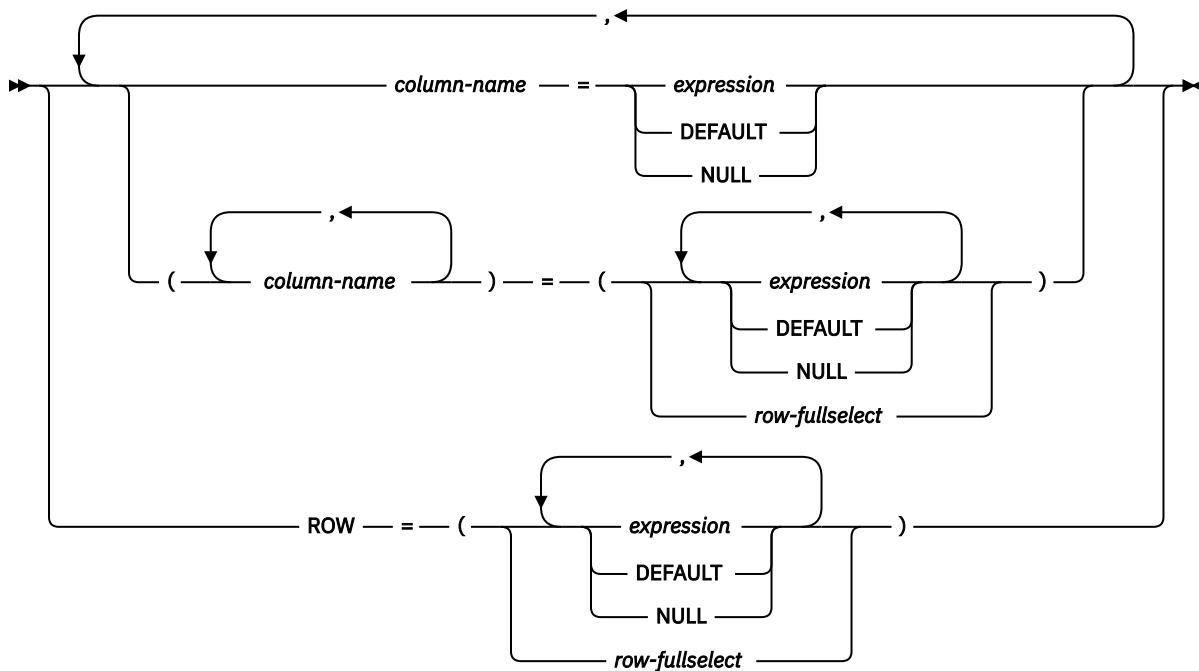

delete-operation

\blacktriangleright DELETE \blacktriangleright

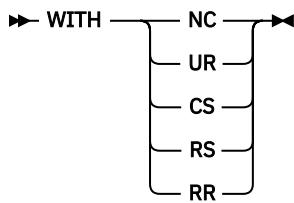

insert-operation

assignment-clause

isolation-clause

Description

table-name or view-name

Identifies the target of the update, insert, and delete operations of the merge. The name must identify a table or view that exists at the current server, but it must not identify a catalog table, a view of a catalog table, a read-only view, or a non-deletable view independent of any INSTEAD OF triggers defined for it. If *table-name* identifies a history table, no update or insert operations can be specified for the MERGE statement.

AS correlation-name

Can be used within *search-condition*, *matching-condition*, or on the right side of an *assignment-clause* to designate the target table or view. The *correlation-name* is used to qualify references to the columns of the table or view. When a *correlation-name* is specified, *column-names* can also be specified to give names to the columns of the *table-name* or *view-name*. If a column list is specified, there must be a name in the column list for each column in the table or view. For more information, see “[Correlation names](#)” on page 123

USING *table-reference*

Specifies a set of rows as a result table to be merged into the target. If the result table is empty, a warning is returned.

ON *search-condition*

Specifies the predicates used to determine whether a row from *source-table* matches rows in the target table.

Each *column-name* in the *search-condition*, other than in a subquery, must name a column of the target table or view or the *table-reference*. When the search condition includes a subquery in which the same table is the base object of both the merge and the subquery, the subquery is completely evaluated before any rows are updated or inserted.

Logically, a right join is performed between the target table and the *table-reference* using the ON *search-condition*. For those rows of the join result table where the search condition is true, the specified update or delete operation is performed. For those rows of the join result table where the search condition is not true, the specified insert operation is performed.

The search-condition cannot contain a quantified subquery, IN predicate with a subselect, or EXISTS subquery. It can contain basic predicate subqueries or scalar-fullselects. It cannot contain expressions that use aggregate functions or non-deterministic scalar functions.

WHEN matching-condition

Specifies the condition under which the *update-operation*, *delete-operation*, *insert-operation*, or the *signal-statement* is executed. Each *matching-condition* is evaluated in order of specification. Rows for which the *matching-condition* evaluates to true are not considered in subsequent matching conditions.

MATCHED

Indicates the operation to be performed on the rows where the ON *search-condition* is true. Only UPDATE, DELETE, or *signal-statement* can be specified after THEN.

AND search-condition

Specifies a further search condition to be applied against the rows that matched the ON search condition for the operation to be performed after THEN.

The *search-condition* must not include a subquery in an EXISTS or IN predicate.

NOT MATCHED

Indicates the operation to be performed on the rows where the ON *search-condition* is false or unknown. Only INSERT or *signal-statement* can be specified after THEN.

AND search-condition

Specifies a further search condition to be applied against the rows that did not match the ON search condition for the operation to be performed after THEN.

The *search-condition* must not include a subquery in an EXISTS or IN predicate.

THEN

Specifies the operation to execute when the *matching-condition* evaluates to true.

update-operation

Specifies the update operation to be executed for the rows where the *matching-condition* evaluates to true.

assignment-clause

Specifies a list of column updates.

column-name

Identifies a column to be updated. The *column-name* must identify a column of the target table or view. The *column-name* must not identify a view column derived from a scalar function, constant, or expression. A column name must not be specified more than once.

A view column derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

ROW

Identifies all the columns of the target table or view except for columns defined with the hidden attribute. If a view is specified, none of the columns of the view may be derived from a scalar function, constant, or expression.

The number of expressions, NULLs, and DEFAULTs (or the number of result columns from a row-fullselect) must match the number of columns in the row.

ROW may not be specified for a view that contains a view column derived from the same column as another column of the view, because both columns cannot be updated in the same UPDATE.

expression

Indicates the new value of the column. The expression must not include an aggregate function except when it occurs within a scalar fullselect.

The expression can contain references to columns of the target *table-name* or *view-name*. For each row that is updated, the value of a target column reference in an expression is the value of the column in the row before the row is updated.

If *expression* is a reference to a single column of the source table, the source table column value may have been specified with an extended indicator value. The effects of extended indicator values apply to the corresponding target columns of the *assignment-clause*.

When extended indicators are enabled, the extended indicator values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if *expression* is more complex than the following references:

- A single column of the source table
- A single host variable

DEFAULT

Specifies that the default value is assigned to the column. DEFAULT can be specified only for columns that have a default value. For more information about default values, see the description of the DEFAULT clause in “[CREATE TABLE](#)” on page 945.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS unless OVERRIDING USER VALUE is specified to indicate that any user-specified value will be ignored and a unique system-generated value will be used. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

NULL

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

delete-operation

Specifies the delete operation to be executed for the rows where the *matching-condition* evaluates to true.

insert-operation

Specifies the insert operation to be executed for the rows where the *matching-condition* evaluates to true.

INSERT

Introduces a list of column names and row value expressions to be used for the insert operation.

The number of values in the row value expression must equal the number of names in the implicit or explicit insert column list. The first value is inserted in the first column in the list, the second value in the second column, and so on.

(*column-name*,...)

Specifies the columns for which insert values are provided. Each name must be a name that identifies a column of the table or view. The same column must not be identified more than once. If extended indicators are not enabled, a view column that is not updatable must not be identified. If extended indicators are not enabled and the object of the insert operation is a view with non-updatable columns, a list of column names must be specified and the list must not identify those columns. For an explanation of updatable columns in views, see “[CREATE VIEW](#)” on page 1029.

Omission of the column list is an implicit specification of a list in which every column of the table or view is identified in left-to-right order. Any columns defined with the hidden attribute are omitted. This list is established when the statement is prepared and, therefore, does not include columns that were added to a table after the statement was prepared.

VALUES

Specifies a new row to be inserted.

Each variable in the clause must identify a variable that is declared in accordance with the rules for declaring variables. A host structure cannot be used. For further information about variables, see [“References to host variables” on page 130](#).

expression

An *expression* of the type described in [“Expressions” on page 147](#) that does not include a reference to a column in the target table or an aggregate function with a correlated reference to a source table column.

When extended indicators are enabled, the extended indicator values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if *expression* is more complex than the following references:

- A single column of the source table
- A single host variable
- A host variable being explicitly cast

DEFAULT

Specifies that the default value is assigned to the column. DEFAULT can be specified only for columns that have a default value. For more information about default values, see the description of the DEFAULT clause in [“CREATE TABLE” on page 945](#).

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS unless OVERRIDING USER VALUE is specified to indicate that any user-specified value will be ignored and a unique system-generated value will be used. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

NULL

Specifies the value for a column is the null value. NULL should only be specified for nullable columns.

OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE

Specifies whether system generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns for the INSERT or the SET clause of the UPDATE must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns for the INSERT or the SET clause of the UPDATE must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

OVERRIDING SYSTEM VALUE

Specifies that the value specified in the VALUES or SET clause for a column that is defined as GENERATED ALWAYS is used. A system-generated value is not used.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

OVERRIDING USER VALUE

Specifies that the value specified in the VALUES or SET clause for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is used, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE nor OVERRIDING USER VALUE is specified:

- A value cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.
- A value can be specified for a ROWID, identity, or row change timestamp column that is defined as GENERATED BY DEFAULT. If a value is specified, that value is assigned to the column. However, a value can be assigned to a ROWID column defined BY DEFAULT only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i. When a value is inserted or updated for an identity or row change timestamp column defined BY DEFAULT, the database manager does not verify that the specified value is a unique value for the column unless the identity or row change timestamp column is the sole key in a unique

constraint or unique index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

signal-statement

Specifies the SIGNAL statement that is to be executed to return an error when the *matching-condition* evaluates to true. See “[SIGNAL](#)” on page 1336.

ELSE IGNORE

Specifies that no action is to be taken when the *matching-condition* for all WHEN clauses is false for a row in the USING *table-reference*. No action is taken in this case whether or not ELSE IGNORE is specified.

ATOMIC or NOT ATOMIC

Specifies how to handle errors

ATOMIC

Specifies that if an error occurs during a *update-operation*, *delete-operation*, or *insert-operation*, the entire MERGE statement is rolled back. ATOMIC is only honored when the statement is run with an isolation level other than No Commit.

NOT ATOMIC

Specifies that if an error occurs during a *update-operation*, *delete-operation*, or *insert-operation*, only that *update-operation*, *delete-operation*, or *insert-operation* is rolled back.

STOP ON SQLEXCEPTION

Specifies that if an error occurs during a *update-operation*, *delete-operation*, or *insert-operation*, the processing of the MERGE statement stops.

CONTINUE ON SQLEXCEPTION

Specifies that if an error occurs during a *update-operation*, *delete-operation*, or *insert-operation*, the processing of the MERGE statement continues.

isolation-clause

Specifies the isolation level to be used for this statement.

WITH

Introduces the isolation level, which may be one of:

- *RR* Repeatable read
- *RS* Read stability
- *CS* Cursor stability
- *UR* Uncommitted read
- *NC* No commit

If *isolation-clause* is not specified the default isolation is used. See “[isolation-clause](#)” on page 650 for a description of how the default is determined.

concurrent-access-resolution-clause

Specifies the concurrent access resolution to use for the select statement. For more information, see “[concurrent-access-resolution-clause](#)” on page 651.

MERGE Rules

- More than one *update-operation*, *delete-operation*, *insert-operation*, or *signal-statement* can be specified in a single MERGE statement.
- Each row in the target can only be operated on once. A row in the target can only be identified as MATCHED with one row in the result table of the *table-reference*. A nested SQL operation (RI or trigger except INSTEAD OF trigger) cannot specify the target table (or a table within the same hierarchy) as a target of an UPDATE, DELETE, INSERT, or MERGE statement.

For other rules that affect the update, insert, or delete portion of the MERGE statement, see the "Rules" section of the corresponding statement description.

Extended indicator usage: When extended indicators are enabled, indicator values other than positive values and 0 (zero) through -7 must not be set. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts where they are not supported.

Extended indicators: In an update operation of the MERGE statement:

- An extended indicator value of UNASSIGNED has the effect of leaving the target column set to its current value, as if it had not been specified in the statement.
- An extended indicator value of DEFAULT must not be specified for a *row-begin*, *row-end*, *transaction-start-ID*, or generated expression column.
- An extended indicator value of UNASSIGNED must not be assigned to all of the target columns.

MERGE restriction: If the target table of the MERGE statement has triggers or is the parent in a referential integrity constraint, the *update-operation* or *insert-operation* must not contain a global variable, a function, or a subselect.

Notes

Logical order of processing: For a NOT ATOMIC MERGE statement, each source row is processed independently as if a separate MERGE statement were executed for each source row. For example, a source row that causes an update of a target row, will fire any triggers (including statement level triggers) when the update of the row is performed. Thus, if 5 rows are updated, any update triggers (including statement level update triggers) will be fired 5 times.

For an ATOMIC MERGE statement, the source rows are processed as if a set of rows is processed by each WHEN clause. Thus, if 5 rows are updated, any row level update triggers will be fired 5 times, but n statement level update triggers will be fired, where n is the number of WHEN clauses that contain an UPDATE, including any WHEN clauses that contain an UPDATE that did not process any of the source rows. For ATOMIC MERGE, the logical order of processing is:

1. Determine the set of rows to be processed from the source and target. If any of the special registers CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP are used in this statement, only one clock reading is done for the whole statement.
2. Use the ON clause to classify these rows as either MATCHED or NOT MATCHED.
3. Evaluate any *matching-condition* in the WHEN clauses.
4. Evaluate any expression in any *assignment-clause* and *insert-operation*.
5. Execute each *signal-statement*.
6. Apply each *update-operation*, *delete-operation*, or *insert-operation* to the applicable rows in the order of specification. The triggers activated by each *update-operation*, *delete-operation*, or *insert-operation* are executed. Statement level triggers are activated even if no rows satisfy the *update-operation*, *delete-operation*, or *insert-operation*. Each *update-operation*, *delete-operation*, or *insert-operation* can affect the triggers of each subsequent *update-operation*, *delete-operation*, or *insert-operation*.

Number of rows updated: After executing a MERGE statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) of the SQLCA) is the number of rows operated on by the MERGE statement, excluding rows identified by the ELSE IGNORE clause. The ROW_COUNT item and SQLERRD(3) does not include the number of rows that were operated on as a result of triggers. The value in the DB2_ROW_COUNT_SECONDARY statement information item (or SQLERRD(5) of the SQLCA) includes the number of these rows.

For a description of ROW_COUNT and DB2_ROW_COUNT_SECONDARY, see "[GET DIAGNOSTICS](#)" on page [1144](#). For a description of the SQLCA, see [Appendix C, "SQLCA \(SQL communication area\),"](#) on page [1431](#).

GET DIAGNOSTICS considerations: If a MERGE statement completes with one or more errors, the GET DIAGNOSTICS statement can be used after the MERGE statement to check which input row(s) failed. The GET DIAGNOSTICS *statement-information-item*, NUMBER, indicates the number of conditions (errors of

warnings) detected by execution of the MERGE statement. For each condition, the GET DIAGNOSTICS *condition-information-item*, DB2_ROW_NUMBER, indicates the input source row that caused an error.

Inserted row cannot also be updated: No attempt is made to update a row in the target that did not already exist before the MERGE statement was executed; that is, there are no updates of rows that were inserted by the MERGE statement.

Concurrent row changes in MERGE target: MERGE processing determines affected rows in the MERGE target before performing any *update-operations*, *delete-operations*, or *insert-operations*. Unless using a restrictive isolation level such as repeatable read, concurrent processes could insert or modify rows in the MERGE target between the time when the set of affected target rows is determined and when a specific row *update-operation*, *delete-operation*, or *insert-operation* is processed. Such concurrent activity could produce an error. For example, MERGE processing could determine that a source row does not exist in the target where a column value in the target has a unique key constraint. Before the MERGE attempts to insert a new row based on the source data, a concurrent process could insert a row with the same key value. This would cause a duplicate key error when the MERGE processing attempts to insert its row.

Locking: If COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) is specified, one or more exclusive locks are acquired during the execution of a successful MERGE statement. Until the locks are released by a commit or rollback operation, an inserted or updated row can only be accessed by:

- The application process that performed the insert or update
- Another application process using COMMIT(*NONE) or COMMIT(*CHG) through a read-only operation

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the “[COMMIT](#)” on page 790, “[ROLLBACK](#)” on page 1281, and “[LOCK TABLE](#)” on page 1219 statements. Also, see “[Isolation level](#)” on page 23 and [Database Programming](#).

A maximum of 500 000 000 rows can be acquired in any single MERGE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of row locks includes any rows inserted, updated, or deleted in the MERGE target and any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger. The number of row locks also includes source rows referenced by the USING *table-reference* is COMMIT(*ALL) is specified.

Generated columns: System-generation of GENERATED ALWAYS values can be avoided through the use of the QSYS2.REPLICATION_OVERRIDE built-in global variable. When this global variable is used, the user-provided values are used for all columns defined as GENERATED ALWAYS. See “[REPLICATION_OVERRIDE](#)” on page 213 for details.

Tables with active row and column access controls: For information about how enabled row permissions and column masks affect the update and insert operations in the MERGE statement, see the INSERT and UPDATE statement information.

NOT ATOMIC processing: When NOT ATOMIC is specified, the rows of source data are processed separately. Any reference to special registers (such as CURRENT TIMESTAMP) in the MERGE statement are evaluated as each row or source data is processed. Statement level triggers are activated as each row of source data is processed.

If an error occurs during the operation for a row of source data, the row being processed at the time of the error is not inserted, updated, or deleted. Processing of an individual row is an atomic operation. Any other changes previously made during the processing of the MERGE statement are not rolled back. If CONTINUE ON EXCEPTION is specified, execution continues with the next row to be processed.

System-period temporal tables: When a MERGE statement is processed for a system-period temporal table, the rows are affected in the same way as if the specific data change operation was invoked.

Examples

Example 1: For activities whose description has changed, update the description in the archive table. For new activities, insert into the archive table. The archive and activities tables both have activity as a primary key.

```
MERGE INTO archive ar
  USING (SELECT activity, description FROM activities) ac
  ON (ar.activity = ac.activity)
WHEN MATCHED THEN
  UPDATE SET description = ac.description
WHEN NOT MATCHED THEN
  INSERT (activity, description) VALUES(ac.activity, ac.description)
```

Example 2: Using the shipment table, merge rows into the inventory table, increasing the quantity by part count in the shipment table for rows that match; else insert the new partno into the inventory table.

```
MERGE INTO inventory AS in
  USING (SELECT partno, description, count FROM shipment
        WHERE shipment.partno IS NOT NULL) AS sh
  ON (in.partno = sh.partno)
WHEN MATCHED THEN
  UPDATE SET description = sh.description,
            quantity = in.quantity + sh.count
WHEN NOT MATCHED THEN
  INSERT (partno, description, quantity)
    VALUES (sh.partno, sh.description, sh.count)
```

Example 3: Using the transaction table, merge rows into the account table, updating the balance from the set of transactions against an account ID and inserting new accounts from the consolidated transactions where they do not already exist.

```
MERGE INTO account AS a
  USING (SELECT id, SUM(amount) sum_amount FROM transaction
        GROUP BY id) AS t
  ON a.id = t.id
WHEN MATCHED THEN
  UPDATE SET balance = a.balance + t.sum_amount
WHEN NOT MATCHED THEN
  INSERT (id, balance) VALUES (t.id, t.sum_amount)
```

Example 4: Using the transaction_log table, merge rows into the employee_file table, updating the phone and office columns with the latest transaction_log row based on the transaction time, and inserting a new employee_file row where the row does not already exist.

```
MERGE INTO employee_file AS e
  USING (SELECT empid, phone, office
        FROM (SELECT empid, phone, office,
                    ROW_NUMBER() OVER (PARTITION BY empid
                                      ORDER BY transaction_time DESC) rn
              FROM transaction_log) AS nt
        WHERE rn = 1) AS t
  ON e.empid = t.empid
WHEN MATCHED THEN
  UPDATE SET (phone, office) = (t.phone, t.office)
WHEN NOT MATCHED THEN
  INSERT (empid, phone, office)
    VALUES(t.empid, t.phone, t.office)
```

Example 5: Using dynamically supplied values for an employee row, update the master employee table if the data corresponds to an existing employee, or insert the row if the data is for a new employee. The following example is a fragment of code from a C program.

```
hv1 =
"MERGE INTO employee AS t
  USING (VALUES(CAST(? AS CHAR(6)), CAST(? AS VARCHAR(12)),
                CAST(? AS CHAR(1)), CAST(? AS VARCHAR(15)),
                CAST(? AS SMALLINT), CAST(? AS INTEGER)))
        s (empno, firstname, midinit, lastname, edlevel, salary)
  ON t.empno = s.empno
WHEN MATCHED THEN
  UPDATE SET salary = s.salary"
```

```

WHEN NOT MATCHED THEN
    INSERT (empno, firstnme, midinit, lastname, edlevel, salary)
        VALUES (s.empno, s.firstnme, s.midinit, s.lastname, s.edlevel,
                s.salary)";
EXEC SQL PREPARE s1 FROM :hv1;
EXEC SQL EXECUTE s1 USING :hv2, :hv3, :hv4, :hv5, :hv6, :hv7;

```

Example 6: Update the list of activities organized by Group A in the archive table. Delete all outdated activities and update the activities information (description and date) in the archive table if they have been changed. For new upcoming activities, insert into the archive. Signal an error if the data of the activity is not known. The date of the activities in the archive table must be specified. Each group has an activities table. For example, activities_groupA contains all activities that they organize, and the archive table contains all upcoming activities organized by different groups in a company. The archive table has (group, activity) as the primary key, and data is not nullable. All activities tables have activity as the primary key. The last_modified column in the archive is defined with CURRENT TIMESTAMP as the default value.

```

MERGE INTO archive ar
    USING (SELECT activity, description, date, last_modified
           FROM activities_groupA) ac
      ON (ar.activity = ac.activity) AND ar.group = 'A'
 WHEN MATCHED AND ac.date IS NULL THEN
     SIGNAL SQLSTATE '70001'
         SET MESSAGE_TEXT = 'Activity cannot be modified. Reason: date is not known'
 WHEN MATCHED and ac.date < CURRENT DATE THEN
     DELETE
 WHEN MATCHED AND ar.last_modified < ac.last_modified THEN
     UPDATE SET (description, date, last_modified)
                = (ac.description, ac.date, DEFAULT)
 WHEN NOT MATCHED AND ac.date IS NULL THEN
     SIGNAL SQLSTATE '70002'
         SET MESSAGE_TEXT = 'Activity cannot be inserted. Reason: date is not known'

 WHEN NOT MATCHED AND ac.date >= CURRENT DATE THEN
     INSERT (group, activity, description, date)
            VALUES ('A', ac.activity, ac.description, ac.date)
 ELSE IGNORE

```

OPEN

The OPEN statement opens a cursor so that it can be used to fetch rows from its result table.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

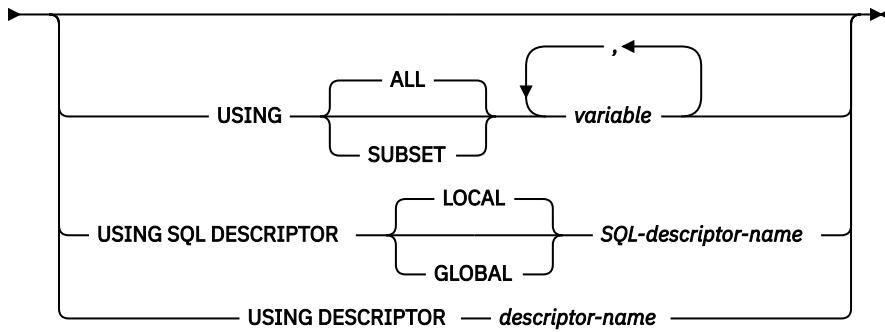

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

See [“DECLARE CURSOR” on page 1037](#) for the authorization required to use a cursor.

Syntax

► OPEN — *cursor-name* →

Description

cursor-name

Identifies the cursor to be opened. The *cursor-name* must identify a declared cursor as explained in the Notes for the DECLARE CURSOR statement. When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement associated with the cursor is either:

- The *select-statement* specified in the DECLARE CURSOR statement, or
- The prepared *select-statement* identified by the *statement-name* specified in the DECLARE CURSOR statement. If the statement has not been successfully prepared, or is not a *select-statement*, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers specified in the SELECT statement and the current values of any variables specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement and a temporary table can be created to hold them; or they can be derived during the execution of subsequent FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table. If the table is empty the position of the cursor is effectively “after the last row.”

USING

Introduces a list of variables whose values are substituted for the parameter markers (question marks) of a prepared statement. For an explanation of parameter markers, see [“PREPARE” on page 1236](#).

- If a *statement-name* is specified in the DECLARE CURSOR statement that includes parameter markers, USING must be used. If the prepared statement does not include parameter markers, USING is ignored.
- If a *select-statement* is specified in the DECLARE CURSOR statement, USING may be used to override the variable values. For more information, see [Variable value override](#).

If the DECLARE CURSOR statement names a prepared statement that includes parameter markers, you must use USING. If the prepared statement does not include parameter markers, USING is ignored.

USING ALL or USING SUBSET

Identifies host structures or variables.

USING ALL

All the variables in the list are used for substitution of parameter markers in the prepared statement.

USING SUBSET

Some or all of the variables in the list are used for substitution of parameter markers in the prepared statement.

- Any host variable with an extended indicator value of UNASSIGNED will be removed from the list. The result is as if the host variable was not specified in the statement.
- All other indicator values have no special meaning to the OPEN statement.

variable...

Identifies host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of its variables. The resulting number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter marker in the prepared statement.

A global variable may only be used if the current connection is a local connection (not a DRDA connection).

USING SQL DESCRIPTOR *SQL-descriptor-name*

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[SET DESCRIPTOR](#)” on page 1298 for an explanation of the information in the SQL descriptor.

USING DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of input variables.

Before the OPEN statement is processed, the user must set the following fields in the SQLDA. (The rules for REXX are different. For more information see [Embedded SQL Programming](#).)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the results, there must be additional SQLVAR entries for each parameter. For more information about the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see [Appendix D, “SQLDA \(SQL descriptor area\),” on page 1439](#).

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The *n*th variable described by the SQLDA corresponds to the *n*th parameter marker in the prepared statement.

Note that because RPG/400 does not provide the facility for setting pointers and the SQLDA uses pointers to locate the appropriate variables, you will have to set these pointers outside your RPG/400 application.

Notes

Closed state of cursors: All cursors in a program are in the closed state when:

- The program is called:

- If CLOSQLCsr(*ENDPGM) is specified, all cursors are in the closed state each time the program is called.
- If CLOSQLCsr(*ENDSQL) is specified, all cursors are in the closed state only the first time the program is called as long as one SQL program remains on the call stack.
- If CLOSQLCsr(*ENDJOB) is specified, all cursors are in the closed state only the first time the program is called as long as the job remains active.
- If CLOSQLCsr(*ENDMOD) is specified, all cursors are in the closed state each time the module is initiated.
- If CLOSQLCsr(*ENDACTGRP) is specified, all cursors are in the closed state only the first time the module in the program is initiated in the activation group.
- A program starts a new unit of work by executing a COMMIT statement without a HOLD option. Cursors declared with the HOLD option are not closed by a COMMIT statement without a HOLD option. A COMMIT HOLD statement does not close cursors whether they are declared with a HOLD option or not.
- A program starts a new unit of work by executing a ROLLBACK statement without a HOLD option. A ROLLBACK HOLD statement does not close cursors whether they are declared with a HOLD option or not.
- A CONNECT (Type 1) statement was executed.

A cursor can also be in the closed state because:

- A CLOSE statement was executed.
- A DISCONNECT statement disconnected the connection with which the cursor was associated.
- The connection with which the cursor was associated was in the release-pending state and a successful COMMIT occurred.
- A CONNECT (Type 1) statement was executed.

To retrieve rows from the result table of a cursor, the FETCH statement must be executed when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

Effect of temporary tables: If the result table of a cursor is not read-only, its rows are derived during the execution of subsequent FETCH statements. The same method may be used for a read-only result table. However, if a result table is read-only, Db2 for i may choose to use the temporary table method instead. With this method the entire result table is inserted into a temporary table during the execution of the OPEN statement. When a temporary table is used, the results of a program can differ in several ways:

- An error can occur during OPEN that would otherwise not occur until some later FETCH statement.
- The INSERT, UPDATE, and DELETE statements that are executed while the cursor is open cannot affect the result table.
- Any NEXT VALUE expressions in the SELECT statement are evaluated for every row of the result table during OPEN. Thus, sequence values are generated, for every row of the result table during OPEN.
- Any functions are evaluated for every row of the result table during OPEN. Thus, any external actions and SQL statements that modify SQL data within the functions are performed for every row of the result table during OPEN.

Conversely, if a temporary table is not used, INSERT, UPDATE, and DELETE statements executed while the cursor is open can affect the result table, and any NEXT VALUE expressions and functions in the SELECT statement are evaluated as each row is fetched. The effect of such operations is not always predictable. For example, if cursor CUR is positioned on a row of its result table defined as SELECT * FROM T, and a row is inserted into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A subsequent FETCH CUR might or might not retrieve the new row of T.

Parameter marker replacement: When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by its corresponding variable. The replacement of a parameter marker is an assignment operation in which the source is the value of the variable, and the target is a variable within the database manager. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the

attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see [Table 125 on page 1244](#).

Let V denote a variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column. Thus:

- V must be compatible with the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, the value of V must not be null.

However, unlike the rules for assigning a value to a column:

- If V is a string, the value will be truncated with a warning (SQLSTATE 01004), if its length is greater than the length attribute of the target.

When the SELECT statement of the cursor is evaluated, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6), and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.

Variable value override: The USING clause is intended for a prepared SELECT statement that contains parameter markers. However, it can also be used when the SELECT statement of the cursor is part of the DECLARE CURSOR statement. In this case, the OPEN statement is executed as if each variable in the SELECT statement were a parameter marker, except that the attributes of the target variables are the same as the attributes of the variables in the SELECT statement. The effect is to override the values of the variables in the SELECT statement of the cursor with the values of the variables specified in the USING clause.

Examples

Example 1: Write the embedded statements in a COBOL program that will:

1. Define a cursor C1 that is to be used to retrieve all rows from the DEPARTMENT table for departments that are administered by (ADMRDEPT) department 'A00'
2. Place the cursor C1 before the first row to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO FROM DEPARTMENT
      WHERE ADMRDEPT = 'A00' END-EXEC.

EXEC SQL OPEN C1 END-EXEC.
```

Example 2: Code an OPEN statement to associate a cursor DYN_CURSOR with a dynamically defined *select-statement* in a C program. Assume each prepared *select-statement* always defines two items in its select list with the first item having a data type of integer and the second item having a data type of VARCHAR(64). (The related host variable definitions, PREPARE statement, and DECLARE CURSOR statement are also shown in the example below.)

```
EXEC SQL BEGIN DECLARE SECTION;
  static short hv_int;
  char hv_vchar64[64];
  char stmt1_str[200];
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
EXEC SQL OPEN DYN_CURSOR USING :hv_int, :hv_vchar64;
```

Example 3: Code an OPEN statement as in example 3, but in this case the number and data types of the items in the select statement are not known.

```

EXEC SQL BEGIN DECLARE SECTION;
  char stmt1_str[200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;

EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

EXEC SQL OPEN DYN_CURSOR USING DESCRIPTOR :sqllda;

```

Example 4: Code a prepared select statement from optional pieces of text, then open it with only the host variables that apply to the generated statement.

Suppose there are three host variables with corresponding indicators:

```

PRED1HV and PRED1IND, a VARCHAR(50) variable
PRED2HV and PRED2IND, a DECIMAL(10,2) variable
PRED3HV and PRED3IND, a TIMESTAMP variable

```

Build the statement based on selection conditions set by the application. Note that this is pseudocode.

```

stmt = 'SELECT * FROM MYTABLE WHERE DUEDATE > CURRENT DATE';
IF Selection1 THEN
  stmt = stmt CONCAT ' AND COL1 = ?';
  PRED1HV = <value supplied for selection1>;
  PRED1IND = 0;
ELSE
  PRED1IND = -7; /* Predicate omitted, so omit the host variable on the OPEN */
IF Selection2 THEN
  stmt = stmt CONCAT ' AND COL2 < ?';
  PRED2HV = <value supplied for selection2>;
  PRED2IND = 0;
ELSE
  PRED2IND = -7; /* Predicate omitted, so omit the host variable on the OPEN */
IF Selection3 THEN
  stmt = stmt CONCAT ' AND COL3 = ?';
  PRED3HV = <value supplied for selection3>;
  PRED3IND = 0;
ELSE
  PRED3IND = -7; /* Predicate omitted, so omit the host variable on the OPEN */
EXEC SQL DECLARE COND_CURSOR FOR SELECT1;
EXEC SQL PREPARE SELECT1 FROM :stmt;

```

The following OPEN statement can be used for any combination of generated predicates and will omit any host variables that have an indicator value of -7. The data types of the host variables must match their use in the query, so which ones to omit is important.

```
EXEC SQL OPEN COND_CURSOR USING SUBSET :PREDHV1:PREDIND1, :PREDHV2:PREDIND2, :PREDHV3:PREDIND3;
```

If PREDIND2 has a value of -7, the OPEN is logically equivalent to:

```
EXEC SQL OPEN COND_CURSOR USING :PREDHV1:PREDIND1,:PREDHV3:PREDIND3;
```

PREPARE

The PREPARE statement creates an executable form of an SQL statement from a character-string form of the statement. The character-string form is called a *statement string*, and the executable form is called a *prepared statement*.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The authorization rules are the same as those defined for the SQL statement specified by the PREPARE statement. For example, see “[select-statement](#)” on page 642 for the authorization rules that apply when a SELECT statement is prepared.

If DLYPRP(*NO) is specified on the CRTSQLxxx command, the authorization checking is performed when the statement is prepared, except:

- If a DROP SCHEMA statement is prepared, privileges on all objects in the schema are not checked until the statement is executed.
- If a DROP TABLE statement is prepared, privileges on all views, indexes, and logical files that reference the table are not checked until the statement is executed.
- If a DROP VIEW statement is prepared, privileges on all views that reference the view are not checked until the statement is executed.
- If a CREATE TRIGGER statement is prepared, privileges on objects referenced in the *triggered-action* are not checked until the statement is executed.
- If a DROP, COMMENT, or LABEL of a FUNCTION, PROCEDURE, SEQUENCE, TYPE, TRIGGER, VARIABLE, or XSROBJECT statement is prepared, authorities are not checked until the statement is executed.
- If a GRANT or REVOKE statement is prepared, authorities are not checked until the statement is executed.

If DLYPRP(*YES) is specified on the CRTSQLxxx command, all authorization checking is deferred until the statement is executed or used in an OPEN statement.

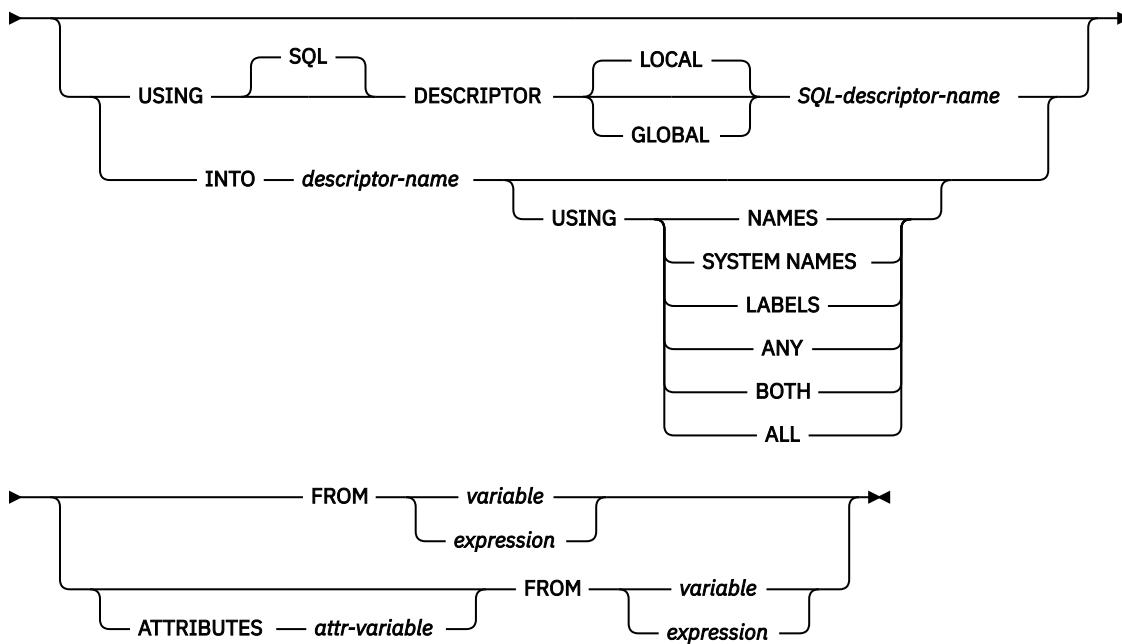

The authorization ID of the statement is the run-time authorization ID unless USRPRF(*OWNER) and DYNUSRPRF(*OWNER) were specified on the CRTSQLxxx command when the program was created. For more information, see “[Authorization IDs and authorization names](#)” on page 58.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

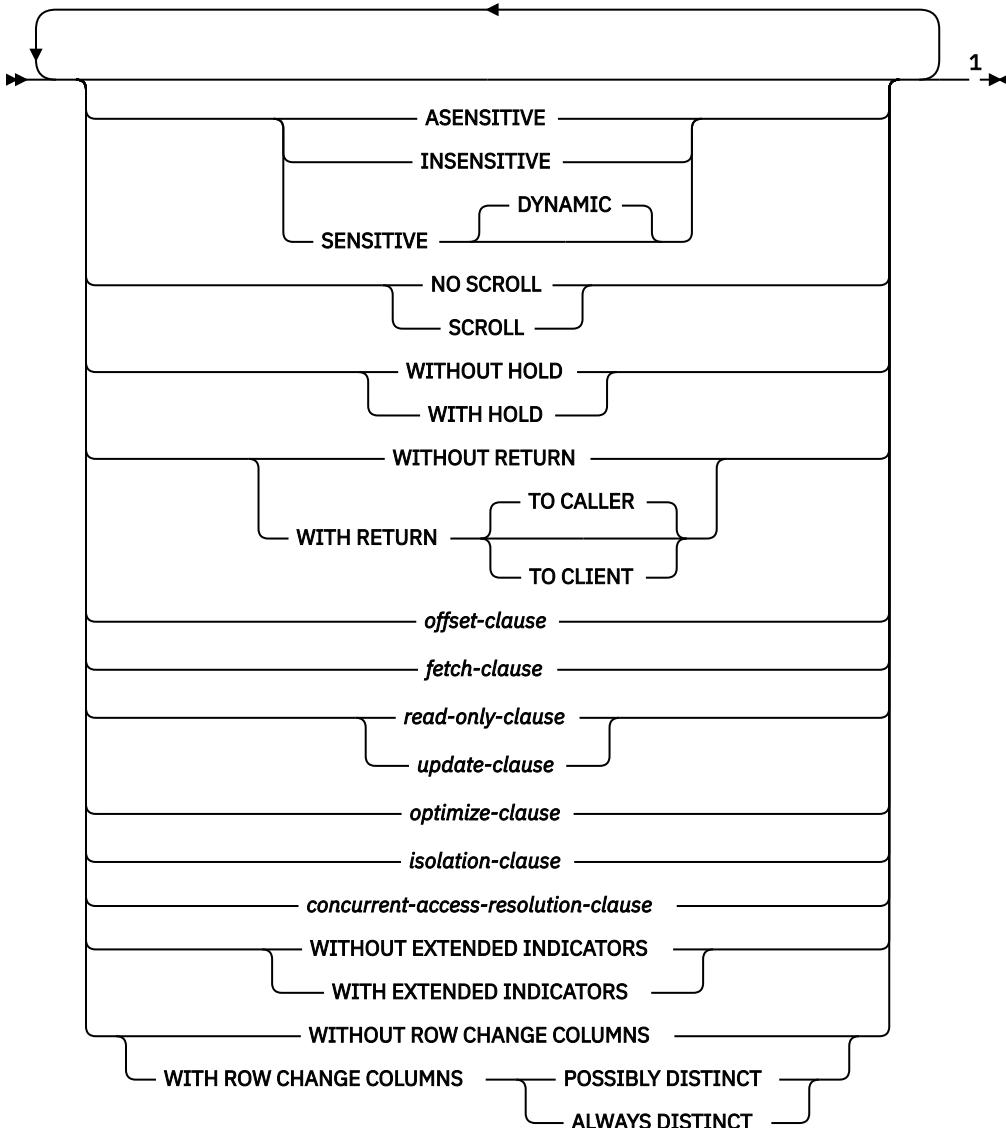

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

►► PREPARE — *statement-name* ►►

attribute-string

Notes:

- ¹ The same clause must not be specified more than once. If the options are not specified, their defaults are whatever was specified for the corresponding options in an associated DECLARE CURSOR and the prepared SELECT statement.

Description

statement-name

Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed if:

- it was prepared in the same instance of the same program, or
- CSQLCSR(*ENDJOB), CSQLCSR(*ENDACTGRP), or CSQLCSR(*ENDSQL) are specified on the CRTSQLLxx commands associated with both prepared statements.

The name must not identify a prepared statement that is the SELECT statement of an open cursor of this instance of the program.

USING SQL DESCRIPTOR *SQL-descriptor-name*

Identifies an SQL descriptor. If USING is specified, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQL descriptor specified by the *SQL-descriptor-name*. Thus, the PREPARE statement:

```
EXEC SQL PREPARE S1 USING SQL DESCRIPTOR :sqldescriptor FROM :V1;
```

is equivalent to:

```
EXEC SQL PREPARE S1 FROM :V1;  
EXEC SQL DESCRIBE S1 USING SQL DESCRIPTOR :sqldescriptor;
```

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “[GET DESCRIPTOR](#)” on page 1132 for an explanation of the information that is placed in the SQL descriptor.

INTO

If INTO is used, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the *descriptor-name*. Thus, the PREPARE statement:

```
EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;
```

is equivalent to:

```
EXEC SQL PREPARE S1 FROM :V1;  
EXEC SQL DESCRIBE S1 INTO :SQLDA;
```

descriptor-name

Identifies an SQL descriptor area (SQLDA), which is described in [Appendix D, “SQLDA \(SQL descriptor area,”](#) on page 1439. Before the PREPARE statement is executed, the following variable in the SQLDA must be set (The rules for REXX are different. For more information, see the [Embedded SQL Programming topic collection](#).) :

SQLN

Indicates the number of variables represented by SQLVAR. (SQLN provides the dimension of the SQLVAR array.) SQLN must be set to a value greater than or equal to zero before the PREPARE statement is executed. For information about techniques to determine the number of occurrences required, see “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

See “[DESCRIBE](#)” on page 1084 for an explanation of the information that is placed in the SQLDA.

USING

Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or a name is longer than 30, SQLNAME is set to length 0.

NAMES

Assigns the name of the column. This is the default. For a prepared statement where the names are explicitly specified in the select-list, the name specified is returned.

SYSTEM NAMES

Assigns the system column name of the column.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

ANY

Assigns the column label. If the column has no label, the label is the column name.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $2*n$ or $3*n$ (where n is the number of columns in the table or view). The first n occurrences of SQLVAR contain the column names. Either the second or third n occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

If the same SQLDA is used on a subsequent FETCH statement, set SQLN to n after the PREPARE is complete.

ALL

Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $3*n$ or $4*n$ (where n is the number of columns in the result table). The first n occurrences of SQLVAR contain the system column names. The second or third n occurrences contain the column labels. The third or fourth n occurrences contain the column names if they are different from the system column name. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

If the same SQLDA is used on a subsequent FETCH statement, set SQLN to n after the PREPARE is complete.

ATTRIBUTES *attr-variable*

Specifies the attributes for this cursor that are in effect if a corresponding attribute has not been specified as part of the outermost fullselect of the associated SELECT statement. If attributes are specified for the outermost fullselect, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

All attributes other than USE CURRENTLY COMMITTED and WAIT FOR OUTCOME are ignored if the prepared statement is not a *select-statement*.

attr-variable must identify a character-string or Unicode graphic variable that is declared in the program in accordance with the rules for declaring string variables. *attr-variable* must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed the maximum length of a VARCHAR. Leading and trailing blanks are removed from the value of the variable. The variable must contain a valid *attribute-string*.

An indicator variable can be used to indicate whether attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not. The options that can be specified as part of the *attribute-string* are as follows:

ASENSITIVE, SENSITIVE, or INSENSITIVE

Specifies whether the cursor is asensitive, sensitive, or insensitive to changes. For more information, see “[DECLARE CURSOR](#)” on page 1037.

If SENSITIVE is specified, then a *fetch-clause* must not be specified. If INSENSITIVE is specified, then an *update-clause* must not be specified.

NO SCROLL or SCROLL

Specifies whether the cursor is scrollable or not scrollable. For more information, see “[DECLARE CURSOR](#)” on page 1037.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation. For more information, see “[DECLARE CURSOR](#)” on page 1037.

WITHOUT RETURN or WITH RETURN

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. For more information, see “[DECLARE CURSOR](#)” on page 1037.

offset-clause

Specifies the number of rows to skip before any rows are retrieved. For more information, see “[offset-clause](#)” on page 634. The *offset-row-count* must be a constant.

fetch-clause

Specifies that a maximum number of rows should be retrieved. For more information, see “[fetch-clause](#)” on page 635. The *fetch-row-count* must be a constant. The alternate LIMIT syntax is not supported.

read-only-clause or update-clause

Specifies whether the result table is read-only or updatable. The *update-clause* clause must be specified without column names (FOR UPDATE). For more information, see “[read-only-clause](#)” on page 649 and “[update-clause](#)” on page 649.

optimize-clause

Specifies that the database manager should assume that the program does not intend to retrieve more than *integer* rows from the result table. For more information, see “[optimize-clause](#)” on page 650.

isolation-clause

Specifies an isolation level at which the select statement is executed. For more information, see “[isolation-clause](#)” on page 650.

concurrent-access-resolution-clause

Specifies the concurrent access resolution to use for the select statement. For more information, see “[concurrent-access-resolution-clause](#)” on page 651.

WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS

Specifies whether the values provided for indicator variables during execution of an INSERT or UPDATE follow standard SQL semantics for indicating NULL values, or may use extended indicator values including DEFAULT or UNASSIGNED.

WITH EXTENDED INDICATORS must only be specified when the statement is an INSERT using VALUES form of the INSERT statement, an UPDATE statement, or when the statement contains an INSERT using VALUES form of the INSERT statement.

WITHOUT ROW CHANGE COLUMNS or WITH ROW CHANGE COLUMNS POSSIBLY DISTINCT or WITH ROW CHANGE COLUMNS ALWAYS DISTINCT

Specifies whether additional column(s) should be added to the result set of a prepared *select-statement* that can be subsequently be used to identify whether a value of a column in the row might have changed. Additional row change columns are only added if a single table (or an updatable view) is referenced in the outermost subselect. The DESCRIBE and GET DESCRIPTOR statements will indicate which rows have been added.

WITHOUT ROW CHANGE COLUMNS

Row change columns are not added to the result set. This is the default.

WITH ROW CHANGE COLUMNS POSSIBLY DISTINCT

Row change columns are added to the result set even if they do not uniquely represent a single row. The columns added can be used to determine whether a value of a column in the row might have changed since it was originally fetched.

- If the row change column values have not changed since they were first fetched, then no columns of the row have been changed since they were first fetched.
- If the row change column values have changed since they were first fetched, then columns of the row may or may not have changed since the row change values are not guaranteed to represent a single row.

WITH ROW CHANGE COLUMNS ALWAYS DISTINCT

Row change columns are added to the result set only if they uniquely represent a single row. Otherwise, no row change columns are added to the result set. The columns added can be used to determine whether a value of a column in the row has changed since it was originally fetched. (Note that a table requires a row change timestamp column to guarantee that the row change columns of a row uniquely identify a single row.)

- If the row change column values have not changed since they were first fetched, then no columns of the row have been changed since they were first fetched.
- If the row change column values have changed since they were first fetched, then columns of the row have changed.

A warning is returned (SQLSTATE 0168T) if WITH ROW CHANGE COLUMNS ALWAYS DISTINCT is specified and the database manager is unable to return distinct row change columns.

FROM

Introduces the statement string. The statement string is the value of the specified *expression*, *string-expression*, or the identified *variable*.

variable

Identifies a *variable* that is declared in the program in accordance with the rules for declaring character-string or Unicode graphic variables. An indicator variable must not be specified.

expression

An *expression* of the type described in “Expressions” on page 147, that does not include an aggregate function or column name. It must return a value that is a character string or a Unicode graphic string. If a variable is specified in the *expression* it must not have a CCSID of 65535.¹²¹

The statement string must be one of the following SQL statements:

ALLOCATE CURSOR	INSERT	SET CURRENT DEGREE
ALTER	LABEL	SET CURRENT IMPLICIT XMLPARSE OPTION
ASSOCIATE LOCATORS	LOCK TABLE	SET CURRENT TEMPORAL SYSTEM_TIME
CALL	MERGE	SET ENCRYPTION PASSWORD
COMMENT	REFRESH TABLE	SET PATH
COMMIT	RELEASE SAVEPOINT	SET SCHEMA
Compound (dynamic)	RENAME	SET SESSION AUTHORIZATION
CREATE	REVOKE	SET TRANSACTION
DECLARE GLOBAL TEMPORARY TABLE	ROLLBACK	SET variable ¹²²
DELETE	SAVEPOINT	TRANSFER OWNERSHIP
DROP	<i>select-statement</i>	TRUNCATE
FREE LOCATOR	SET CURRENT DEBUG MODE	UPDATE
GRANT	SET CURRENT DECFLOAT ROUNDING MODE	VALUES INTO
HOLD LOCATOR		

The statement string must not:

- Begin with EXEC SQL.
- End with END-EXEC or a semicolon.
- Include references to variables. Global variables are allowed.

¹²¹ In a PL/I program, a PL/I string expression can also be specified.

¹²² The target of the SET variable statement must be a global variable.

Notes

Parameter markers: Although a statement string cannot include references to host variables, SQL variables, or SQL parameters, it may include *parameter markers* or global variables. Parameter markers can be replaced by the values of variables when the prepared statement is executed. A parameter marker is a question mark (?) that is used where a variable could be used if the statement string were a static SQL statement. For an explanation of how parameter markers are replaced by values, see “[OPEN](#)” on page [1231](#) and “[EXECUTE](#)” on page [1118](#).

There are two types of parameter markers:

Typed parameter marker

A parameter marker that is specified along with its target data type. It has the general form:

```
CAST(?) AS data-type
```

This notation is not a function call, but a “promise” that the type of the parameter at run time will be of the data type specified or some data type that can be converted to the specified data type. For example, in:

```
UPDATE EMPLOYEE  
  SET LASTNAME = TRANSLATE(CAST(?) AS VARCHAR(12))  
 WHERE EMPNO = ?
```

the value of the argument of the TRANSLATE function will be provided at run time. The data type of that value will either be VARCHAR(12), or some type that can be converted to VARCHAR(12). For more information, refer to “[CAST specification](#)” on page [164](#).

Untyped parameter marker

A parameter marker that is specified without its target data type. It has the form of a single question mark. The data type of an untyped parameter marker is provided by context. For example, the untyped parameter marker in the predicate of the above update statement is the same as the data type of the EMPNO column.

Typed parameter markers can be used in dynamic SQL statements wherever a variable is supported and the data type is based on the promise made in the CAST function.

Untyped parameters markers can be used in dynamic SQL statements in selected locations where variables are supported. These locations and the resulting data type are found in the following tables:

Table 125. Untyped Parameter Marker Usage in Expressions (Including Select List, CASE, and VALUES)

Untyped Parameter Marker Location	Data Type
Alone in a select list that is not in a subquery	Error
Alone in a select list that is in an EXISTS subquery	Error
Alone in a select list that is in a subquery	The data type of the other operand of the subquery. ¹²³
Alone as <i>offset-row-count</i> in an <i>offset-clause</i> .	BIGINT
Alone as <i>fetch-row-count</i> in a <i>fetch-clause</i> .	BIGINT
Both operands of a single arithmetic operator, after considering operator precedence and order of operation rules.	DECFLOAT(34)

Includes cases such as:

```
? + ? + 10
```

Table 125. Untyped Parameter Marker Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Parameter Marker Location	Data Type
One operand of a single operator in an arithmetic expression (not a datetime expression) Includes cases such as: ? + ? * 10	The data type of the other operand.
Labeled duration within a datetime expression with a unit type other than SECONDS. (Note that the portion of a labeled duration that indicates the type of units cannot be a parameter marker.)	DECIMAL(15,0)
Labeled duration within a datetime expression with a type unit of SECONDS. (Note that the portion of a labeled duration that indicates the type of units cannot be a parameter marker.)	DECIMAL(27,12)
Any other operand of a datetime expression (for instance 'timecol + ?' or '? - datecol').	Error
Both operands of a CONCAT operator	DBCLOB(1G) CCSID 1200
One operand of a CONCAT operator when the other operand is a non-CLOB character data type	VARCHAR(32740) with the same CCSID as the other operand
One operand of a CONCAT operator, when the other operand is a non-DBCLOB graphic data type	VARGRAPHIC(16370) with the same CCSID as the other operand
One operand of a CONCAT operator when the other operand is a non-BLOB binary type	VARBINARY(32740)
One operand of a CONCAT operator, when the other operand is a large object string	Same as that of the other operand
The expression following the CASE keyword in a simple CASE expression	Result of applying the “Rules for result data types” on page 99 to the expressions following the WHEN keyword that are other than untyped parameter markers
At least one of the result-expressions in a CASE expression (both Simple and Searched) with the rest of the result-expressions either untyped parameter marker or NULL.	Error
Any or all expressions following WHEN in a simple CASE expression.	Result of applying the “Rules for result data types” on page 99 to the expression following CASE and the expressions following WHEN that are not untyped parameter markers.
A result-expression in a CASE expression (both simple and searched) where at least one result-expression is not NULL and not an untyped parameter marker.	Result of applying the “Rules for result data types” on page 99 to all result-expressions that are other than NULL or untyped parameter markers.
Alone as a <i>column-expression</i> in a single-row VALUES clause that is not within an INSERT statement and not within the VALUES clause of an insert operation of a MERGE statement.	Error

Table 125. Untyped Parameter Marker Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Parameter Marker Location	Data Type
Alone as a <i>column-expression</i> in a multi-row VALUES clause that is not within an INSERT statement, and for which the <i>column-expressions</i> in the same position in all other <i>row-expressions</i> are untyped parameter markers.	Error
Alone as a <i>column-expression</i> in a multi-row VALUES clause that is not within an INSERT statement, and for which a <i>column-expression</i> in the same position of at least one other <i>row-expression</i> is not an untyped parameter marker or NULL.	Result of applying the “Rules for result data types” on page 99 to all operands that are other than untyped parameter markers.
Alone as a <i>column-expression</i> in a single-row VALUES clause within an INSERT statement.	The data type of the column. If the column is defined as a user-defined distinct type, then it is the source data type of the user-defined distinct type. ¹²³
Alone as a <i>column-expression</i> in a multi-row VALUES clause within an INSERT statement.	The data type of the column. If the column is defined as a user-defined distinct type, then it is the source data type of the user-defined distinct type. ¹²³
Alone as a <i>column-expression</i> in a VALUES clause of the source-table for a MERGE statement	Error
Alone as a <i>column-expression</i> in the VALUES clause of an insert operation of a MERGE statement	The data type of the column. If the column is defined as a user-defined distinct type, then it is the source data type of the user-defined distinct type. ¹²³
Alone as a <i>column-expression</i> on the right side of assignment-clause for an update operation of a MERGE statement	The data type of the column. If the column is defined as a user-defined distinct type, then it is the source data type of the user-defined distinct type. ¹²³
Alone as a value on the right hand side of a SET clause of an UPDATE statement.	The data type of the column. If the column is defined as a user-defined distinct type, then it is the source data type of the user-defined distinct type. ¹²³
As a value in an <i>insert-multiple-rows</i> of an INSERT statement.	INTEGER
As a value on the right side of a SET special register statement	The data type of the special register.
As a value in the VALUES clause of the VALUES INTO statement, where the associated expression is a global variable.	The data type of the global variable.
As a value in the INTO clause of the VALUES INTO statement	The data type of the associated expression. ¹²³
As a value in a FREE LOCATOR or HOLD LOCATOR statement	Locator.

Table 125. Untyped Parameter Marker Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Parameter Marker Location	Data Type
As a value for the password in a SET ENCRYPTION PASSWORD statement	VARCHAR(128)
As a value for the hint in a SET ENCRYPTION PASSWORD statement	VARCHAR(32)

Table 126. Untyped Parameter Marker Usage in Predicates

Untyped Parameter Marker Location	Data Type
Both operands of a comparison operator or DISTINCT predicate	VARGRAPHIC(16370) CCSID 1200
One operand of a comparison operator or DISTINCT predicate where the other operand is other than an untyped parameter marker or a strongly typed distinct type.	The data type of the other operand. If the other operand is a weakly typed distinct type, the source data type of the distinct type. ¹²³
One operand of a comparison operator where the other operand is a strongly typed distinct type.	Error
All operands of a BETWEEN predicate	VARGRAPHIC(16370) CCSID 1200
Two operands of a BETWEEN predicate	Same as that of the only non-parameter marker.
Only one operand of a BETWEEN predicate	Result of applying the “Rules for result data types” on page 99 on all operands that are other than untyped parameter markers, except the CCSID attribute is the CCSID of the value specified at execution time.
All operands of an IN predicate, for example, ? IN (?,?,?)	VARGRAPHIC(16370) CCSID 1200
The first operand of an IN predicate where the right hand side is a fullselect, for example, ? IN (fullselect).	Data type of the selected column
The first operand of an IN predicate where the right hand side is not a fullselect, for example, ? IN (?,A,B) or for example, ? IN (A,?,B,?).	Result of applying the “Rules for result data types” on page 99 on all operands of the IN list (operands to the right of IN keyword) that are other than untyped parameter markers, except the CCSID attribute is the CCSID of the value specified at execution time.
Any or all operands of the IN list of the IN predicate, for example, for example, A IN (?,B,?).	Result of applying the “Rules for result data types” on page 99 on all operands of the IN predicate (operands to the left and right of the IN predicate) that are other than untyped parameter markers, except the CCSID attribute is the CCSID of the value specified at execution time.
Any operands in a <i>row-value-expression</i> of an IN predicate, for example, (c1,?) IN ...	Error
Any select list items in a subquery if a <i>row-value-expression</i> is specified in an IN predicate, for example, (c1,c2) IN (SELECT ?, c1 FROM ...)	Error

Table 126. Untyped Parameter Marker Usage in Predicates (continued)

Untyped Parameter Marker Location	Data Type
First operand of the IS JSON predicate	CLOB(2G) CCSID 1208
<i>json-expression</i> or <i>sql-json-path-expression</i> of the JSON_EXISTS predicate.	CLOB(2G) CCSID 1208
All three operands of the LIKE predicate.	Match expression (operand 1) and pattern expression (operand 2) VARCHAR(32740); escape expression (operand 3) is VARCHAR(1) ¹²⁴ with the CCSID of the job.
The match expression of the LIKE predicate when either the pattern expression or the escape expression is other than an untyped parameter marker.	Either VARCHAR(32740) or VARGRAPHIC(16370) or VARBINARY(32740) depending on the data type of the first operand that is not an untyped parameter marker. The CCSID depends on the CCSID of the first operand.
The pattern expression of the LIKE predicate when either the match expression or the escape expression is other than an untyped parameter marker.	Either VARCHAR(32740) or VARGRAPHIC(16370) or VARBINARY(32740) depending on the data type of the first operand that is not an untyped parameter marker. The CCSID depends on the CCSID of the first operand.
The escape expression of the LIKE predicate when either the match expression or the pattern expression is other than an untyped parameter marker.	For information about using fixed-length variables for the value of the pattern, see “ LIKE predicate ” on page 198.
Operand of the NULL predicate	VARGRAPHIC(16370) CCSID 1200

Table 127. Untyped Parameter Marker Usage in Built-in Functions

Untyped Parameter Marker Location	Data Type
First argument of ADD_DAYS, ADD_HOURS, ADD_MINUTES, ADD_MONTHS, ADD_SECONDS, or ADD_YEARS	TIMESTAMP
Second argument of ADD_DAYS, ADD_HOURS, ADD_MINUTES, ADD_MONTHS, or ADD_YEARS	BIGINT
Second argument of ADD_SECONDS	DECFLOAT(34)
All arguments of BITAND, BITANDNOT, BITOR, BITXOR, BITNOT, COALESCE, IFNULL, LAND, LOR, MIN, MAX, NULLIF, VALUE, or XOR	Error
Any argument of COALESCE, IFNULL, LAND, LOR, MIN, MAX, NULLIF, or VALUE, or XOR where at least one argument is other than an untyped parameter marker.	Result of applying the “ Rules for result data types ” on page 99 on all arguments that are other than untyped parameter markers. If the result is a weakly typed distinct type, the source data type of the distinct type. If the result is a strongly typed distinct type, an error is returned.

Table 127. Untyped Parameter Marker Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
An argument of BITAND, BITANDNOT, BITOR, and BITXOR where the other argument is other than an untyped parameter marker.	If the other argument is SMALLINT, INTEGER, or BIGINT, the data type of the other argument. Otherwise, DECFLOAT(34).
First argument of BSON_TO_JSON	BLOB(2G)
All arguments of COMPARE_DECFLOAT, DECFLOAT_SORTKEY, NORMALIZE_DECFLOAT, QUANTIZE, and TOTALORDER	DECFLOAT(34)
First argument of DAYNAME	TIMESTAMP(12)
First argument of DECFLOAT_FORMAT	VARGRAPHIC(16370) CCSID 1200
Second argument of DECFLOAT_FORMAT	Error
First argument of HASH, HASH_MD5, HASH_SHA1, HASH_SHA256, or HASH_SHA512	DBCLOB(1G) CCSID 1200
Second argument of HASH	INTEGER
First argument of INTERPRET	BLOB(2G)
JSON-expression (when FORMAT BSON is specified) argument of JSON_ARRAY, JSON_OBJECT, JSON_QUERY, or JSON_VALUE	BLOB(2G)
JSON-expression (when FORMAT BSON is not specified), key-name-expression, or sql-json-path-expression arguments of JSON_ARRAY, JSON_OBJECT, JSON_QUERY, or JSON_VALUE	CLOB(2G) CCSID 1208
First argument of JSON_TO_BSON	CLOB(2G) CCSID 1208
Both arguments of LOCATE, POSITION, or POSSTR	DBCLOB(1G) CCSID 1200
One argument of LOCATE, POSITION, or POSSTR when the other argument is a character data type.	VARCHAR(32740) with the CCSID of the other argument
One argument of LOCATE, POSITION, or POSSTR when the other argument is a graphic data type.	VARGRAPHIC(16370) with the CCSID of the other argument
One argument of LOCATE, POSITION, or POSSTR when the other argument is a binary data type.	VARBINARY(32740)
Both the first and second arguments of LOCATE_IN_STRING or OVERLAY	DBCLOB(1G) CCSID 1200
The first or second argument of LOCATE_IN_STRING or OVERLAY when the other string argument is a character data type.	VARCHAR(32740) with the CCSID of the other argument
The first or second argument of LOCATE_IN_STRING or OVERLAY when the other string argument is a graphic data type.	VARGRAPHIC(16370) with the CCSID of the other argument
The first or second argument of LOCATE_IN_STRING or OVERLAY when the other string argument is a binary data type.	VARBINARY(32740)
The third or fourth argument of LOCATE_IN_STRING or OVERLAY	INTEGER

Table 127. Untyped Parameter Marker Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
The second argument of LPAD or RPAD	INTEGER
The third argument of LPAD or RPAD	VARCHAR(32740)
The first argument of LTRIM or RTRIM	DBCLOB(1G) CCSID 1200
The second argument of LTRIM or RTRIM	VARCHAR(32740) if the first argument is a character type; VARBINARY(32740) if the first argument is a binary type; VARGRAPHIC(16370) if the first argument is a graphic type. The CCSID depends on the CCSID of the first argument.
The argument of UPPER, LOWER, UCASE, and LCASE	DBCLOB(1G) CCSID 1200
First argument of MONTHNAME	TIMESTAMP(12)
First or second argument of MONTHS_BETWEEN	TIMESTAMP(12)
First operand of REGEXP_LIKE, REGEXP_INSTR, REGEXP_SUBSTR, REGEXP_COUNT, and REGEXP_REPLACE	DBCLOB(1G) CCSID 1200
Second operand of REGEXP_LIKE, REGEXP_INSTR, REGEXP_SUBSTR, REGEXP_COUNT, and REGEXP_REPLACE	DBCLOB(32K) CCSID 1200
Third operand of REGEXP_REPLACE	DBCLOB(32K) CCSID 1200
<i>source-string</i> operand of REGEXP_LIKE, REGEXP_COUNT, REGEXP_INSTR, REGEXP_SUBSTR, and REGEXP_REPLACE	DBCLOB(32K) CCSID 1200
<i>pattern-expression</i> of REGEXP_LIKE, REGEXP_COUNT, REGEXP_INSTR, REGEXP_SUBSTR, and REGEXP_REPLACE	DBCLOB(32K) CCSID 1200
<i>replacement-string</i> operand of REGEXP_REPLACE	DBCLOB(32K) CCSID 1200
<i>start</i> operand of REGEXP_LIKE, REGEXP_COUNT, REGEXP_INSTR, REGEXP_SUBSTR, and REGEXP_REPLACE	INTEGER
<i>flags</i> operand of REGEXP_LIKE, REGEXP_COUNT, REGEXP_INSTR, REGEXP_SUBSTR, and REGEXP_REPLACE	VARCHAR(6)
<i>occurrence</i> operand of REGEXP_INSTR, REGEXP_SUBSTR, and REGEXP_REPLACE	INTEGER
<i>return-option</i> operand of REGEXP_INSTR	INTEGER
<i>group</i> operand of REGEXP_INSTR and REGEXP_SUBSTR	INTEGER
SUBSTR (first argument)	DBCLOB(1G) CCSID 1200
SUBSTR (second and third arguments)	INTEGER
The first argument of TRANSLATE	Error

Table 127. Untyped Parameter Marker Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
The second and third arguments of TRANSLATE	VARCHAR(32740) if the first argument is a character type; VARGRAPHIC(16370) if the first argument is a graphic type. The CCSID depends on the CCSID of the first argument.
The fourth argument of TRANSLATE	VARCHAR(1) if the first argument is a character type; VARGRAPHIC(1) if the first argument is a graphic type. The CCSID depends on the CCSID of the first argument.
The first argument of TIMESTAMP or TIMESTAMP_ISO	Error
The second argument of TIMESTAMP	TIME
The first argument of TIMESTAMP_FORMAT	VARGRAPHIC(16370) CCSID 1200
The first argument of VARCHAR_FORMAT	TIMESTAMP(12)
The second argument of TIMESTAMP_FORMAT or VARCHAR_FORMAT	Error
Any argument after the first argument of VERIFY_GROUP_FOR_USER	VARCHAR(128)
First argument of XMLVALIDATE	XML ¹²⁵
First argument of XMLPARSE	CLOB(2G) or DBCLOB(1G) based on the CCSID value for the query option SQL_XML_DATA_CCSID
First argument of XMLCOMMENT	VARCHAR(32740) or VARGRAPHIC(16370) based on the CCSID value for the query option SQL_XML_DATA_CCSID
First argument of XMLTEXT	VARCHAR(32740) or VARGRAPHIC(16370) based on the CCSID value for the query option SQL_XML_DATA_CCSID
Second argument of XMLPI	VARCHAR(36740) or VARGRAPHIC(16370) based on the CCSID value for the query option SQL_XML_DATA_CCSID
First argument of XMLSERIALIZE	XML ¹²⁶
All arguments of XMLDOCUMENT	XML ¹²⁵
All arguments of XMLCONCAT	XML ¹²⁵
First, second, and third arguments of XSLTRANSFORM	XML ¹²⁶
Array index of an ARRAY	BIGINT
Unary minus	DECFLOAT(34)
Unary plus	DECFLOAT(34)
All other arguments of all other scalar functions.	Error
Argument of MEDIAN	DECFLOAT(34)

Table 127. Untyped Parameter Marker Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
First or second argument of CORRELATION, COVARIANCE, COVARIANCE_SAMP, or any of the Regression functions	DECFLOAT(34) if the other argument is DECFLOAT. Otherwise, DOUBLE.
JSON-expression (when FORMAT BSON is specified) argument of JSON_ARRAYAGG or JSON_OBJECTAGG	BLOB(2G)
JSON-expression (when FORMAT BSON is not specified) or key-name-expression argument of JSON_ARRAYAGG or JSON_OBJECTAGG	CLOB(2G) CCSID 1208
Second argument of LISTAGG	VARCHAR(32740) if the first argument is a character type; VARBINARY(32740) if the first argument is a binary type; VARGRAPHIC(16370) if the first argument is a graphic type. The CCSID depends on the CCSID of the first argument.
Argument or order by expression of PERCENTILE_CONT or PERCENTILE_DISC	DECFLOAT(34)
Arguments of all other aggregate functions	Error
JSON-expression or sql-json-path-expression argument of JSON_TABLE	CLOB(2G) CCSID 1208

Table 128. Untyped Parameter Marker Usage in User-defined Routines

Untyped Parameter Marker Location	Data Type
Argument of a function	The data type of the parameter, as defined when the function was created
Argument of a procedure	The data type of the parameter, as defined when the procedure was created

Error checking: When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is not valid, a prepared statement is not created and an error is returned.

In local and remote processing, the DLYPREP(*YES) option can cause some SQL statements to receive "delayed" errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

Reference and execution rules: Prepared statements can be referred to in the following kinds of statements, with the following restrictions shown:

Statement	The prepared statement restrictions
DESCRIBE	None
DECLARE CURSOR	Must be SELECT when the cursor is opened
EXECUTE	Must not be SELECT

¹²³ If the data type is DATE, TIME, or TIMESTAMP, then VARCHAR(32740) is used.

¹²⁴ If the escape expression is MIXED data, the data type is VARCHAR(4).

¹²⁵ The CCSID for XML is determined as described in "XML Values" on page 75.

¹²⁶ The CCSID is determined based on the attributes of the *data-type* specified on the AS clause as described in "CAST specification" on page 164. If the *data-type* is a binary string or bit data, then the SQL_XML_DATA_CCSID is used for the CCSID attribute.

A prepared statement can be executed many times. If a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.

Extended indicator usage: The EXTENDED INDICATORS clause indicates whether extended indicator variable values are enabled in the SET *assignment-clause* of an UPDATE statement, the VALUES *expression-list* of an INSERT statement, or the insert operation or update operation of a MERGE statement.

Extended indicator variables and deferred error checks: When extended indicator variables are enabled, the UNASSIGNED indicator variable value effectively causes its target column to be omitted from the statement. Because of this, validation that is normally done during statement preparation is delayed until statement execution.

Prepared statement persistence: All prepared statements are destroyed when:¹²⁷

- A CONNECT (Type 1) statement is executed.
- A DISCONNECT statement disconnects the connection with which the prepared statement is associated.
- A prepared statement is associated with a release-pending connection and a successful commit occurs.
- The associated scope (job, activation group, or program) of the SQL statement ends.

Scope of a statement: The scope of *statement-name* is the source program in which it is defined. You can only reference a prepared statement by other SQL statements that are precompiled with the PREPARE statement. For example, a program called from another separately compiled program cannot use a prepared statement that was created by the calling program.

The scope of *statement-name* is also limited to the thread in which the program that contains the statement is running. For example, if the same program is running in two separate threads in the same job, the second thread cannot use a statement that was prepared by the first thread.

Although the scope of a statement is the program in which it is defined, each package created from the program includes a separate instance of the prepared statement and more than one prepared statement can exist at run time. For example, assume a program using CONNECT (Type 2) statements connects to location X and location Y in the following sequence:

```
EXEC SQL CONNECT TO X;
EXEC SQL PREPARE S FROM :hv1;
EXEC SQL EXECUTE S;
.
.
.
EXEC SQL CONNECT TO Y;
EXEC SQL PREPARE S FROM :hv1;
EXEC SQL EXECUTE S;
```

The second prepare of S prepares another instance of S at Y.

A prepared statement can only be referenced in the same instance of the program in the program stack, unless CLOSQLCSR(*ENDJOB), CLOSQLCSR(*ENDACTGRP), or CLOSQLCSR(*ENDSQL) is specified on the CRTSQLxxx commands.

- If CLOSQLCSR(*ENDJOB) is specified, the prepared statement can be referred to by any instance of the program (that prepared the statement) on the program stack. In this case, the prepared statement is destroyed at the end of the job.
- If CLOSQLCSR(*ENDSQL) is specified, the prepared statement can be referred to by any instance of the program (that prepared the statement) on the program stack until the last SQL program on the program stack ends. In this case, the prepared statement is destroyed when the last SQL program on the program stack ends.

¹²⁷ Prepared statements may be cached and not actually destroyed. However, a cached statement can only be used if the same statement is prepared again.

- If CSQLCSR(*ENDACTGRP) is specified, the prepared statement can be referred to by all instances of the module in the program that prepared the statement until the activation group ends. In this case, the prepared statement is destroyed when the activation group ends.

Allocating the SQL descriptor: If a USING clause is specified, before the PREPARE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of result columns, a warning (SQLSTATE 01005) is returned.

PREPARE and *LIBL: Normally, any unqualified names of objects are resolved when a statement is prepared. Hence, any changes to the CURRENT SCHEMA or CURRENT PATH after the statement has been prepared have no effect on which objects will be referenced when the statement is executed or opened. However, if system naming is used and an object name is implicitly qualified with *LIBL, the object is resolved at execute or open time. Any changes to the library list after the statement is prepared but before execute or open time will affect which objects will be referenced when the statement is executed or opened.

Examples

Example 1: Prepare and execute a non-select-statement in a COBOL program. Assume the statement is contained in a variable HOLDER and that the program will place a statement string into the variable based on some instructions from the user. The statement to be prepared does not have any parameter markers.

```
EXEC SQL  PREPARE STMT_NAME FROM :HOLDER  END-EXEC.  
EXEC SQL  EXECUTE STMT_NAME  END-EXEC.
```

Example 2: Prepare and execute a non-select-statement as in example 1, except assume the statement to be prepared can contain any number of parameter markers.

```
EXEC SQL  PREPARE STMT_NAME FROM :HOLDER  END-EXEC.  
EXEC SQL  EXECUTE STMT_NAME USING DESCRIPTOR :INSERT_DA  END-EXEC.
```

Assume that the following statement is to be prepared:

```
INSERT INTO DEPARTMENT VALUES(?, ?, ?, ?, ?)
```

To insert department number G01 named COMPLAINTS, which has no manager and reports to department A00, the structure INSERT_DA should have the following values before executing the EXECUTE statement.

SQLDAID	336	
SQLDABC	4	
SQLN	4	
SQLD	4	
SQLTYPE	452	
SQLLEN	3	
SQLDATA		►G01
SQLIND		
SQLNAME		
SQLTYPE	448	
SQLLEN	29	
SQLDATA		►COMPLAINTS
SQLIND		
SQLNAME		
SQLTYPE	453	
SQLLEN	6	
SQLDATA		►1
SQLIND		
SQLNAME		
SQLTYPE	452	
SQLLEN	3	
SQLDATA		►A00
SQLIND		
SQLNAME		

RBAL3501-0

REFRESH TABLE

The REFRESH TABLE statement refreshes the data in a materialized query table. The statement deletes all rows in the materialized query table and then inserts the result rows from the *select-statement* specified in the definition of the materialized query table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement,
 - The system authority *OBJMGT on the table
 - The DELETE privilege on the table
 - The INSERT privilege on the table
 - The USAGE privilege on the schema containing the table
- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

```

    ➤ REFRESH TABLE
    ➤           ,   ↗
    ➤           ↘ table-name ↘
  
```

Description

table-name

Identifies the materialized table to be refreshed. The *table-name* must identify a materialized query table that exists at the current server. REFRESH TABLE evaluates the *select-statement* in the definition of the materialized query table to refresh the table.

Notes

Refresh use of materialized query tables: No materialized query tables are used to evaluate the *select-statement* during the processing of REFRESH TABLE statement.

Refresh isolation level: The isolation level used to evaluate the *select-statement* is either:

- the isolation level specified on the *isolation-level* clause of the *select-statement*, or
- if the *isolation-level* clause was not specified, the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued.

Number of rows: After successful execution of a REFRESH TABLE statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA) will contain the number of rows inserted into the materialized query table.

Example

Refresh the data in the TRANSCOUNT materialized query table.

```
REFRESH TABLE TRANSCOUNT
```

RELEASE (connection)

The RELEASE statement places one or more connections in the release-pending state.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

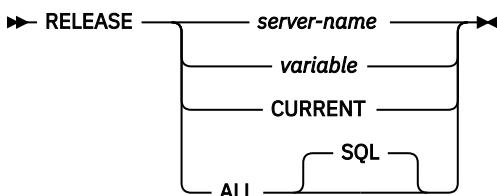

RELEASE is not allowed in a trigger or function.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

server-name or variable

Identifies a connection by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the RELEASE statement is executed, the specified server name or the server name contained in the variable must identify an existing connection of the activation group.

CURRENT

Identifies the current connection of the activation group. The activation group must be in the connected state.

ALL or ALL SQL

Identifies all existing connections of the activation group (local as well as remote connections).

An error or warning does not occur if no connections exist when the statement is executed.

An application server named ALL can only be identified by a variable or a delimited identifier.

If the RELEASE statement is successful, each identified connection is placed in the release-pending state and will therefore be ended during the next commit operation. If the RELEASE statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Notes

RELEASE and CONNECT (Type 1): Using CONNECT (Type 1) semantics does not prevent using RELEASE.

Scope of RELEASE: RELEASE does not close cursors, does not release any resources, and does not prevent further use of the connection.

Resource considerations for remote connections: Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be in the release-pending state and one that is going to be reused should not be in the release-pending state.

Connection states: ROLLBACK does not reset the state of a connection from release-pending to held.

If the current connection is in the release-pending state when a commit operation is performed, the connection is ended and the activation group is in the unconnected state. In this case, the next executed SQL statement must be CONNECT or SET CONNECTION.

RELEASE ALL places the connection to the local release-pending in the release-pending state. A connection in the release-pending state is ended during a commit operation even though it has an open cursor defined with the WITH HOLD clause.

Examples

Example 1: The connection to TOROLAB1 is not needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE TOROLAB1;
```

Example 2: The current connection is not needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE CURRENT;
```

Example 3: None of the existing connections are needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE ALL;
```

RELEASE SAVEPOINT

The RELEASE SAVEPOINT statement releases the identified savepoint and any subsequently established savepoints within a unit of work at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
►► RELEASE [TO] SAVEPOINT — savepoint-name ►►
```

Description

savepoint-name

Identifies the savepoint to release. The name must identify a savepoint that exists at the current server. The named savepoint and all the savepoints at the current server that were subsequently established in the unit of work are released. After a savepoint is released, it is no longer maintained, and rollback to the savepoint is no longer possible.

Notes

Savepoint Names: The name of the savepoint that was released can be re-used in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement specifying this same savepoint name.

Isolation Level Restriction: A RELEASE SAVEPOINT statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see [“Notes” on page 791](#) in COMMIT statement.

Example

Assume that a main routine sets savepoint A and then invokes a subroutine that sets savepoints B and C. When control returns to the main routine, release savepoint A and any subsequently set savepoints. Savepoints B and C, which were set by the subroutine, are released in addition to A.

```
RELEASE SAVEPOINT A
```

RENAME

The RENAME statement renames a table, view, or index. The name and/or the system object name of the table, view, or index can be changed.

Invocation

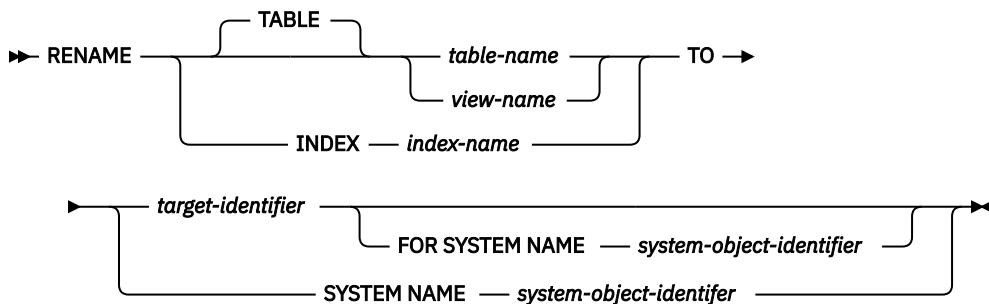

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - If the name of the object is changed:
 - The system authorities of *OBJMGT and *OBJOPR on the table, view, or index to be renamed
 - The USAGE privilege on the schema containing the table, view, or index to be renamed
 - If the system name of the object is changed:
 - The system authorities of *OBJMGT and *OBJOPR on the table, view, or index to be renamed
 - The USAGE privilege and the system authority of *UPD on the schema containing the table, view, or index to be renamed
- Database administrator authority

Syntax

Description

TABLE *table-name* or *view-name*

Identifies the table or view that will be renamed. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a catalog table or a declared temporary table. The specified name can be an alias name. The specified table or view is renamed to the new name. All privileges, constraints, indexes, triggers, views, and logical files on the table or view are preserved.

Any access plans that reference the table or view are implicitly prepared again when a program that uses the access plan is next run. Since the program refers to a table or view with the original name, if a table or view with the original name does not exist at that time, an error is returned.

INDEX *index-name*

Identifies the index that will be renamed. The *index-name* must identify an index that exists at the current server. The specified index is renamed to the new name.

Any access plans that reference the index are not affected by rename.

target-identifier

Identifies the new *table-name*, *view-name*, or *index-name* of the table, view, or index, respectively. *target-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *target-identifier* must be an unqualified SQL identifier.

SYSTEM NAME system-object-identifier

Identifies the new *system-object-identifier* of the table, view, or index, respectively. *system-object-identifier* must not be the same as a table, view, alias, or index that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

If the name of the object and the system name of the object are the same and *target-identifier* is not specified, specifying *system-object-identifier* will be the new name and system object name. Otherwise, specifying *system-object-identifier* will only affect the system name of the object and not affect the name of the object.

If both *target-identifier* and *system-object-identifier* are specified, they cannot both be valid system object names.

Notes

Effects of the statement: The specified table, view, or index is renamed to the new name. For a renamed table, all privileges and indexes on the table are preserved. For a renamed index, all privileges are preserved.

Invalidation of packages and access plans: Any access plans that refer to that table are invalidated. For more information see “[Packages and access plans](#)” on page 12.

Considerations for aliases: If an alias name is specified for *table-name*, the table must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table name after the rename.

There is no support for changing the name of an alias with the RENAME statement. To change the name to which the alias refers, the alias must be dropped and recreated.

Rename rules: The rename operation performed depends on the new name specified.

- If the new name is a valid system identifier,
 - the alternative name (if any) is removed, and
 - the system object name is changed to the new name.
- If the new name is not a valid system identifier,
 - the alternative name is added or changed to the new name, and
 - a new system object name is generated if the system object name (of the table or view) was specified as the table, view, or index to rename. For more information about generated table name rules, see “[Rules for Table Name Generation](#)” on page 994.

If an alias name is specified for *table-name*, the alias must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table after the rename. There is no support for changing the name of an alias.

Examples

Example 1: Change the name of the EMPLOYEE table to CURRENT_EMPLOYEES:

```
RENAME TABLE EMPLOYEE  
TO CURRENT_EMPLOYEES
```

Example 2: Change the name of the unique index using EMPNO, called XEMP1, to UXEMPNO:

```
RENAME INDEX XEMP1  
TO UXEMPNO
```

Example 3: Rename a table named MY_IN_TRAY to MY_IN_TRAY_94. The system object name will remain unchanged (MY_IN_TRAY).

```
RENAME TABLE MY_IN_TRAY TO MY_IN_TRAY_94  
FOR SYSTEM NAME MY_IN_TRAY
```

REVOKE (function or procedure privileges)

This form of the REVOKE statement removes the privileges on a function or procedure.

Invocation

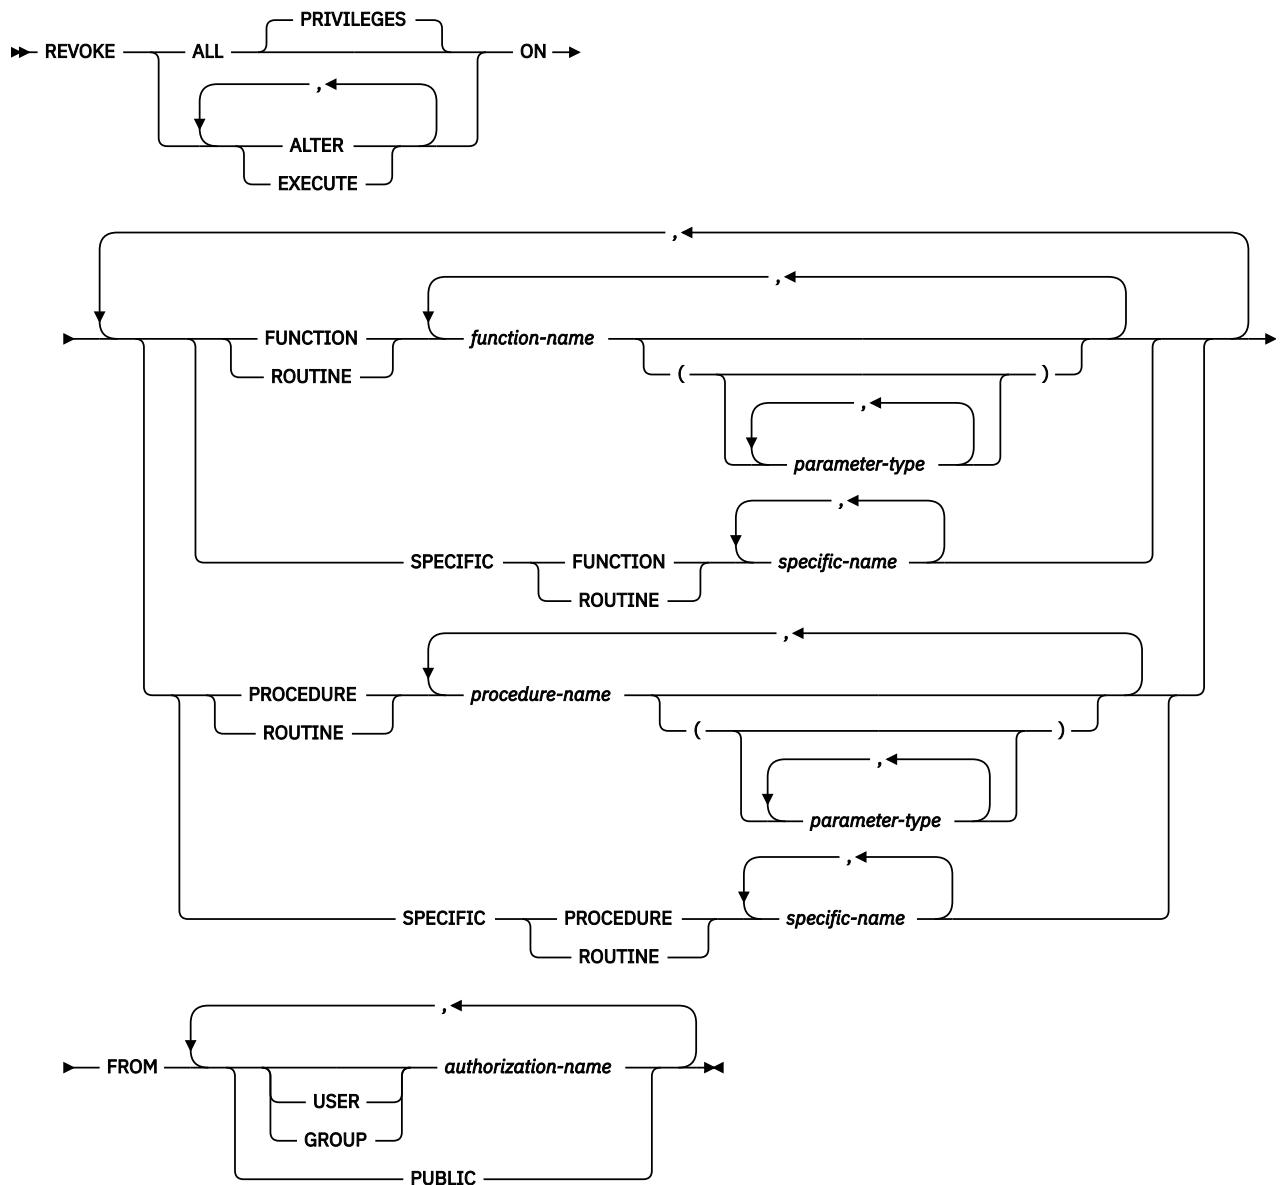

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each function or procedure identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the function or procedure
 - The USAGE privilege on the schema (or the system authority of *EXECUTE on the directory if this is a Java routine) containing the function or procedure
- Database administrator authority
- Security administrator authority

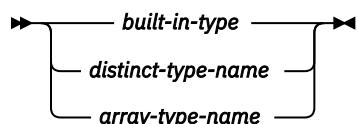

Syntax

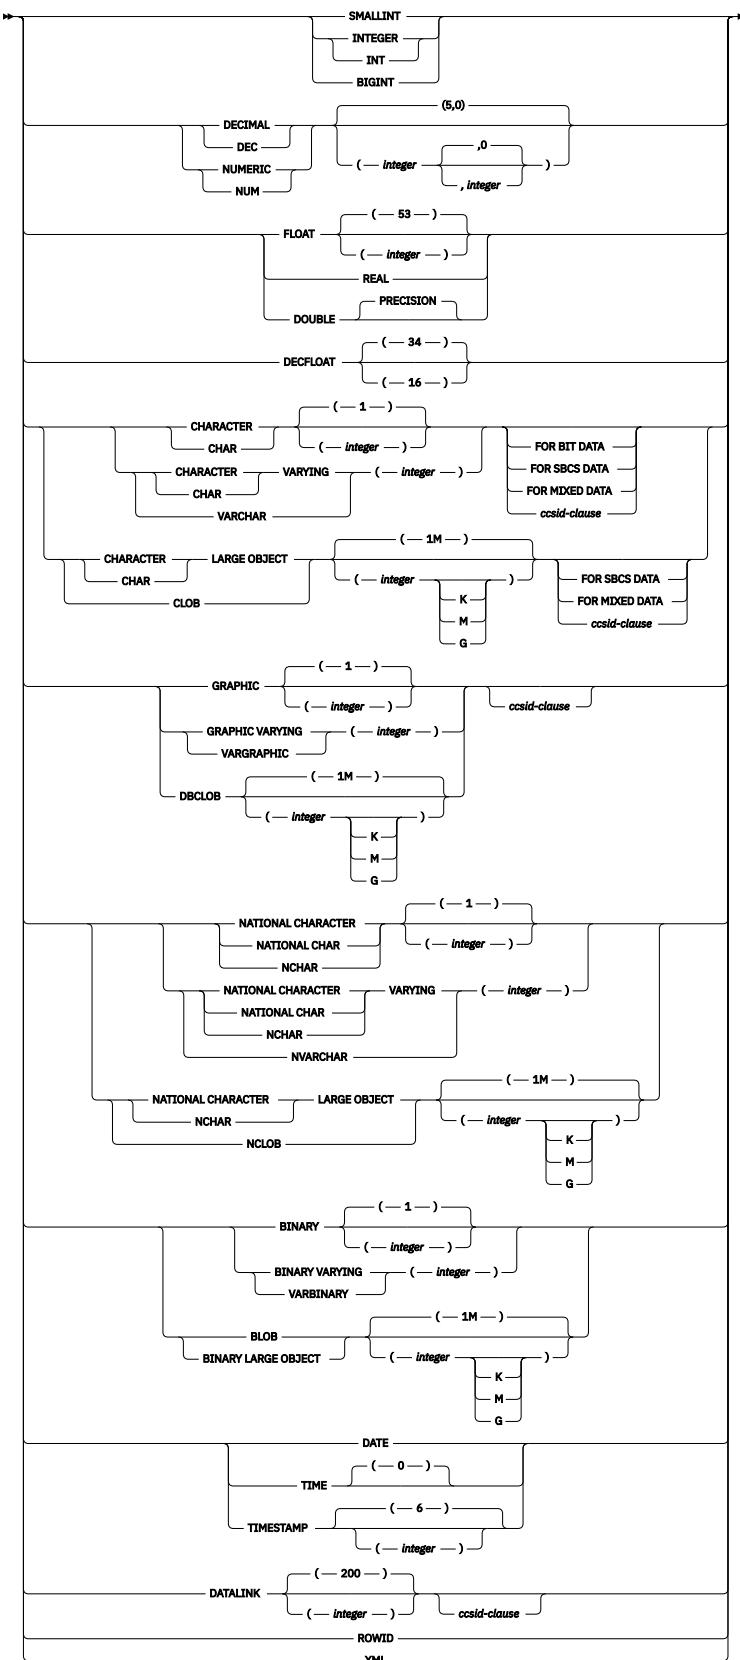

parameter-type

data-type

built-in-type

ccsid-clause

►► CCSID — *integer* ►►

Description

ALL or ALL PRIVILEGES

Revokes one or more function or procedure privileges from each *authorization-name*. The privileges revoked are those privileges on the identified functions or procedures that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a function or procedure is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use the ALTER FUNCTION, ALTER PROCEDURE, or COMMENT statement.

EXECUTE

Revokes the privilege to execute a function or procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function from which the privilege is revoked. The function must exist at the current server and it must be a user-defined function, but not a function that was implicitly generated with the creation of a distinct type. The function can be identified by its name, function signature, or specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name* (*parameter-type*, ...)

Identifies the function by its function signature, which uniquely identifies the function. The *function-name* (*parameter-type*, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be revoked. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name* () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(*parameter-type*, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure from which the privilege is revoked. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure.

The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type, ...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure.

The *procedure-name (parameter-type, ...)* must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be revoked. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name ()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see [“Authorization, privileges and object ownership” on page 15](#).

Notes

Multiple grants: If you revoke a privilege on a function or procedure, it nullifies any grant of the privilege on that function or procedure, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a function or procedure privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see [“GRANT \(function or procedure privileges\)” on page 1169](#).

Privileges revoked from either an SQL or external function or procedure are revoked from its associated program (*PGM) or service program (*SRVPGM) object. Privileges revoked from a Java external function or procedure are revoked from the associated class file or jar file. If the associated program, service program, class file, or jar file is not found when the revoke is executed, an error is returned.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.

Example

Revoke the EXECUTE privilege on procedure PROCA from PUBLIC.

```
REVOKE EXECUTE  
ON PROCEDURE PROCA  
FROM PUBLIC
```

REVOKE (package privileges)

This form of the REVOKE statement removes the privileges on a package.

Invocation

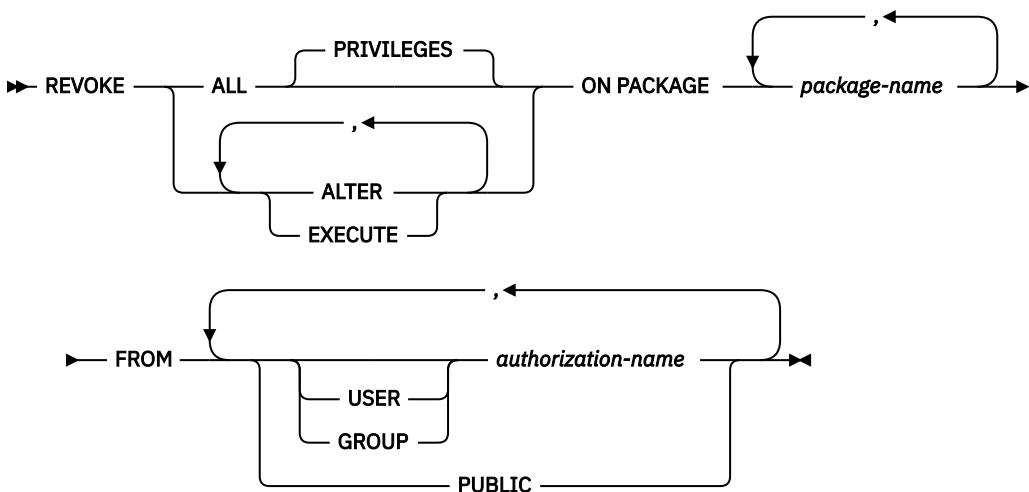

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each package identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the package
 - The USAGE privilege on the schema containing the package
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more package privileges from each *authorization-name*. The privileges revoked are those privileges on the identified packages that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a package is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use the COMMENT and LABEL statements.

EXECUTE

Revokes the privilege to execute statements in a package.

ON PACKAGE *package-name*

Identifies the package from which the EXECUTE privilege is revoked. The *package-name* must identify a package that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see “[Authorization, privileges and object ownership](#)” on page 15.

Notes

Multiple grants: If you revoke a privilege on a package, it nullifies any grant of the privilege on that package, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a package privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see “[GRANT \(package privileges\)](#)” on page 1176.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.
- The keyword PROGRAM can be used as a synonym for PACKAGE.

Example

Example 1: Revoke the EXECUTE privilege on package PKGA from PUBLIC.

```
REVOKE EXECUTE  
  ON PACKAGE PKGA  
  FROM PUBLIC
```

Example 2: Revoke the EXECUTE privilege on package RRSP_PKG from user FRANK and PUBLIC.

```
REVOKE EXECUTE  
  ON PACKAGE RRSP_PKG  
  FROM FRANK, PUBLIC
```

REVOKE (schema privileges)

This form of the REVOKE statement removes the privileges on a schema.

Invocation

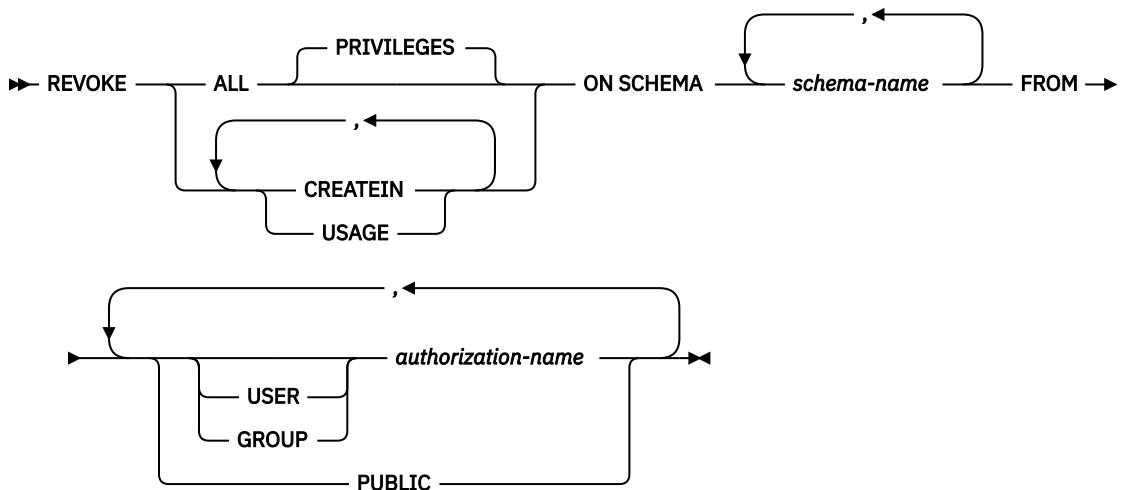

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each schema identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the schema
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more schema privileges from each *authorization-name*. The privileges revoked are those privileges on the identified schemas that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a schema is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

CREATEIN

Revokes the privilege to create objects in the schema.

USAGE

Revokes the privilege to use the schema. USAGE privilege is required to reference any objects that exist in the schema.

ON SCHEMA *schema-name*

Identifies the schema from which the privilege is revoked.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see “[Authorization, privileges and object ownership](#)” on page 15.

Notes

Multiple grants: If you revoke a privilege on a schema, it nullifies any grant of the privilege on that schema, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a schema privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “[GRANT \(schema privileges\)](#)” on page 1178.

Example

Example 1: Revoke the CREATEIN privilege on schema T_SCORES from user JONES.

```
REVOKE CREATEIN  
  ON SCHEMA T_SCORES  
  FROM JONES;
```

REVOKE (sequence privileges)

This form of the REVOKE statement removes the privileges on a sequence.

Invocation

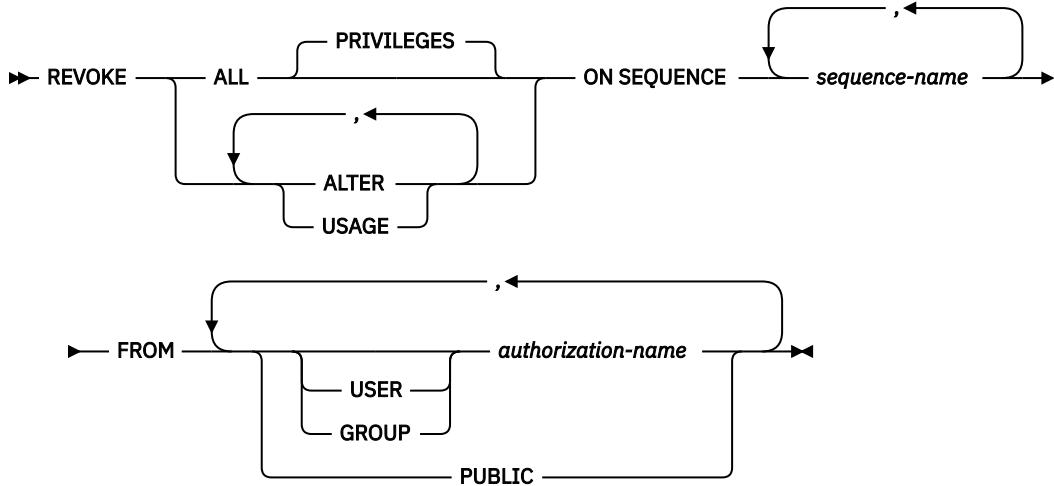

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each sequence identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the sequence
 - The USAGE privilege on the schema containing the sequence
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more sequence privileges from each *authorization-name*. The privileges revoked are those privileges on the identified sequences that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a sequence is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use the ALTER SEQUENCE, COMMENT, and LABEL statements on a sequence.

USAGE

Revokes the privilege to use the sequence in NEXT VALUE or PREVIOUS VALUE expressions.

ON SEQUENCE *sequence-name*

Identifies the sequence from which the privilege is revoked. The *sequence-name* must identify a sequence that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see [“Authorization, privileges and object ownership” on page 15](#).

Notes

Multiple grants: If you revoke a privilege on a sequence, it nullifies any grant of the privilege on that sequence, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a sequence privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “[GRANT \(sequence privileges\)](#)” on page 1181.

Example

REVOKE the USAGE privilege from PUBLIC on a sequence called ORG_SEQ.

```
REVOKE USAGE  
  ON SEQUENCE ORG_SEQ  
  FROM PUBLIC
```

REVOKE (table or view privileges)

This form of the REVOKE statement removes privileges on a table or view.

Invocation

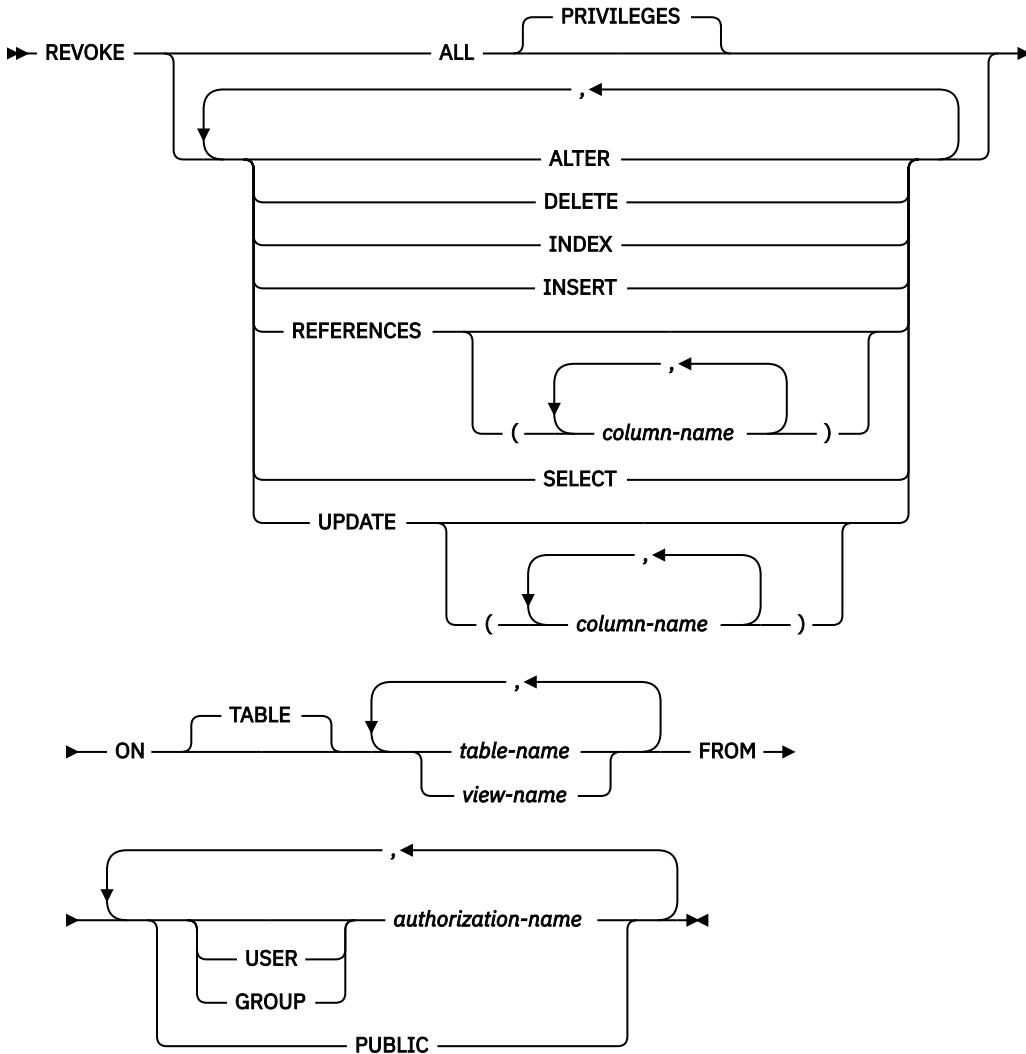

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the table or view
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more privileges from each *authorization-name*. The privileges revoked are those privileges on the identified tables and views that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a table or view is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described, but only as it applies to the tables and views named in the ON clause.

ALTER

Revokes the privilege to alter the specified table and the privilege to add a comment, add a label, or create an index on the specified table or view.

DELETE

Revokes the privilege to delete rows from the specified table or view.

INDEX

Revokes the privilege to create an index on the specified table.

INSERT

Revokes the privilege to insert rows in the specified table or view.

REFERENCES

Revokes the privilege to add a referential constraint in which the table is a parent.

REFERENCES (*column-name*,...)

Revokes the privilege to add a referential constraint using the specified column(s) in the parent key. Each column name must be an unqualified name that identifies a column in each table identified in the ON clause.

SELECT

Revokes the privilege to use the SELECT or CREATE VIEW statement.

UPDATE

Revokes the privilege to use the UPDATE statement.

UPDATE (*column-name*,...)

Revokes the privilege to update the specified columns. Each column name must be an unqualified name that identifies a column in each table identified in the ON clause.

ON *table-name* or *view-name*, ...

Identifies the table or view from which the privileges are revoked. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

***authorization-name*,...**

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see [“Authorization, privileges and object ownership” on page 15](#).

Notes

Multiple grants: If the same privilege is granted to the same user more than once, revoking that privilege from that user nullifies all those grants.

If you revoke a privilege, it nullifies any grant of that privilege, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

If more than one system authority will be revoked with an SQL privilege, and any one of the authorities cannot be revoked, then a warning occurs and no authorities will be revoked for that privilege.

Corresponding system authorities: When a table privilege is revoked, the corresponding system authorities are revoked, except:

- When revoking authorities to a table or view, *OBJOPR is revoked only when *ADD, *DLT, *READ, and *UPD have all been revoked.
- When revoking authorities to a view, authorities will not be revoked from any tables or views referenced in the fullselect of the view definition.

For information about the system authorities that correspond to SQL privileges see [“GRANT \(table or view privileges\)” on page 1183](#).

Revoking either the INDEX or ALTER privilege, revokes the system authority *OBJALTER.

Examples

Example 1: Revoke SELECT privileges on table EMPLOYEE from user ENGLES.

```
REVOKE SELECT  
ON TABLE EMPLOYEE  
FROM ENGLES
```

Example 2: Revoke update privileges on table EMPLOYEE previously granted to all users. Note that grants to specific users are not affected.

```
REVOKE UPDATE  
ON TABLE EMPLOYEE  
FROM PUBLIC
```

Example 3: Revoke all privileges on table EMPLOYEE from users PELLOW and ANDERSON.

```
REVOKE ALL  
ON TABLE EMPLOYEE  
FROM PELLOW, ANDERSON
```

Example 4: Revoke the privilege to update column_1 in VIEW1 from FRED.

```
REVOKE UPDATE(column_1)  
ON VIEW1  
FROM FRED
```

REVOKE (type privileges)

This form of the REVOKE statement removes the privileges on a type.

Invocation

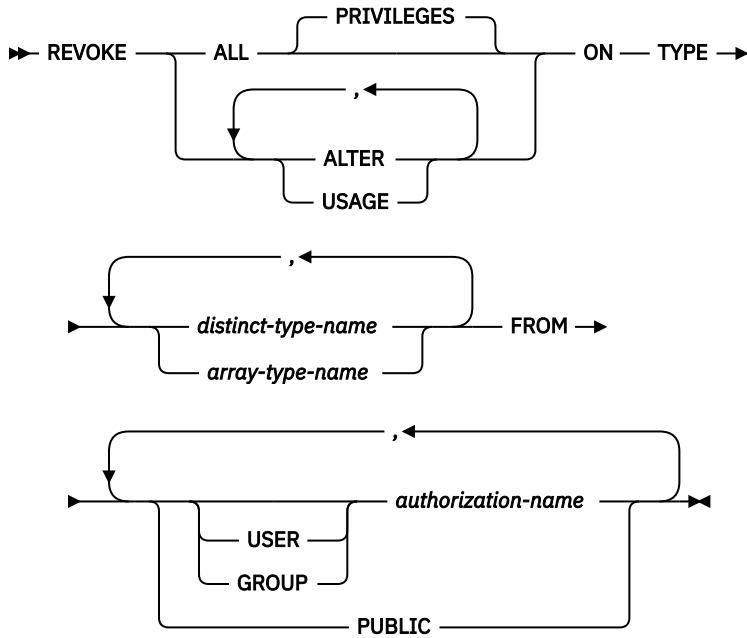

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the type
 - The USAGE privilege on the schema containing the type
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more type privileges from each *authorization-name*. The privileges revoked are those privileges on the identified user-defined types that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a type is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use the COMMENT and LABEL statements.

USAGE

Revokes the privilege to use user-defined types in tables, functions, procedures, or as the source type in a CREATE TYPE statement.

ON TYPE *distinct-type-name* or *array-type-name*

Identifies the distinct type from which the privilege is revoked. The *distinct-type-name* or *array-type-name* must identify a user-defined type that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see ["Authorization, privileges and object ownership" on page 15](#).

Notes

Multiple grants: If authorization ID A granted the same privilege to authorization ID B more than once, revoking that privilege from B nullifies all those grants.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a type privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see “[GRANT \(type privileges\)](#)” on page 1189.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Example

Revoke the USAGE privilege on distinct type SHOESIZE from user JONES.

```
REVOKE USAGE  
  ON DISTINCT TYPE SHOESIZE  
  FROM JONES
```

REVOKE (variable privileges)

This form of the REVOKE statement removes the privileges on a created global variable.

Invocation

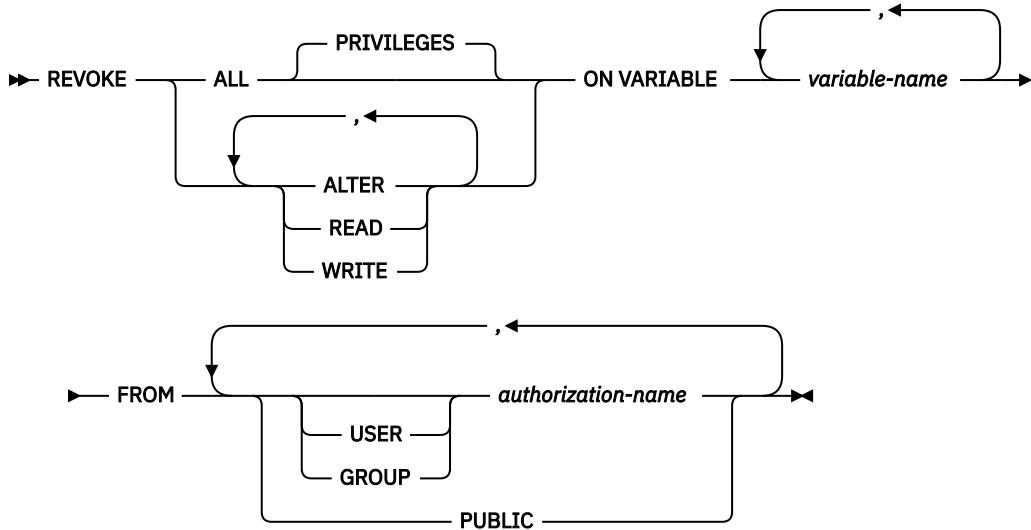

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each variable identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the global variable
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more global variable privileges from each *authorization-name*. The privileges revoked are those privileges on the identified global variables that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a global variable is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use COMMENT and LABEL statements on the specified global variables.

READ

Revokes the privilege to read the value of the specified global variables.

WRITE

Revokes the privilege to assign a value to the specified global variables.

ON VARIABLE *variable-name*

Identifies the global variables from which one or more privileges are to be revoked. Each *variable-name* must identify a global variable that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see [“Authorization, privileges and object ownership” on page 15](#).

Notes

Multiple grants: If you revoke a privilege on a variable, it nullifies any grant of the privilege on that variable, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a global variable privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “[GRANT \(variable privileges\)](#)” on page 1192.

Example

REVOKE the WRITE privilege on a global variable MYSCHHEMA.MYJOB_PRINTER from user ZUBIRI.

```
REVOKE WRITE  
ON VARIABLE MYSCHHEMA.MYJOB_PRINTER  
FROM ZUBIRI
```

REVOKE (XML schema privileges)

This form of the REVOKE statement removes the privileges on an XSR object.

Invocation

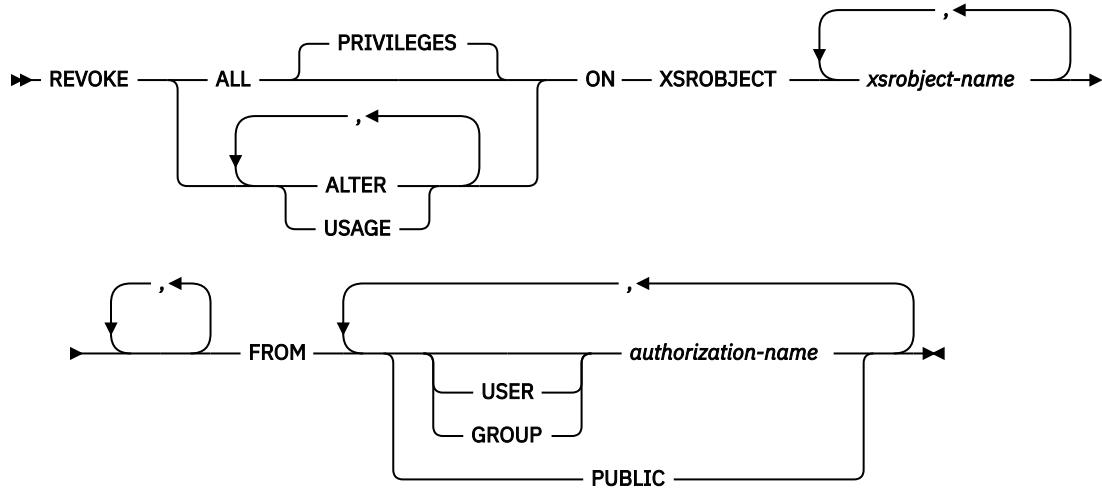

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each XSR object identified in the statement:
 - Every privilege specified in the statement
 - The system authority of *OBJMGT on the XSR object
 - The USAGE privilege on the schema containing the XSR object
- Database administrator authority
- Security administrator authority

Syntax

Description

ALL or ALL PRIVILEGES

Revokes one or more XSR object privileges from each *authorization-name*. The privileges revoked are those privileges on the identified XSR objects that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on an XSR object is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revokes the privilege to use the COMMENT and LABEL statements.

USAGE

Revokes the privilege to use an XSR object.

ON XSROBJECT *xsobject-name*

Identifies the XSR objects for which the privilege is revoked. The *xsobject-name* must identify an XSR object that exists at the current server.

FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

GROUP

Specifies that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see [“Authorization, privileges and object ownership” on page 15](#).

Notes

Multiple grants: If you revoke a privilege on an XSR object, it nullifies any grant of the privilege on that XSR object, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When an XSR object privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see “[GRANT \(XML schema privileges\)](#)” on page 1194.

Example

Revoke the USAGE privilege on XSR object XMLSCHEMA from PUBLIC.

```
REVOKE USAGE  
  ON XSRSOBJECT XMLSCHEMA  
  FROM PUBLIC
```

ROLLBACK

The ROLLBACK statement is used to back out changes.

The ROLLBACK statement can be used to either:

- End a unit of work and back out all the relational database changes that were made by that unit of work. If relational databases are the only recoverable resources used by the application process, ROLLBACK also ends the unit of work.
- Back out only the changes made after a savepoint was set within the unit of work without ending the unit of work. Rolling back to a savepoint enables selected changes to be undone.

Invocation

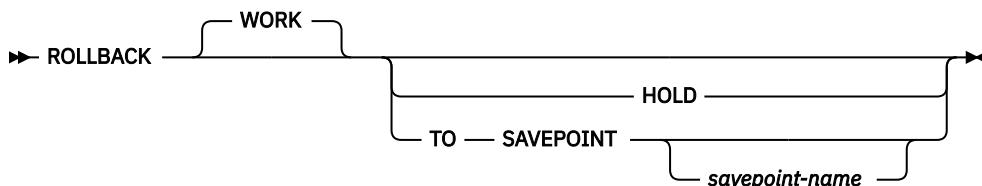

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

ROLLBACK is not allowed in a trigger if the trigger program and the triggering program run under the same commitment definition. ROLLBACK is not allowed in a procedure if the procedure is called on a Distributed Unit of Work connection to a remote application server or if the procedure is defined as ATOMIC. ROLLBACK is not allowed in a function.

Authorization

None required.

Syntax

Description

When ROLLBACK is used without the TO SAVEPOINT clause, the unit of work in which it is executed is ended. All changes made by SQL schema statements and SQL data change statements during the unit of work are backed out. For more information see Chapter 7, “Statements,” on page 655.

The generation of identity values is not under transaction control. Values generated and consumed by inserting rows into a table that has an identity column are independent of executing the ROLLBACK statement. Also, executing the ROLLBACK statement does not affect the IDENTITY_VAL_LOCAL function.

Special registers are not under transaction control. Executing a ROLLBACK statement does not affect special registers.

Sequences are not under transaction control. Executing a ROLLBACK statement does not affect the current value generated and consumed by executing a NEXT VALUE expression.

Global variables are not under transaction control. Executing a ROLLBACK statement does not affect the value of any instantiated global variable.

The impact of ROLLBACK or ROLLBACK TO SAVEPOINT on the contents of a declared temporary table is determined by the setting of the ON ROLLBACK clause of the DECLARE GLOBAL TEMPORARY TABLE statement.

WORK

ROLLBACK WORK has the same effect as ROLLBACK.

HOLD

Specifies a hold on resources. If specified, currently open cursors are not closed cursors whether they are declared with a HOLD option or not. All resources acquired during the unit of work, except locks on the rows of tables, are held. Locks on specific rows implicitly acquired during the unit of work, however, are released.

At the end of a ROLLBACK HOLD, the cursor position is the same as it was at the start of the unit of work, unless

- ALWBLK(*ALLREAD) was specified when the program or routine that contains the cursor was created
- ALWBLK(*READ) and ALWCPYDTA(*OPTIMIZE) were specified when the program or routine that contains the cursor was created

TO SAVEPOINT

Specifies that the unit of work is not to be ended and that only a partial rollback (to a savepoint) is to be performed. If a savepoint name is not specified, rollback is to the last active savepoint. For example, if in a unit of work, savepoints A, B, and C are set in that order and then C is released, ROLLBACK TO SAVEPOINT causes a rollback to savepoint B. If no savepoint is active, an error is returned.

savepoint-name

Identifies the savepoint to which to roll back. The name must identify a savepoint that exists at the current server.

After a successful ROLLBACK TO SAVEPOINT, the savepoint continues to exist.

All database changes (including changes made to declared temporary tables that were declared with the ON ROLLBACK PRESERVE ROWS clause) that were made after the savepoint was set are backed out. All locks and LOB locators are retained.

The impact on cursors resulting from a ROLLBACK TO SAVEPOINT depends on the statements within the savepoint:

- If the savepoint contains SQL schema statements on which a cursor is dependent, the cursor is closed. Attempts to use such a cursor after a ROLLBACK TO SAVEPOINT results in an error.
- Otherwise, the cursor is not affected by the ROLLBACK TO SAVEPOINT (it remains open and positioned).

Any savepoints at the current server that are set after the one to which rollback is performed are released. The savepoint to which rollback is performed is not released.

Notes

Recommended coding practices: Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

Other effects of rollback: Rollback without the TO SAVEPOINT clause and HOLD clause causes the following to occur:

- All cursors that were opened during the unit of work are closed whether they are declared with a HOLD option or not.
- All LOB locators, including those that are held, are freed.
- All locks acquired under this unit of work's commitment definition are released.

ROLLBACK has no effect on the state of connections.

Implicit ROLLBACK: The ending of the default activation group causes an implicit rollback. Thus, an explicit COMMIT or ROLLBACK statement should be issued before the end of the default activation group.

A ROLLBACK is automatically performed when:

1. The default activation group ends without a final COMMIT being issued.
2. A failure occurs that prevents the activation group from completing its work (for example, a power failure).

If the unit of work is in the prepared state because a COMMIT was in progress when the failure occurred, a rollback is not performed. Instead, resynchronization of all the connections involved in the unit of work will occur. For more information, see the [Commitment control topic collection](#).

3. A failure occurs that causes a loss of the connection to an application server (for example, a communications line failure).

If the unit of work is in the prepared state because a COMMIT was in progress when the failure occurred, a rollback is not performed. Instead, resynchronization of all the connections involved in the unit of work will occur. For more information, see the [Commitment control topic collection](#).

4. An activation group other than the default activation group ends abnormally.

Row lock limit: A unit of work may include the processing of up to and including 4 million rows, including rows retrieved during a SELECT INTO or FETCH statement, and rows inserted, deleted, or updated as part of INSERT, DELETE, and UPDATE operations.¹²⁸

Unaffected statements: The commit and rollback operations do not affect the DROP SCHEMA statement, and this statement is not, therefore, allowed if the current isolation level is anything other than No Commit (NC).

ROLLBACK restrictions: A ROLLBACK statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see the [commitment definition discussion in the COMMIT statement](#).

A commit or rollback in a user-defined function in a secondary thread is not allowed.

ROLLBACK has no effect on the state of connections.

¹²⁸ Unless you specified COMMIT(*CHG) or COMMIT(*CS), in which case these rows are not included in this total.

¹²⁹ This limit also includes:

- Any rows accessed or changed through files opened under commitment control through high-level language file processing
- Any rows deleted, updated, or inserted as a result of a trigger or CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.

If, within a unit of work, a CLOSE is followed by a ROLLBACK, all changes made within the unit of work are backed out. The CLOSE itself is not backed out and the file is not reopened.

Examples

Example 1: See the “[Example](#)” on page 792 under COMMIT for examples using the ROLLBACK statement.

Example 2: After a unit of recovery started, assume that three savepoints A, B, and C were set and that C was released:

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;  
...  
SAVEPOINT B ON ROLLBACK RETAIN CURSORS;  
...  
SAVEPOINT C ON ROLLBACK RETAIN CURSORS;  
RELEASE SAVEPOINT C
```

Roll back all database changes only to savepoint A:

```
ROLLBACK WORK TO SAVEPOINT A
```

If a savepoint name was not specified (that is, ROLLBACK WORK TO SAVEPOINT), the rollback would be to the last active savepoint that was set, which is B.

SAVEPOINT

The SAVEPOINT statement sets a savepoint within a unit of work to identify a point in time within the unit of work to which relational database changes can be rolled back.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
►► SAVEPOINT — savepoint-name ——————  
                                                          ON ROLLBACK RETAIN CURSORS →  
                                                          UNIQUE  
                                                          —————  
                                                          ON ROLLBACK RETAIN LOCKS      1  
                                                          —————  
                                                          —————→
```

Notes:

¹ The ROLLBACK options can be specified in any order.

Description

savepoint-name

Identifies a new *savepoint*. The specified *savepoint-name* cannot begin with 'SYS'.

UNIQUE

Specifies that the application program cannot reuse the savepoint name within the unit of work. An error occurs if a savepoint with the same name as *savepoint-name* already exists within the unit of work.

Omitting UNIQUE indicates that the application can reuse the savepoint name within the unit of work. If *savepoint-name* identifies a savepoint that already exists within the unit of work and the savepoint was not created with the UNIQUE option, the existing savepoint is destroyed and a new savepoint is created. Destroying a savepoint to reuse its name for another savepoint is not the same as releasing the savepoint. Reusing a savepoint name destroys only one savepoint. Releasing a savepoint with the RELEASE SAVEPOINT statement releases the savepoint and all savepoints that have been subsequently set.

ON ROLLBACK RETAIN CURSORS

Specifies that cursors that are opened after the savepoint is set are not closed upon rollback to the savepoint.

- If SQL schema statements are executed for a table or view within the scope of the SAVEPOINT statement, any cursor that references that table or view is closed. Attempts to use such a cursor after a ROLLBACK TO SAVEPOINT results in an error.
- Otherwise, the cursor is not affected by the ROLLBACK TO SAVEPOINT (it remains open and positioned).

Although these cursors remain open after rollback to the savepoint, they might not be usable. For example, if rolling back to the savepoint causes the insertion of a row on which the cursor is positioned to be rolled back, using the cursor to update or delete the row results in an error.

ON ROLLBACK RETAIN LOCKS

Specifies that any locks that are acquired after the savepoint is set are not released on rollback to the savepoint.

Notes

Savepoint persistence: A savepoint, S, is destroyed when:

- A COMMIT or ROLLBACK (without a TO SAVEPOINT clause) statement is executed.
- A ROLLBACK TO SAVEPOINT statement is executed that specifies savepoint S or a savepoint that was established earlier than S in the unit of work.
- A RELEASE SAVEPOINT statement is executed that specifies savepoint S or a savepoint that was established earlier than S in the unit of work.
- A SAVEPOINT statement specifies the same name as an existing savepoint that was not created with the UNIQUE keyword.

Effect on INSERT: In an application, inserts may be buffered. The buffer will be flushed when SAVEPOINT, ROLLBACK, or RELEASE TO SAVEPOINT statements are issued.

SAVEPOINT restriction: A SAVEPOINT statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see “[Notes](#)” on page 791 in COMMIT statement.

Example

Assume that you want to set three savepoints at various points in a unit of work. Name the first savepoint A and allow the savepoint name to be reused. Name the second savepoint B and do not allow the name to be reused. Because you no longer need savepoint A when you are ready to set the third savepoint, reuse A as the name of the savepoint.

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
.
.
.
SAVEPOINT B UNIQUE ON ROLLBACK RETAIN CURSORS;
.
.
.
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
```

SELECT

The SELECT statement is a form of query. It can be embedded in an SQLJ application program or issued interactively.

For detailed information, see “[select-clause](#)” on page 598 and Chapter 6, “Queries,” on page 597.

SELECT INTO

The SELECT INTO statement produces a result table consisting of at most one row, and assigns the values in that row to variables.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

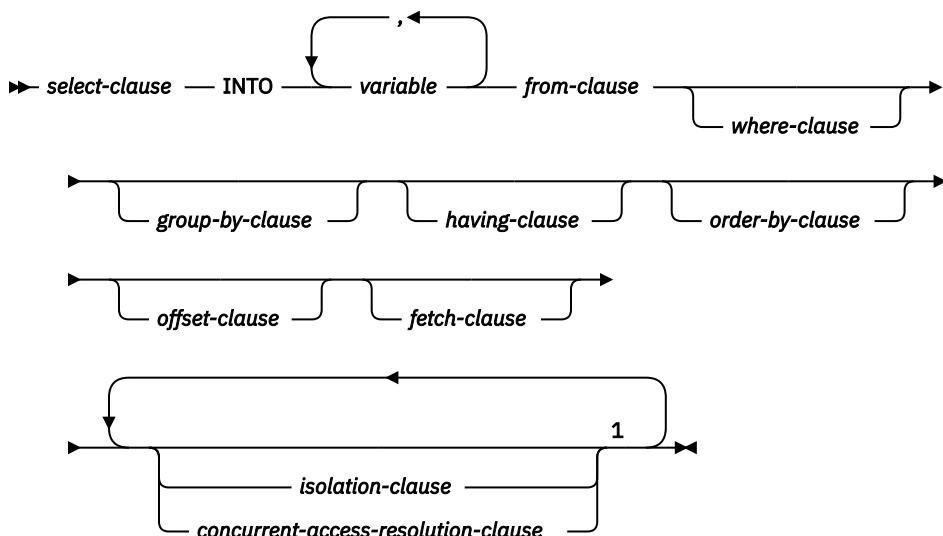

- For each table or view identified in the statement,
 - The SELECT privilege on the table or view, and
 - The USAGE privilege on the schema containing the table or view
- Database administrator authority

If a global variable is specified in the INTO variable list, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

Notes:

¹ Each clause may be specified only once.

Description

The result table is derived by evaluating the *isolation-clause*, *concurrent-access-resolution-clause*, *from-clause*, *where-clause*, *group-by-clause*, *having-clause*, *order-by-clause*, *offset-clause*, *fetch-clause*, and *select-clause*, in this order.

See [Chapter 6, “Queries,” on page 597](#) for a description of the *select-clause*, *from-clause*, *where-clause*, *group-by-clause*, *having-clause*, *order-by-clause*, *offset-clause*, *fetch-clause*, *isolation-clause*, and *concurrent-access-resolution-clause*.

INTO variable...

Identifies one or more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. In the operational form of the INTO clause, a reference to a host structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on. The data type of each variable must be compatible with its corresponding column.

Notes

Variable assignment: Each assignment to a variable is performed according to the retrieval assignment rules described in [“Assignments and comparisons” on page 83](#).¹³⁰ If the number of variables is less than the number of values in the row, an SQL warning (SQLSTATE 01503) is returned (and the SQLWARN3 field of the SQLCA is set to 'W'). Note that there is no warning if there are more variables than the number of result columns. If a value is null, an indicator variable must be provided for that value.

If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result may be returned in the indicator variable associated with the variable, if an indicator variable is provided. For further information, see [“Variables” on page 128](#).

If an assignment error occurs, the value of that variable and any following variables is unpredictable. Any values that have already been assigned to variables remain assigned.

Multiple assignments: If more than one variable is specified in the INTO clause, the query is completely evaluated before the assignments are performed. Thus, references to a *variable* in the select list are always the value of the *variable* prior to any assignment in the SELECT INTO statement.

Empty result table: If the result table is empty, the statement assigns '02000' to the SQLSTATE variable and does not assign values to the variables.

Result tables with more than one row: If more than one row satisfies the search condition, statement processing is terminated and an error is returned (SQLSTATE 21000). If an error occurs because the result table has more than one row, values may or may not be assigned to the variables. If values are assigned to the variables, the row that is the source of the values is undefined and not predictable.

Result column evaluation considerations: If an error occurs while evaluating a result column in the select list of a SELECT INTO statement, as the result of an arithmetic expression (such as division by zero, or overflow) or a numeric or character conversion error, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to the value of -2. Processing of the statement continues and a warning is returned. If an indicator variable is not provided, an error is returned and no more values are assigned to variables. It is possible that some values have already been assigned to variables and will remain assigned when the error is returned.

When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, depending on how much of the value would have to be truncated, a warning or an error is returned. See [“Datetime assignments” on page 90](#) for details.

¹³⁰ If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see [“Standards compliance” on page xix](#).

Examples

Example 1: Using a COBOL program statement, put the maximum salary (SALARY) from the EMPLOYEE table into the host variable MAX-SALARY (DECIMAL(9,2)).

```
EXEC SQL  SELECT MAX(SALARY)
           INTO :MAX-SALARY
           FROM EMPLOYEE WITH CS
END-EXEC.
```

Example 2: Using a Java program statement, select the row from the EMPLOYEE table on the connection context 'ctx' with an employee number (EMPNO) value the same as that stored in the host variable HOST_EMP (java.lang.String). Then put the last name (LASTNAME) and education level (EDLEVEL) from that row into the host variables HOST_NAME (String) and HOST_EDUCATE (Integer).

```
#sql [ctx] { SELECT LASTNAME, EDLEVEL
              INTO :HOST_NAME, :HOST_EDUCATE
              FROM EMPLOYEE
              WHERE EMPNO = :HOST_EMP   };
```

Example 3: Put the row for employee 528671, from the EMPLOYEE table, into the host structure EMPREC. Assume that the row will be updated later and should be locked when the query executes.

```
EXEC SQL  SELECT *
           INTO :EMPREC
           FROM EMPLOYEE
           WHERE EMPNO = '528671'
           WITH RS USE AND KEEP EXCLUSIVE LOCKS
END-EXEC.
```

SET CONNECTION

The SET CONNECTION statement establishes the current server of the activation group by identifying one of its existing connections.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

SET CONNECTION is not allowed in a trigger or function.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

```
►► SET CONNECTION —————— server-name —————— ►►
                                |                                |
                                |                                variable |
```

Description

server-name or variable

Identifies the connection by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable with a length attribute that is not greater than 18.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

Let S denote the specified server name or the server name contained in the variable. S must identify an existing connection of the application process. If S identifies the current connection, the state of S and all other connections of the application process are unchanged, but information about S is placed in the SQLERRP field of the SQLCA. The following rules apply when S identifies a dormant connection.

If the SET CONNECTION statement is successful:

- Connection S is placed in the current state.
- S is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the *connection-information-items* in the SQL Diagnostics Area.
- Information about application server S is also placed in the SQLERRP field of the SQLCA. If the application server is an IBM relational database product, the information has the form *pppvrrm*, where:
 - *ppp* identifies the product as follows:
 - ARI for Db2 for VSE and VM
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for all other Db2 products
 - *vv* is a two-digit version identifier such as '04'
 - *rr* is a two-digit release identifier such as '01'
 - *m* is a one-digit modification level such as '0'

For example, if the application server is Version 4 of Db2 for z/OS, the value of SQLERRP is 'DSN04010'.

- Additional information about the connection is available from the DB2_CONNECTION_STATUS and DB2_CONNECTION_TYPE connection information items in the SQL Diagnostics Area.

The DB2_CONNECTION_STATUS connection information item indicates the status of connection for this unit of work. It will have one of the following values:

- 1 - Committable updates can be performed on the connection for this unit of work.
- 2 - No committable updates can be performed on the connection for this unit of work.

The DB2_CONNECTION_TYPE connection information item indicates the type of connection. It will have one of the following values:

- 1 - Connection is to a local relational database.
- 2 - Connection is to a remote relational database with the conversation unprotected.
- 3 - Connection is to a remote relational database with the conversation protected.
- 4 - Connection is to an application requester driver program.

- Additional information about the connection is also placed in the SQLERRD(4) field of the SQLCA. SQLERRD(4) will contain a value indicating whether the application server allows committable updates

to be performed. Following is a list of values and their meanings for the SQLERRD(4) field of the SQLCA on the CONNECT :

- 1 - Committable updates can be performed and either the connection uses an unprotected conversation, is a connection established to an application requester driver program using a CONNECT (Type 1) statement, or is a local connection established using a CONNECT (Type 1) statement.
- 2 - No committable updates can be performed; conversation is unprotected.
- 3 - It is unknown if committable updates can be performed; conversation is protected.
- 4 - It is unknown if committable updates can be performed; conversation is unprotected.
- 5 - It is unknown if committable updates can be performed and the connection is either a local connection established using a CONNECT (Type 2) statement or a connection to an application requester driver program established using a CONNECT (Type 2) statement.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to Appendix B, "SQL Communication Area" for a description of the information in the SQLERRMC field.
- Any previously current connection is placed in the dormant state.

If the SET CONNECTION statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Notes

SET CONNECTION for CONNECT (Type 1): The use of CONNECT (Type 1) statements does not prevent the use of SET CONNECTION, but the statement either fails or does nothing because dormant connections do not exist.

Status after connection is restored: When a connection is used, made dormant, and then restored to the current state in the same unit of work, the status of locks, cursors, and prepared statements for that connection reflects its last use by the activation group.

Local connections: A SET CONNECTION to a local connection will fail if the current independent auxiliary Storage pool (IASP) name space does not match the local connection's relational database.

Example

Execute SQL statements at TOROLAB1, execute SQL statements at TOROLAB2, and then execute more SQL statements at TOROLAB1.

```
EXEC SQL CONNECT TO TOROLAB1;
```

(Execute statements referencing objects at TOROLAB1)

```
EXEC SQL CONNECT TO TOROLAB2;
```

(Execute statements referencing objects at TOROLAB2)

```
EXEC SQL SET CONNECTION TOROLAB1;
```

(Execute statements referencing objects at TOROLAB1)

The first CONNECT statement creates the TOROLAB1 connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION statement returns it to the current state.

SET CURRENT DEBUG MODE

The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

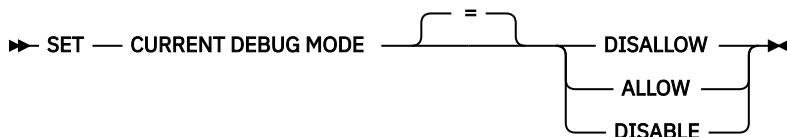

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

Description

The value of CURRENT DEBUG MODE is replaced by the specified keyword:

DISALLOW

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

ALLOW

Procedures will be created so they can be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is ALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

DISABLE

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISABLE, the procedure cannot be subsequently altered to change the DEBUG MODE attribute.

Notes

Transaction considerations: The SET CURRENT DEBUG MODE statement is not a committable operation. ROLLBACK has no effect on the current debug mode.

Initial current debug mode: The initial value of the current debug mode is DISALLOW.

Current debug mode scope: The scope of the current debug mode is the activation group.

Example

Example 1: The following statement sets the CURRENT DEBUG MODE to allow subsequent procedures created by the CREATE PROCEDURE (SQL) statement to be debuggable.

```
SET CURRENT DEBUG MODE = ALLOW
```

Example 2: The following statement sets the CURRENT DEBUG MODE to disallow subsequent procedures created by the CREATE PROCEDURE (SQL) statement to be debuggable and to prevent those procedures from being altered to make them debuggable.

```
SET CURRENT DEBUG MODE = DISABLE
```

SET CURRENT DECFLOAT ROUNDING MODE

The SET CURRENT DECFLOAT ROUNDING MODE statement changes the value of the CURRENT DECFLOAT ROUNDING MODE special register.

Invocation

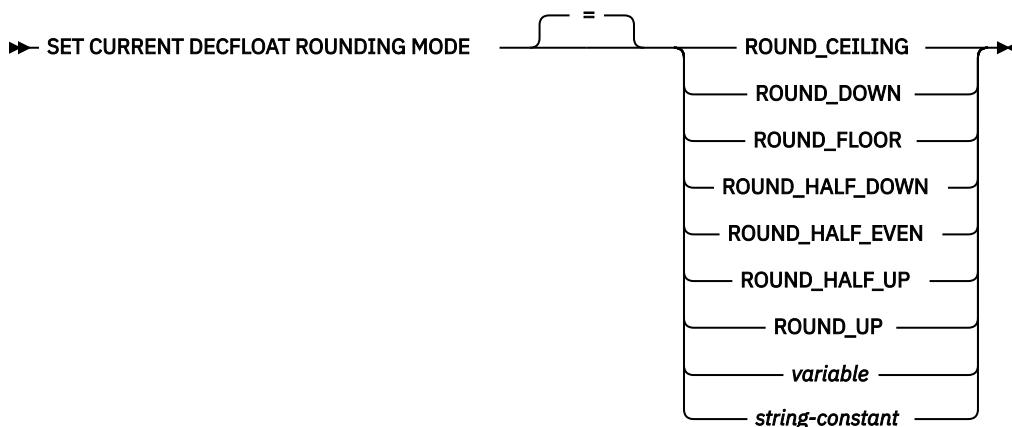

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

ROUND_CEILING

Round toward +Infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

ROUND_DOWN

Round toward zero (truncation). The discarded digits are ignored.

ROUND_FLOOR

Round toward -Infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of the discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by one.

ROUND_HALF_DOWN

Round to nearest; if equidistant, round down. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

This rounding mode is not recommended when creating a portable application since it is not supported by the IEEE draft standard for floating-point arithmetic.

ROUND_HALF_EVEN

Round to nearest; if equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise (they represent exactly half), the result coefficient is unaltered if its rightmost digit is even or incremented by one (rounded up) if its rightmost digit is odd (to make an even digit).

ROUND_HALF_UP

Round to nearest; if equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

ROUND_UP

Round away from zero. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

This rounding mode is not recommended when creating a portable application since it is not supported by the IEEE draft standard for floating-point arithmetic.

string-constant

A character constant that contains a specification of the rounding mode.

variable

Specifies a variable which contains the value for the CURRENT DECFLOAT ROUNDING MODE. The content is not folded to uppercase.

The variable:

- Must be a character-string or Unicode graphic-string variable.
- Must not be followed by an indicator variable.
- Must contain one of the seven rounding mode keywords.
- Must be padded on the right with blanks if the variable is fixed length.

Notes

Transaction considerations: The SET CURRENT DECFLOAT ROUNDING MODE statement is not a committable operation. ROLLBACK has no effect on the CURRENT DECFLOAT ROUNDING MODE.

Initial CURRENT DECFLOAT ROUNDING MODE: The initial value of CURRENT DECFLOAT ROUNDING MODE in an activation group is established by the first SQL statement that is executed in the activation group.

- If the first SQL statement in an activation group is executed from an SQL program or SQL package, the CURRENT DECFLOAT ROUNDING MODE special register is set to the value of the DECFLTRND parameter.
- Otherwise, the initial value is ROUND_HALF_EVEN.

CURRENT DECFLOAT ROUNDING MODE scope is activation group.

Examples

Example 1: Set the CURRENT DECFLOAT ROUNDING MODE special register to ROUND_DOWN using a string constant and using a keyword.

```
SET CURRENT DECFLOAT ROUNDING MODE = 'ROUND_DOWN'
```

```
SET CURRENT DECFLOAT ROUNDING MODE = ROUND_DOWN
```

SET CURRENT DEGREE

The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It must not be specified in REXX.

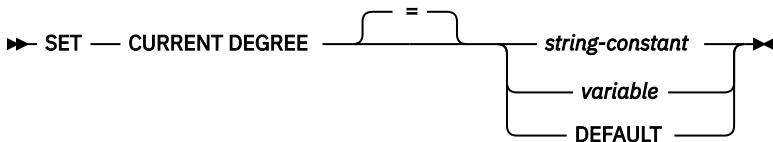

Authorization

The privileges held by the authorization ID of the statement must include *JOBCTL special authority or be authorized to the SQL Administrator function of IBM i through Application Administration in System i Navigator. The Change Function Usage (CHGFCNUSG) command, with a function ID of QIBM_DB_SQLADM, can also be used to change the list of authorized users.

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

The value of CURRENT DEGREE is replaced by the value of the string constant or variable.

string-constant

Specifies a character string constant. The content is not folded to uppercase.

The length of the *string-constant* must not exceed 5 after trimming any leading and trailing blanks.

variable

Specifies a variable that contains the value for CURRENT DEGREE.

The variable:

- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the *variable* must not be greater than 5 after trimming any leading and trailing blanks.
- Must not be the null value.
- Must have contents in uppercase characters. All characters are case-sensitive and are not converted to uppercase characters.

DEFAULT

If the PARALLEL_DEGREE parameter in a current query options file (QAQQINI) is specified, the CURRENT DEGREE will be reset to the PARALLEL_DEGREE. Otherwise, the CURRENT DEGREE will be reset from the degree specified by the QQRYDEGREE system value.

The value of the string constant or variable must be one of the following:

1

No parallel processing is allowed.

2 through 32767

Specifies the degree of parallelism that will be used.

ANY

Specifies that the database manager can choose to use any number of tasks for either I/O or SMP parallel processing.

Use of parallel processing and the number of tasks used is determined based on the number of processors available in the system, this job's share of the amount of active memory available in the pool in which the job is run, and whether the expected elapsed time for the operation is limited by CPU processing or I/O resources. The database manager chooses an implementation that minimizes elapsed time based on the job's share of the memory in the pool.

NONE

No parallel processing is allowed.

MAX

The database manager can choose to use any number of tasks for either I/O or SMP parallel processing. MAX is similar to ANY except the database manager assumes that all active memory in the pool can be used.

I/O

The CQE optimizer can use parallel I/O methods only. This setting does not require the SMP feature. The SQE optimizer considers I/O parallelism with or without this setting.

Notes

Transaction considerations: The SET CURRENT DEGREE statement is not a committable operation. ROLLBACK has no effect on CURRENT DEGREE.

Initial current degree: The initial value of CURRENT DEGREE is equal to the parallelism degree in effect from the CHGQRYA CL command, PARALLEL_DEGREE parameter in the current query options file (QAQQINI), or the QQRYDEGREE system value.

Parallelism degree precedence: The parallelism degree can be controlled in several ways. The actual parallelism degree used is determined as follows:

- If a SET CURRENT DEGREE statement or a CHGQRYA CL command with a DEGREE keyword has been executed, the parallelism degree specified by the most recent of either is the value of CURRENT DEGREE.
- If neither a SET CURRENT DEGREE statement nor a CHGQRYA CL command with a DEGREE keyword has been executed,
 - If a current query options file (QAQQINI) with a PARALLEL_DEGREE parameter has been specified, the parallelism degree specified by the QAQQINI file is the value of CURRENT DEGREE.
 - Otherwise, the parallelism degree specified by the QQRYDEGREE system value is the value of CURRENT DEGREE.

For more information, see [Database Performance and Query Optimization](#) topic collection.

Current degree scope: The scope of CURRENT DEGREE is the job.

Parallel limitations: If the DB2 Symmetric Multiprocessing feature is not installed, a warning is returned and parallelism is not used.

Some SQL statements cannot use parallelism.

Example

Example 1: The following statement sets the CURRENT DEGREE to inhibit parallelism.

SET CURRENT DEGREE = '1'

Example 2: The following statement sets the CURRENT DEGREE to allow parallelism.

SET CURRENT DEGREE = 'ANY'

SET CURRENT IMPLICIT XMLPARSE OPTION

The SET CURRENT IMPLICIT XMLPARSE OPTION statement changes the value of the CURRENT IMPLICIT XMLPARSE OPTION special register.

Invocation

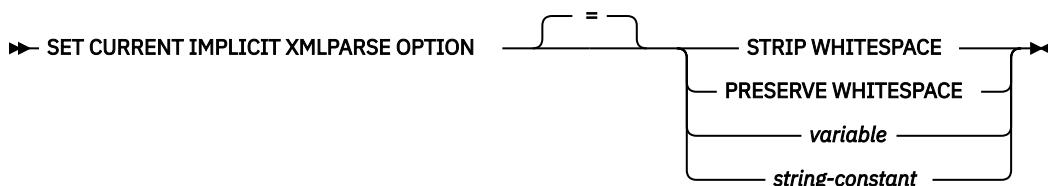

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
 - Database administrator authority

Syntax

Description

STRIP WHITESPACE

Whitespace is removed on implicit XMLPARSE.

PRESERVE WHITESPACE

Whitespace is not removed on implicit XMLPARSE.

variable

Specifies a variable which contains the value for the CURRENT IMPLICIT XMLPARSE OPTION. The content is folded to uppercase.

The variable:

- Must be a character-string or Unicode graphic-string variable.
 - Must not be followed by an indicator variable.
 - Must contain one of the two implicit XMLPARSE options.
 - Must be padded on the right with blanks if the variable is fixed length.

string-constant

A character constant that contains a specification of the implicit XMLPARSE option. The value must be a left justified string that is either 'STRIP WHITESPACE' or 'PRESERVE WHITESPACE' with exactly one blank character between the keywords. The content is folded to uppercase.

Notes

Transaction considerations: The SET CURRENT IMPLICIT XMLPARSE OPTION statement is not a committable operation. ROLLBACK has no effect on the CURRENT IMPLICIT XMLPARSE OPTION.

Initial CURRENT IMPLICIT XMLPARSE OPTION: The initial value of CURRENT IMPLICIT XMLPARSE OPTION is 'STRIP WHITESPACE'.

Both static and dynamic statements are affected by this special register.

The CURRENT IMPLICIT XMLPARSE OPTION scope is the connection.

Example

Set the value of the CURRENT IMPLICIT XMLPARSE OPTION special register to 'PRESERVE WHITESPACE'.

```
SET CURRENT IMPLICIT XMLPARSE OPTION = PRESERVE WHITESPACE
```

SET CURRENT TEMPORAL SYSTEM_TIME

The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
►► SET CURRENT TEMPORAL SYSTEM_TIME [ = ] NULL | expression
```

Description

NULL

Specifies the null value.

expression

An expression that can be assigned to a TIMESTAMP(12). The expression must not contain a scalar fullselect or a function that is non-deterministic, external action, or modifies SQL data.

Notes

Transaction considerations: The SET CURRENT TEMPORAL SYSTEM_TIME statement is not a committable operation. ROLLBACK has no effect on CURRENT TEMPORAL SYSTEM_TIME.

CURRENT TEMPORAL SYSTEM_TIME scope: The scope of the CURRENT TEMPORAL SYSTEM_TIME special register is the activation group and connection.

Examples

Example 1: Set the CURRENT TEMPORAL SYSTEM_TIME special register to the previous month.

```
SET CURRENT TEMPORAL SYSTEM_TIME = CURRENT TIMESTAMP - 1 MONTH
```

Example 2: Set the CURRENT TEMPORAL SYSTEM_TIME special register to the null value.

```
SET CURRENT TEMPORAL SYSTEM_TIME = NULL
```

SET DESCRIPTOR

The SET DESCRIPTOR statement sets information in an SQL descriptor.

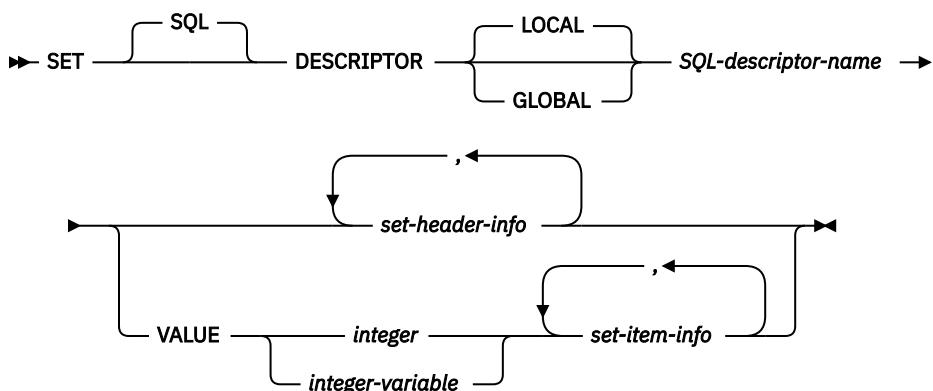

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

set-header-info

```
►► COUNT — = — constant-1 —  
                  variable-1 —
```

set-item-info

CARDINALITY	=	constant-2
DATA	=	variable-2
DATETIME_INTERVAL_CODE		
DB2_CCSID		
INDICATOR		
LENGTH		
LEVEL		
PRECISION		
SCALE		
TYPE		
USER_DEFINED_TYPE_CATALOG		
USER_DEFINED_TYPE_NAME		
USER_DEFINED_TYPE_SCHEMA		

Description

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The information provided is set into the descriptor known in this local scope.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information provided is set into the descriptor known to any program that executes using the same database connection.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

set-header-info

Sets attributes into the SQL descriptor. The same descriptor item must not be specified more than once in a single SET DESCRIPTOR statement.

VALUE

Specifies the item number for which the specified information is set. If the item number is greater than the maximum number of items allocated for the descriptor or the item number is less than 1, an error is returned.

integer

An integer constant in the range of 1 to the number of items allocated in the SQL descriptor.

integer-variable

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be SMALLINT, INTEGER, BIGINT, or DECIMAL or NUMERIC with a scale of zero. The value of variable must be in the range of 1 to the maximum number of items allocated in the SQL descriptor.

set-item-info

Sets information about a specific item into the SQL descriptor. The same descriptor item must not be specified more than once in a single SET DESCRIPTOR statement. Items that are not applicable to the specified type are ignored.

set-header-info

COUNT

A count of the number of items that will be specified in the descriptor.

variable-1

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the COUNT header item as specified in [Table 101 on page 1141](#). The variable is assigned (using storage assignment rules) to the COUNT header item. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#).

constant-1

Identifies a constant value used to set the COUNT header item. The data type of the constant must be compatible with the COUNT header item as specified in [Table 101 on page 1141](#). The constant is assigned (using storage assignment rules) to the COUNT header item. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#).

set-item-info

CARDINALITY

Specifies the cardinality for the item. This is only allowed when TYPE is an array.

DATA

Specifies the value for the data described by the item descriptor. If the value of INDICATOR is negative, then the value of DATA is undefined. The assigned value cannot be a constant.

DATETIME_INTERVAL_CODE

Specifies the specific datetime data type. DATETIME_INTERVAL_CODE must be specified if TYPE is set to 9.

- 1**
DATE
- 2**
TIME
- 3**
TIMESTAMP

DB2_CCSID

Specifies the CCSID of character, graphic, XML, or datetime data. The value is not applicable for all other data types. If the DB2_CCSID is not specified or 0 is specified:

- For XML data, the SQL_XML_DATA_CCSID QAQQINI option setting will be used.
- Otherwise, the CCSID of the variable will be determined by the CCSID of the job.

INDICATOR

Specifies the value for the indicator. A non-negative indicates a DATA value will be provided for this descriptor item. When extended indicator variables are not enabled, a negative value indicates the value described by this descriptor item is the null value. If not set, the value of INDICATOR is 0. When extended indicator variables are enabled:

- -1, -2, -3, -4, or -6 indicates the value described by this descriptor item is the null value.
- -5 indicates the value described by this descriptor item is the DEFAULT value.
- -7 indicates the value described by this descriptor item is the UNASSIGNED value.
- 0 or a positive value indicates a DATA value will be provided for this descriptor item.

LENGTH

Specifies the maximum length of the data. If the data type is a character or graphic string type, XML type, or a datetime type, the length represents the number of characters (not bytes). If the data type is a binary string or any other type, the length represents the number of bytes. If LENGTH is not specified, a default length will be used. For a description of the defaults, see [Table 129 on page 1301](#).

LEVEL

The level of the item descriptor.

- 0**
Item is a primary descriptor entry.
- 1**
Item is for a secondary descriptor entry. This is for an array entry.

PRECISION

Specifies the precision for descriptor items of data type DECIMAL, NUMERIC, DECFLOAT, DOUBLE, REAL, FLOAT, and TIMESTAMP. If PRECISION is not specified, a default precision will be used. For a description of the defaults, see [Table 129 on page 1301](#).

SCALE

Specifies the scale for descriptor items of data type DECIMAL or NUMERIC. If SCALE is not specified, a default scale will be used. For a description of the defaults, see [Table 129 on page 1301](#).

TYPE

Specifies a data type code representing the data type of the descriptor item. For a description of the data type codes and lengths, see [Table 102 on page 1143](#). Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

USER_DEFINED_TYPE_CATALOG

Specifies the server name of the user-defined type. If USER_DEFINED_TYPE_CATALOG is specified, it must be equal to the current server. Otherwise, the USER_DEFINED_TYPE_CATALOG is the current server.

USER_DEFINED_TYPE_NAME

Specifies the name of the user-defined data type. Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

USER_DEFINED_TYPE_SCHEMA

Specifies the schema containing the user-defined type. Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

variable-2

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in [Table 101 on page 1141](#). The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#).

When setting the DATA item, in general the variable must have the same data type, length, precision, scale, and CCSID as specified in [Table 101 on page 1141](#). For variable-length types, the variable length must not be less than the LENGTH in the descriptor. For C nul-terminated types, the variable length must be at least one greater than the LENGTH in the descriptor.

constant-2

Identifies a constant value used to set the descriptor item. The data type of the constant must have the same data type, length, precision, scale, and CCSID as specified in [Table 101 on page 1141](#). The constant is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#).

If the descriptor item to be set is DATA, *constant-2* cannot be specified.

Notes

Default values for descriptor items: The following table represents the default values for LENGTH, PRECISION, and SCALE, if they are not specified for a descriptor item.

Table 129. Default LENGTH, PRECISION, and SCALE			
Data Type	LENGTH	PRECISION	SCALE
DECIMAL and NUMERIC		5	0
FLOAT		53	0
DECFLOAT		34	
CHARACTER, VARCHAR, and CLOB	1		
GRAPHIC, VARGRAPHIC, and DBCLOB	1		
BINARY, VARBINARY, and BLOB	1		
DATE	10		
TIME	8		
TIMESTAMP	26	6	
XML	1		

Example

Example 1: Set the number of items in descriptor 'NEWDA' to the value in :numitems.

```
EXEC SQL SET DESCRIPTOR 'NEWDA'  
COUNT = :numitems;
```

Example 2: Set the value of the type and length for the first item descriptor of descriptor 'NEWDA'

```
SET DESCRIPTOR 'NEWDA'  
  VALUE 1 TYPE  = :dtype,  
        LENGTH = :olength;
```

SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the default password and hint that will be used by the encryption and decryption functions. The password is not associated with authentication and is only used for data encryption and decryption.

For information about using this statement, see “[ENCRYPT_AES](#)” on page 335, “[ENCRYPT_RC2 or ENCRYPT](#)” on page 339, “[ENCRYPT_TDES](#)” on page 341, and “[DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR and DECRYPT_DB](#)” on page 324.

Invocation

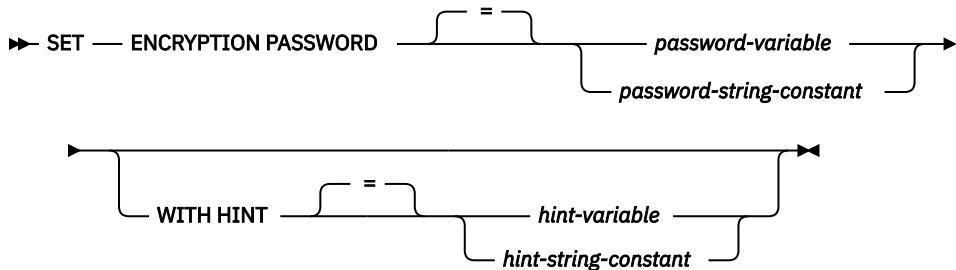

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

password-variable

Specifies a variable that contains an encryption password.

The variable:

- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the variable must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

password-string-constant

A character constant. The length of the constant must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value. The literal form of the password is not allowed in static SQL or REXX.

WITH HINT

Indicates that a value is specified that will help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value is specified, the hint is used as the default for encryption functions. The hint can subsequently be retrieved for an encrypted value using the GETHINT function. If this clause is not specified and a hint is not explicitly specified on the encryption function, no hint will be embedded in encrypted data result.

hint-variable

Specifies a variable that contains an encryption password hint.

The variable:

- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the variable must not be greater than 32. If an empty string is specified, the default encryption password hint is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

hint-string-constant

A character constant. The length of the constant must not be greater than 32. If an empty string is specified, the default encryption password hint is set to no value.

Notes

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string-constant* in the source for a program, procedure, or function. Instead, use a variable.

When connected to a remote relational database, the specified password itself is sent "in the clear". That is, the password itself is not encrypted. To protect the password in these cases, consider using a communications encryption mechanism such as IPSEC (or TLS if connecting between IBM i products).

Transaction considerations: The SET ENCRYPTION PASSWORD statement is not a committable operation. ROLLBACK has no effect on the default encryption password or default encryption password hint.

Initial encryption password value: The initial value of both the default encryption password and the default encryption password hint is the empty string ("").

Encryption password scope: The scope of the default encryption password and default encryption password hint is the activation group and connection.

Example

Set the ENCRYPTION PASSWORD to the value in :hv1.

```
SET ENCRYPTION PASSWORD :hv1
```

SET OPTION

The SET OPTION statement establishes the processing options to be used for SQL statements.

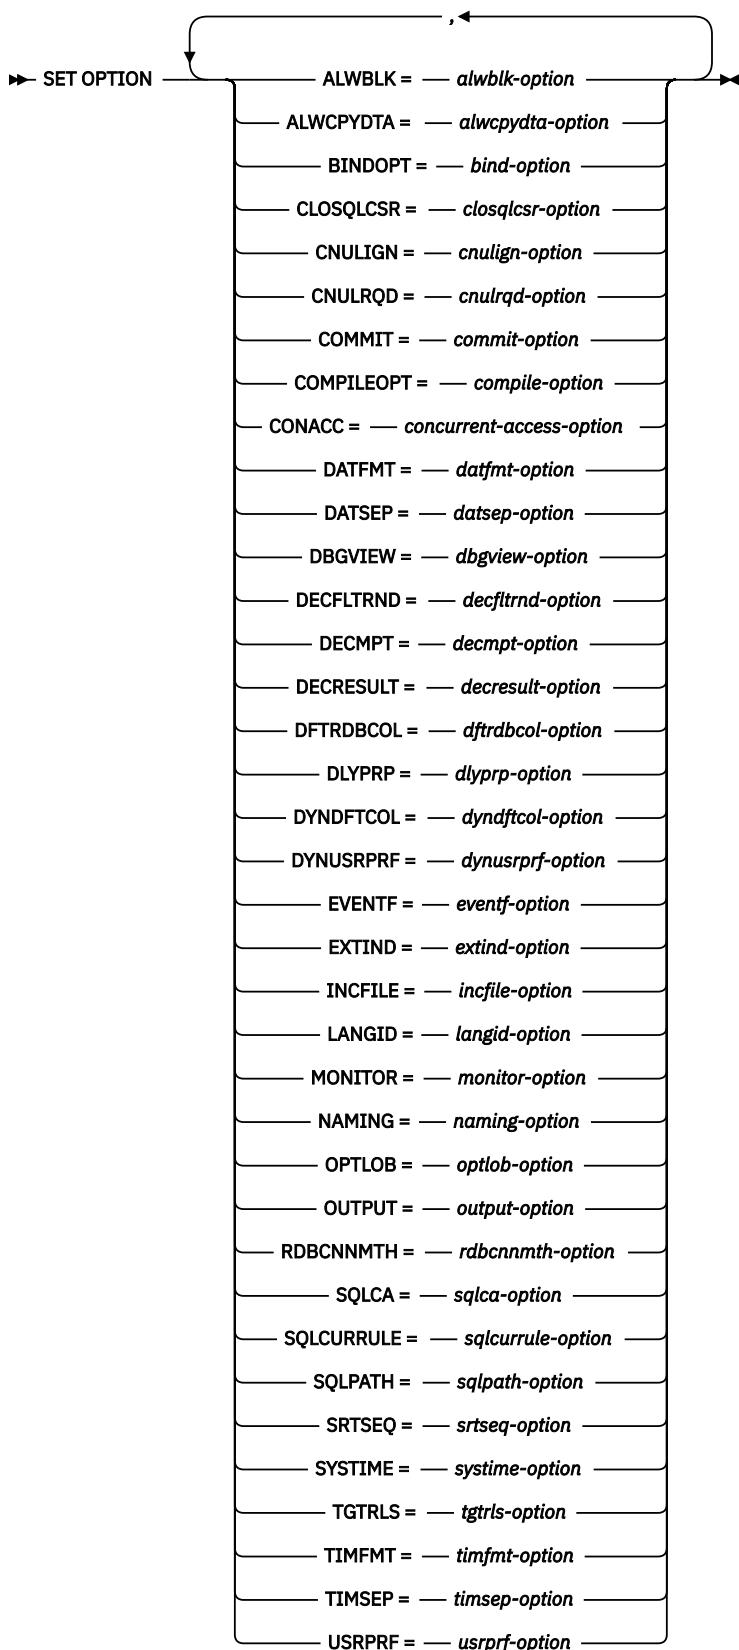

Invocation

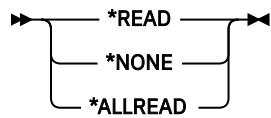

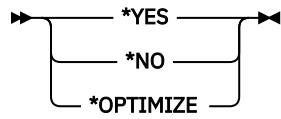

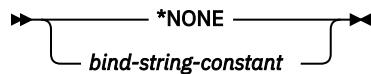

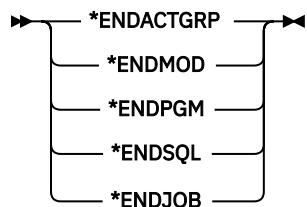

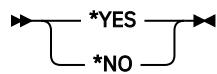

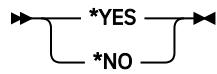

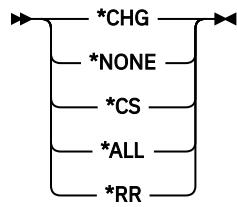

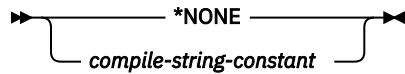

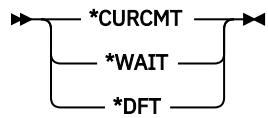

This statement can be used in a REXX procedure or embedded in an application program. If used in a REXX procedure, it is an executable statement. If embedded in an application program, it is not executable and must precede any other SQL statements. This statement cannot be dynamically prepared.

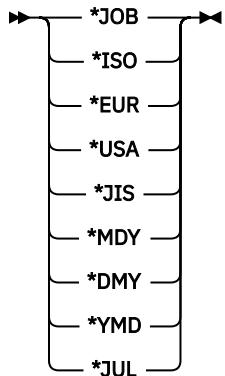

Authorization

None required.

usrprf-option

Description

ALWBLK

Specifies whether the database manager can use row blocking and the extent to which blocking can be used for read-only cursors. This option will be ignored in REXX.

***ALLREAD**

Rows are blocked for read-only cursors if COMMIT is *NONE, *CHG, or *CS. All cursors in a program that are not explicitly able to be updated are opened for read-only processing even though EXECUTE or EXECUTE IMMEDIATE statements may be in the program.

Specifying *ALLREAD:

- Allows row blocking under commitment control level *CHG and *CS in addition to the blocking allowed for *READ.
- Can improve the performance of almost all read-only cursors in programs, but limits queries in the following ways:
 - The Rollback (ROLLBACK) command, a ROLLBACK statement in host languages, or the ROLLBACK HOLD SQL statement does not reposition a read-only cursor when:
 - ALWBLK(*ALLREAD) was specified when the program or routine that contains the cursor was created
 - ALWBLK(*READ) and ALWCPYDTA(*OPTIMIZE) were specified when the program or routine that contains the cursor was created
 - Dynamic running of a positioned UPDATE or DELETE statement (for example, using EXECUTE IMMEDIATE), cannot be used to update a row in a cursor unless the DECLARE statement for the cursor includes the FOR UPDATE clause.

***NONE**

Rows are not blocked for retrieval of data for cursors.

Specifying *NONE:

- Guarantees that the data retrieved is current.
- May reduce the amount of time required to retrieve the first row of data for a query.
- Stops the database manager from retrieving a block of data rows that is not used by the program when only the first few rows of a query are retrieved before the query is closed.
- Can degrade the overall performance of a query that retrieves a large number of rows.

***READ**

Rows are blocked for read-only retrieval of data for cursors when:

- *NONE is specified on the COMMIT parameter, which indicates that commitment control is not used.
- The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor.

Specifying *READ can improve the overall performance of queries that meet the above conditions and retrieve a large number of rows.

ALWCPYDTA

Specifies whether a copy of the data can be used in a SELECT statement. This option will be ignored in REXX.

***OPTIMIZE**

The system determines whether to use the data retrieved directly from the database or to use a copy of the data. The decision is based on which method provides the best performance. If COMMIT is *CHG or *CS and ALWBLK is not *ALLREAD, or if COMMIT is *ALL or *RR, then a copy of the data is used only when it is necessary to run a query.

***YES**

A copy of the data is used only when necessary.

***NO**

A copy of the data is not allowed. If a temporary copy of the data is required to perform the query, an error message is returned.

BINDOPT

Specifies additional parameters to be used on the CRTPGM or CRTSRVPGM CL command that is used when creating an SQL function, SQL procedure, or SQL trigger. The BINDOPT string is added to the CRTPGM or CRTSRVPGM CL command generated by the precompiler. The contents of the string are not validated. The bind command will issue an error if any parameter is incorrect. The following bind options cannot be specified in this string since they are set by the precompiler: ACTGRP, ALWRINZ, AUT, ENTMOD, EXPORT, MODULE, REPLACE, STGMDL, TEXT, TGTRLS, and USRPRF.

This option is only allowed in an SQL function, SQL procedure, or SQL trigger. This option will be ignored in REXX.

***NONE**

No additional parameters will be used on the CRTPGM or CRTSRVPGM CL command.

bind-string-constant

A character constant of no more than 5000 characters containing the bind options.

CLOSEQLCSR

Specifies when SQL cursors are implicitly closed, SQL prepared statements are implicitly discarded, and LOCK TABLE locks are released. SQL cursors are explicitly closed when you issue the CLOSE, COMMIT, or ROLLBACK (without HOLD) SQL statements. This option will be ignored in REXX.

*ENDACTGRP and *ENDMOD are for use by ILE programs and modules, SQL functions, SQL procedures, or SQL triggers. *ENDPGM, *ENDSQL, and *ENDJOB are for use by non-ILE programs.

SQL scalar functions, SQL procedures, and SQL triggers use *ENDMOD as the default. SQL table functions are always created using *ENDACTGRP.

***ENDACTGRP**

SQL cursors are closed, SQL prepared statements are implicitly discarded, and LOCK TABLE locks are released when the activation group ends.

***ENDMOD**

SQL cursors are closed and SQL prepared statements are implicitly discarded when the module is exited. LOCK TABLE locks are released when the first SQL program on the call stack ends. Note that a cursor may only be logically closed and will only be physically closed when the first program with SQL leaves the stack and only if that program was not compiled with *ENDACTGRP.

***ENDPGM**

SQL cursors are closed and SQL prepared statements are discarded when the program ends. LOCK TABLE locks are released when the first SQL program on the call stack ends.

***ENDSQL**

SQL cursors remain open between calls and can be fetched without running another SQL OPEN. One of the programs higher on the call stack must have run at least one SQL statement. SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the first SQL program on the call stack ends. If *ENDSQL is specified for a program that is the first SQL program called (the first SQL program on the call stack), the program is treated as if *ENDPGM was specified.

***ENDJOB**

SQL cursors remain open between calls and can be fetched without running another SQL OPEN. The programs higher on the call stack do not need to have run SQL statements. SQL cursors are left open, SQL prepared statements are preserved, and LOCK TABLE locks are held when the first SQL program on the call stack ends. SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the job ends.

CNULIGN

Specifies whether a NUL-terminator is ignored for character and graphic host variables. This option will only be used for SQL statements in C and C++ programs.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

***YES**

Character and graphic host variables defined as NUL-terminated will be treated as fixed length variables for INSERT and UPDATE statements. NUL-terminators are considered part of the data.

***NO**

NUL-terminated character and graphic host variables use NUL-terminators for INSERT and UPDATE statements.

CNULRQD

Specifies whether a NUL-terminator is returned for character and graphic host variables. This option will only be used for SQL statements in C and C++ programs.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

***YES**

Output character and graphic host variables always contain the NUL-terminator. If there is not enough space for the NUL-terminator, the data is truncated and the NUL-terminator is added. Input character and graphic host variables require a NUL-terminator.

***NO**

For output character and graphic host variables, the NUL-terminator is not returned when the host variable is exactly the same length as the data. Input character and graphic host variables do not require a NUL-terminator.

COMMIT

Specifies the isolation level to be used. In REXX, files that are referred to in the source are not affected by this option. Only tables, views, and packages referred to in SQL statements are affected. For more information about isolation levels, see ["Isolation level" on page 23](#)

***CHG**

Specifies the isolation level of Uncommitted Read.

***NONE**

Specifies the isolation level of No Commit. If the DROP SCHEMA statement is included in a REXX procedure, *NONE must be used.

***CS**

Specifies the isolation level of Cursor Stability.

***ALL**

Specifies the isolation level of Read Stability.

***RR**

Specifies the isolation level of Repeatable Read.

COMPILEOPT

Specifies additional parameters to be used on the compiler command. The COMPILEOPT string is added to the compiler command built by the precompiler. If 'INCDIR' is anywhere in the string, the precompiler will call the compiler using the SRCSTMF parameter. The contents of the string is not validated. The compiler command will issue an error if any parameter is incorrect. Using any of the keywords that the precompiler passes to the compiler will cause the compiler command to fail because of duplicate parameters. Refer to the [Embedded SQL Programming topic collection](#) for a list of parameters that the precompiler generates for the compiler command. This option will be ignored in REXX.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

***NONE**

No additional parameters will be used on the compiler command.

character-string

A character constant of no more than 5000 characters containing the compiler options.

CONACC

Specifies the concurrent access resolution to use for select statements.

***CURCMT**

Specifies that the database manager is to use the currently committed version of data when encountering a row that is in the process of being updated or deleted. Rows that are in the process of being inserted are skipped. This value will be honored when possible for isolation level of *CS.

***WAIT**

Specifies to wait for a commit or rollback for data that is in the process of being updated or deleted by another transaction. This value will be honored when possible for isolation levels of *CS and *ALL.

***DFT**

Specifies that the concurrent access option will not be explicitly set for this program. The value that is in effect when the program is invoked will be used.

DATFMT

Specifies the format used when accessing date result columns. All output date fields are returned in the specified format. For input date strings, the specified value is used to determine whether the date is specified in a valid format.

Note: An input date string that uses the format *USA, *ISO, *EUR, or *JIS is always valid.

***JOB:**

The format specified for the job is used. Use the Display Job (DSPJOB) command to determine the current date format for the job.

***ISO**

The International Organization for Standardization (ISO) date format (yyyy-mm-dd) is used.

***EUR**

The European date format (dd.mm.yyyy) is used.

***USA**

The United States date format (mm/dd/yyyy) is used.

***JIS**

The Japanese Industrial Standard date format (yyyy-mm-dd) is used.

***MDY**

The date format (mm/dd/yy) is used.

***DMY**

The date format (dd/mm/yy) is used.

***YMD**

The date format (yy/mm/dd) is used.

***JUL**

The Julian date format (yyddd) is used.

DATSEP

Specifies the separator used when accessing date result columns.

Note: This parameter applies only when *JOB, *MDY, *DMY, *YMD, or *JUL is specified on the DATFMT parameter.

***JOB**

The date separator specified for the job is used. Use the Display Job (DSPJOB) command to determine the current value for the job.

***SLASH or '/'**

A slash (/) is used.

***PERIOD or '.'**

A period (.) is used.

***COMMA or ','**

A comma (,) is used.

***DASH or '-'**

A dash (-) is used.

***BLANK or ''**

A blank () is used.

DBGVIEW

Specifies whether the object can be debugged by the system debug facilities and the type of debug information to be provided by the compiler. The DBGVIEW parameter can only be specified in the body of SQL functions, procedures, and triggers.

If DEBUG MODE in a CREATE PROCEDURE or ALTER PROCEDURE statement is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

The possible choices are:

***NONE**

A debug view will not be generated.

***SOURCE**

Allows the compiled module object to be debugged using SQL statement source. If *SOURCE is specified, the modified source is stored in source file QSQDSRC in the same schema as the created function, procedure, or trigger.

***STMT**

Allows the compiled module object to be debugged using program statement numbers and symbolic identifiers.

***LIST**

Generates the listing view for debugging the compiled module object.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the procedure cannot be debugged by the Unified Debugger, but can be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

DECFLTRND

Specifies the DECFLOAT rounding mode used for static SQL statements. The possible choices are:

***CEILING**

Round toward +Infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

***DOWN**

Round toward zero (truncation). The discarded digits are ignored.

***FLOOR**

Round toward -Infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of the discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by one.

***HALFDOWN**

Round to nearest; if equidistant, round down. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

***HALFEVEN**

Round to nearest; if equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise (they represent exactly half), the result coefficient is unaltered if its rightmost digit is even or incremented by one (rounded up) if its rightmost digit is odd (to make an even digit).

***HALFUP**

Round to nearest; if equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

***UP**

Round away from zero. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

DECMP

Specifies the symbol that you want to represent the decimal point. The possible choices are:

***PERIOD**

The representation for the decimal point is a period.

***COMMA**

The representation for the decimal point is a comma.

***SYSVAL**

The representation for the decimal point is the system value (QDECDFMT).

***JOB**

The representation for the decimal point is the job value (DEC FMT).

DECRESULT

Specifies the maximum precision, maximum scale, and minimum divide scale that should be used during decimal operations, such as decimal arithmetic. The specified limits only apply to NUMERIC and DECIMAL data types.

max-precision

An integer constant that is the maximum precision that should be returned from decimal operations. The value can be 31 or 63. The default is 31.

max-scale

An integer constant that is the maximum scale that should be returned from decimal operations. The value can range from 0 to the maximum precision. The default is 31.

min-divide-scale

An integer constant that is the minimum scale that should be returned from division operations. The value can range from 1 to 9 and cannot be greater than *max-scale*. The default is 0, where 0 indicates that no minimum scale is specified.

DFTRDBCOL

Specifies the schema name used for the unqualified names of tables, views, indexes, and SQL packages. This parameter applies only to static SQL statements. This option will be ignored in REXX.

***NONE**

The naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option will be used.

schema-name

Specify the name of the schema. This value is used instead of the naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option.

DLYPRP

Specifies whether the dynamic statement validation for a PREPARE statement is delayed until an OPEN, EXECUTE, or DESCRIBE statement is run. Delaying validation improves performance by eliminating redundant validation. This option will be ignored in REXX.

***NO**

Dynamic statement validation is not delayed. When the dynamic statement is prepared, the access plan is validated. When the dynamic statement is used in an OPEN or EXECUTE statement, the access plan is revalidated. Because the authority or the existence of objects referred to by the dynamic statement may change, you must still check the SQLCODE or SQLSTATE after issuing the OPEN or EXECUTE statement to ensure that the dynamic statement is still valid.

***YES**

Dynamic statement validation is delayed until the dynamic statement is used in an OPEN, EXECUTE, or DESCRIBE SQL statement. When the dynamic statement is used, the validation is completed and an access plan is built. If you specify *YES, you should check the SQLCODE and SQLSTATE after running an OPEN, EXECUTE, or DESCRIBE statement to ensure that the dynamic statement is valid.

Note: If you specify *YES, performance is not improved if the INTO clause is used on the PREPARE statement or if a DESCRIBE statement uses the dynamic statement before an OPEN is issued for the statement.

DYNDFTCOL

Specifies the schema name specified for the DFTRDBCOL parameter is also used for dynamic statements. This option will be ignored in REXX.

***NO**

Do not use the value specified for DFTRDBCOL for unqualified names of tables, views, indexes, and SQL packages for dynamic SQL statements. The naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option will be used.

***YES**

The schema name specified for DFTRDBC0L will be used for the unqualified names of the tables, views, indexes, and SQL packages in dynamic SQL statements.

DYNUSRPRF

Specifies the user profile to be used for dynamic SQL statements. This option will be ignored in REXX.

***USER**

Local dynamic SQL statements are run under the user profile of the job. Distributed dynamic SQL statements are run under the user profile of the application server job.

***OWNER**

Local dynamic SQL statements are run under the user profile of the program's owner. Distributed dynamic SQL statements are run under the user profile of the SQL package's owner.

EVENTF

Specifies whether an event file will be generated. CoOperative Development Environment/400 (CODE/400) uses the event file to provide error feedback integrated with the CODE/400 editor.

***YES**

The compiler produces an event file for use by CoOperative Development Environment/400 (CODE/400).

***NO**

The compiler will not produce an event file for use by CoOperative Development Environment/400 (CODE/400).

EXTIND

Specifies how to treat indicator variable values passed for SQL statements.

***NO**

Specifies that extended indicator variables are not enabled and non-updatable columns are not allowed in the implicit or explicit UPDATE clause of a *select-statement*.

***YES**

Specifies that extended indicator variables are enabled and non-updatable columns are allowed in the implicit or explicit UPDATE clause of a *select-statement*.

INCFILE

Specifies the name of the source file to use for INCLUDE SQL statements. It will be used to locate any source member listed in an INCLUDE SQL statement when a source file name is not specified in the INCLUDE SQL statement.

This option is only allowed in an SQL function, SQL procedure, or SQL trigger. This option will be ignored in REXX.

file-name

Specify the name of the source file to be used. The name of the file can be qualified by one of the following library values:

***LIBL**

All libraries in the user and system portions of the job's library list are searched until the first match is found.

***CURLIB**

The current library for the job is searched. If no library is specified as the current library for the job, the QGPL library is used.

library-name

Specifies the name of the library to be searched.

LANGID

Specifies the language identifier to be used when SRTSEQ(*LANGIDUNQ) or SRTSEQ(*LANGIDSHR) is specified.

***JOB or *JOBRUN**

The LANGID value for the job is used.

For distributed applications, LANGID(*JOBRUN) is valid only when SRTSEQ(*JOBRUN) is also specified.

language-id

Specify a language identifier to be used. For information about the values that can be used for the language identifier, see the [Language identifier topic](#) in the Globalization topic collection.

MONITOR

Specifies whether the statements should be identified as user or system statements when a database monitor is run.

***USER**

The SQL statements are identified as user statements. This is the default.

***SYSTEM**

The SQL statements are identified as system statements.

NAMING

Specifies whether the SQL naming convention or the system naming convention is to be used. This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

The possible choices are:

***SYS**

The system naming convention will be used.

***SQL**

The SQL naming convention will be used.

OPTLOB

Specifies whether accesses to XML and LOBs can be optimized when accessing through DRDA. The possible choices are:

***YES**

LOB and XML accesses should be optimized. The first FETCH for a cursor determines how the cursor will be used for LOBs and XML on all subsequent FETCHes. This option remains in effect until the cursor is closed.

If the first FETCH uses a locator to access a LOB or XML column, no subsequent FETCH for that cursor can fetch that LOB or XML column into a LOB or XML variable.

If the first FETCH places the LOB or XML column into a LOB or XML variable, no subsequent FETCH for that cursor can use a locator for that column.

***NO**

LOB accesses should not be optimized. There is no restriction on whether a column is retrieved into a LOB locator or into a LOB variable. This option can cause performance to degrade.

OUTPUT

Specifies whether the precompiler and compiler listings are generated. The OUTPUT parameter can only be specified in the body of SQL functions, procedures, and triggers. The possible choices are:

***NONE**

The precompiler and compiler listings are not generated.

***PRINT**

The precompiler and compiler listings are generated.

RDBCNNMTH

Specifies the semantics used for CONNECT statements. This option will be ignored in REXX.

***DUW**

CONNECT (Type 2) semantics are used to support distributed unit of work. Consecutive CONNECT statements to additional relational databases do not result in disconnection of previous connections.

***RUW**

CONNECT (Type 1) semantics are used to support remote unit of work. Consecutive CONNECT statements result in the previous connection being disconnected before a new connection is established.

SQLCA

Specifies whether the fields in an SQLCA will be set after each SQL statement. The SQLCA option is only allowed for ILE C, ILE C++, ILE COBOL, and ILE RPG. This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

The possible choices are:

***YES**

The fields in an SQLCA will be set after each SQL statement. The user program can reference all the values in the SQLCA following the execution of an SQL statement.

***NO**

The fields in an SQLCA will not be set after each SQL statement. The user program should use the GET DIAGNOSTICS statement to retrieve information about the execution of the SQL statement.

SQLCA(*NO) will typically perform better than SQLCA(*YES).

In other host languages, an SQLCA is required and fields in the SQLCA will be set after each SQL statement.

SQLCURRULE

Specifies the semantics used for SQL statements.

***DB2**

The semantics of all SQL statements will default to the rules established for Db2. The following semantics are controlled by this option:

- Hexadecimal constants are treated as character data.
- Unicode graphic-string constants are UCS-2 (CCSID 13488).
- Assignments to SQL-variables and SQL-parameters within the body of a routine or a trigger will use retrieval assignment rules.
- When describing a select statement into an SQLDA and SQLN is smaller than the required number of SQLVAR entries, SQLSTATE 01005 is returned only when the result table contains LOBs or UDTs.

***STD**

The semantics of all SQL statements will default to the rules established by the ISO and ANSI SQL standards. The following semantics are controlled by this option:

- Hexadecimal constants are treated as binary data.
- Unicode graphic-string constants are UTF-16 (CCSID 1200).
- Assignments to SQL-variables and SQL-parameters within the body of a routine or a trigger will use storage assignment rules.
- When describing a select statement into an SQLDA and SQLN is smaller than the required number of SQLVAR entries, SQLSTATE 01005 is always returned.

SQLPATH

Specifies the path to be used to find procedures, functions, and user defined types in static SQL statements. This option will be ignored in REXX.

***LIBL**

The path used is the library list at runtime.

character-string

A character constant with one or more schema names that are separated by commas. Only system schema names can be specified.

SRTSEQ

Specifies the collating sequence table to be used for string comparisons in SQL statements.

Note: *HEX must be specified if a REXX procedure connects to an application server that is not a Db2 for i or a IBM i product whose release level is prior to V2R3M0.

***JOB or *JOBRUN**

The SRTSEQ value for the job is used.

***HEX**

A collating sequence table is not used. The hexadecimal values of the characters are used to determine the collating sequence.

***LANGIDUNQ**

The collating sequence table must contain a unique weight for each character in the code page.

***LANGIDSHR**

The shared-weight sort table for the LANGID specified is used.

srtseq-table-name

Specify the name of the collating sequence table to be used with this program. The name of the collating sequence table can be qualified by one of the following library values:

***LIBL**

All libraries in the user and system portions of the job's library list are searched until the first match is found.

***CURLIB**

The current library for the job is searched. If no library is specified as the current library for the job, the QGPL library is used.

library-name

Specify the name of the library to be searched.

SYSTIME

Specifies whether the CURRENT TEMPORAL SYSTEM_TIME special register affects static and dynamic SQL statements.

The possible choices are:

***YES**

Any references to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

***NO**

Any references to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

TGTRLS

Specifies the release of the operating system on which the user intends to use the object being created. The TGTRLS parameter can only be specified in the body of SQL functions, procedures, and triggers, or as part of an external function or external procedure create statement.

VxRxMx

Specify the release in the format VxRxMx, where Vx is the version, Rx is the release, and Mx is the modification level. For example, V7R1M0 is version 7, release 1, modification level 0. The object can be used on a system with the specified release or with any subsequent release of the operating system installed.

If you specify a release value which is earlier than the earliest release level currently supported by the operating system, the level will be upgraded to the current N-2 release value. No message will be issued.

TIMFMT

Specifies the format used when accessing time result columns. All output time fields are returned in the specified format. For input time strings, the specified value is used to determine whether the time is specified in a valid format.

Note: An input time string that uses the format *USA, *ISO, *EUR, or *JIS is always valid.

***HMS**

The (hh:mm:ss) format is used.

***ISO**

The International Organization for Standardization (ISO) time format (hh.mm.ss) is used.

***EUR**

The European time format (hh.mm.ss) is used.

***USA**

The United States time format (hh:mm xx) is used, where xx is AM or PM.

***JIS**

The Japanese Industrial Standard time format (hh:mm:ss) is used.

TIMSEP

Specifies the separator used when accessing time result columns.

Note: This parameter applies only when *HMS is specified on the TIMFMT parameter.

***JOB**

The time separator specified for the job is used. Use the Display Job (DSPJOB) command to determine the current value for the job.

***COLON or ':'**

A colon (:) is used.

***PERIOD or '.'**

A period (.) is used.

***COMMA or ','**

A comma (,) is used.

***BLANK or ''**

A blank () is used.

USRPRF

Specifies the user profile that is used when the compiled program object is run, including the authority that the program object has for each object in static SQL statements. The profile of either the program owner or the program user is used to control which objects can be used by the program object. This option will be ignored in REXX.

***NAMING**

The user profile is determined by the naming convention. If the naming convention is *SQL, USRPRF(*OWNER) is used. If the naming convention is *SYS, USRPRF(*USER) is used.

***USER**

The profile of the user running the program object is used.

***OWNER**

The user profiles of both the program owner and the program user are used when the program is run.

Notes

Default values: The default values for the options depend on the language, object type, and the options in effect at create time:

- When an SQL procedure, SQL function, or SQL trigger is created, the default values for the options are those in effect at the time the object is created. For example, if an SQL procedure is created and the

current COMMIT option is *CS, *CS is the default COMMIT option. Each option is then updated as it is encountered within the SET OPTION statement.

- For application programs other than REXX, the default values for the options are specified on the CRTSQLxxx command. Each option is then updated as it is encountered within a SET OPTION statement. All SET OPTION statements must precede any other embedded SQL statements.
- At the start of a REXX procedure the options are set to their default value. The default value for each option is the first value listed in the syntax diagram. When an option is changed by a SET OPTION statement, the new value will stay in effect until the option is changed again or the REXX procedure ends.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- *UR can be used as a synonym for *CHG.
- *NC can be used as a synonym for *NONE.
- *RS can be used as a synonym for *ALL.

Examples

Example 1: Set the isolation level to *ALL and the naming mode to SQL names.

```
EXEC SQL SET OPTION COMMIT =*ALL, NAMING =*SQL
```

Example 2: Set the date format to European, the isolation level to *CS, and the decimal point to the comma.

```
EXEC SQL SET OPTION DATFMT = *EUR, COMMIT = *CS, DECMPT = *COMMA
```

SET PATH

The SET PATH statement changes the value of the CURRENT PATH special register.

Invocation

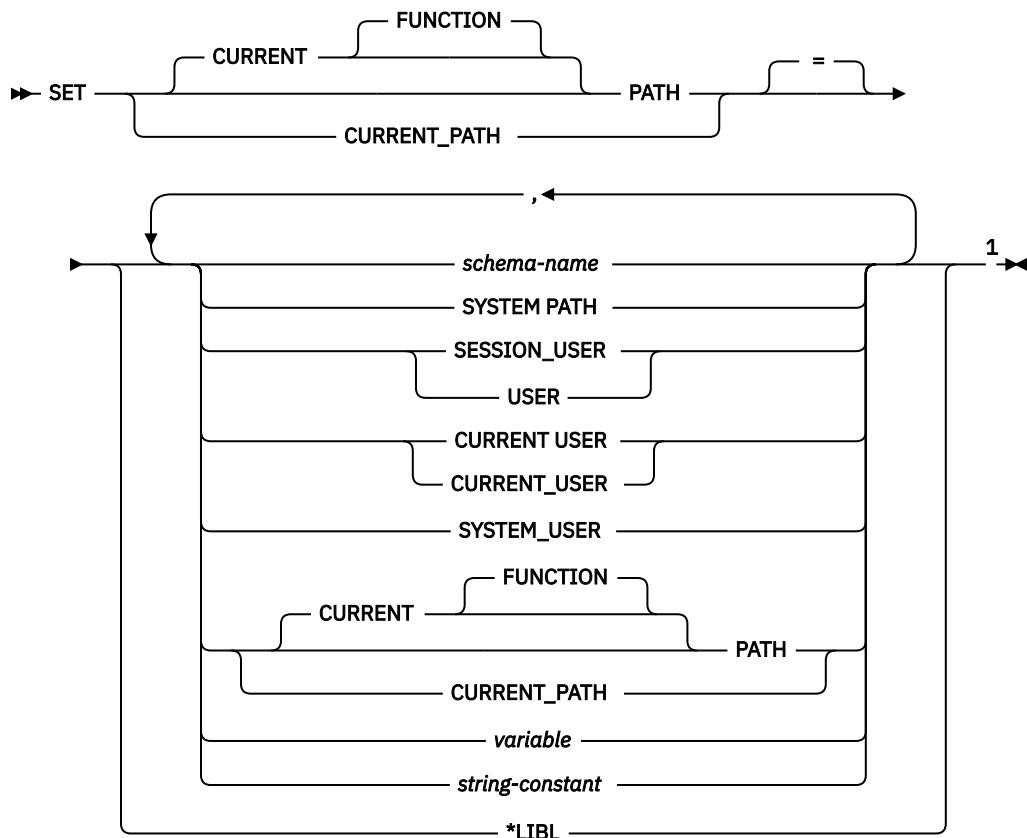

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Notes:

¹ SYSTEM PATH, SESSION_USER, USER, CURRENT_USER, SYSTEM_USER, and CURRENT PATH may each be specified at most once on the right side of the statement.

Description

schema-name

Identifies a schema. If a specified schema name is a system schema name, no validation that the schema exists is made at the time the PATH is set. For example, if a *schema-name* is misspelled, it could affect the way subsequent SQL operates. If the specified schema name is not a system schema name, the schema must exist at the time the PATH is set.

Although not recommended, PATH can be specified as a *schema-name* if it is specified as "PATH".

SYSTEM PATH

Specifies the schema names for the system path. This value is the same as specifying the schema names "QSYS","QSYS2","SYSPROC","SYSIBMADM".

SESSION_USER or USER

Specifies the value of the SESSION_USER special register.

CURRENT USER

Specifies the value of the CURRENT USER special register.

SYSTEM_USER

Specifies the value of the SYSTEM_USER special register.

CURRENT PATH

Specifies the value of the CURRENT PATH special register before the execution of this statement. CURRENT PATH is not allowed if the current path is *LIBL.

variable

Specifies a variable that contains one or more schema names that are separated by commas. It can be a global variable if it is qualified with schema name.

The variable:

- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the *variable* must not exceed the maximum length of a path.
- Must not be followed by an indicator variable.
- Must not be the null value.
- Each schema name must conform to the rules for forming an ordinary or delimited identifier.
- Each schema name must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.
- Must be padded on the right with blanks if the variable is fixed length character.
- If the SET statement is specified in an SQL routine, SQL trigger, or compound statement, *variable* cannot be a global variable with an unqualified name.

string-constant

A character constant with one or more schema names that are separated by commas.

The string constant:

- Each schema name must conform to the rules for forming an ordinary or delimited identifier.
- Each schema name must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

***LIBL**

The path is set to the library list of the current thread.

Notes

Transaction considerations: The SET PATH statement is not a committable operation. ROLLBACK has no effect on the CURRENT PATH.

Rules for the content of the SQL path:

- A schema name must not appear more than once in the path.
- The number of schemas that can be specified is limited by the total length of the CURRENT PATH special register. The special register string is built by taking each schema name specified and removing trailing blanks, delimiting with double quotes, and separating each schema name by a comma. An error is returned if the length of the resulting string exceeds 3483 bytes. A maximum of 268 schema names can be represented in the path.
- There is a difference between specifying a single keyword (such as USER, or PATH, or CURRENT_PATH) as a single keyword, or as a delimited identifier. To indicate that the current value of a special register specified as a single keyword should be used in the SQL path, specify the name of the special register as a keyword. If the name of the special register is specified as a delimited identifier instead (for example, "USER"), it is interpreted as a schema name of that value ('USER'). For example, assuming that the current value of the USER special register is SMITH, then SET PATH = SYSIBM, USER, "USER" results in a CURRENT PATH value of "SYSIBM","SMITH","USER".
- The following rules are used to determine whether a value specified in a SET PATH statement is a variable or a *schema-name*:
 - If *name* is the same as a parameter or SQL variable in the SQL procedure, *name* is interpreted as a parameter or SQL variable, and the value in *name* is assigned to PATH.
 - If *name* is not the same as a parameter or SQL variable in the SQL procedure, *name* is interpreted as *schema-name*, and the value *name* is assigned to PATH.

The system path: SYSTEM PATH refers to the system path for a platform. The schemas QSYS, QSYS2, SYSPROC, and SYSIBADM do not need to be specified. If not included in the path, they are implicitly

assumed as the last schemas (in this case, they are not included in the value shown for the CURRENT PATH special register).

The initial value of the CURRENT PATH special register is *LIBL if system naming was used for the first SQL statement run in the activation group. The initial value is "QSYS","QSYS2","SYSPROC","SYSIBMADM","X" (where X is the value of the USER special register) if SQL naming was used for the first SQL statement.

Using the SQL path: The CURRENT PATH special register is used to resolve user-defined types, functions, and procedures in dynamic SQL statements. For more information see “[SQL path](#)” on page 54.

Example

The following statement sets the CURRENT PATH special register.

```
SET PATH = FERMAT, "McDuff", SYSIBM
```

The following statement retrieves the current value of the SQL path special register into the host variable called CURPATH.

```
EXEC SQL VALUES (CURRENT PATH) INTO :CURPATH;
```

The value would be "FERMAT","McDuff","SYSIBM" if set by the previous example.

SET RESULT SETS

The SET RESULT SETS statement specifies the result sets that can be returned from a procedure.

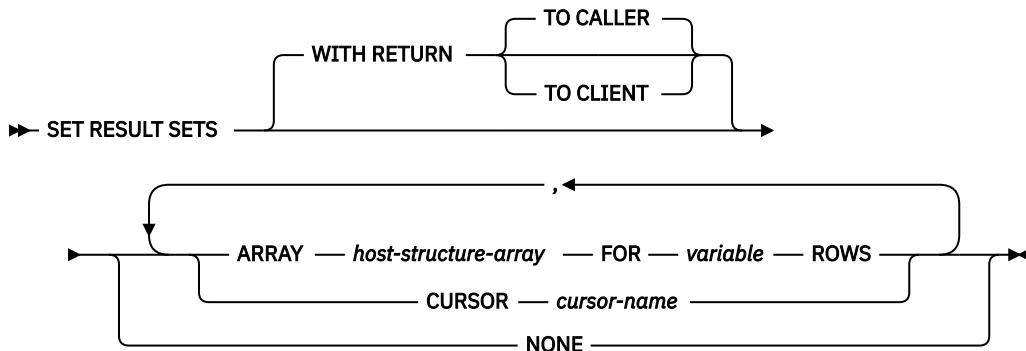

Invocation

This statement can only be embedded in an application program or SQL procedure. It is an executable statement that cannot be dynamically prepared. It is not allowed in a Java or REXX procedure.

Authorization

None required.

Syntax

Description

WITH RETURN

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

TO CALLER

Specifies that the cursor can return a result set to the caller of the procedure. For example, if the caller is a client application, the result set is returned to the client application.

TO CLIENT

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger called the procedure either directly or indirectly, result sets cannot be returned to the client and the cursor will be closed after the procedure finishes.

CURSOR *cursor-name*

Identifies a cursor to be used to define a result set that can be returned from a procedure. The *cursor-name* must identify a declared cursor as explained in “[Description](#)” on page 1039 for the DECLARE CURSOR statement. When the SET RESULT SETS statement is executed, the cursor must be in the open state. It cannot be an allocated cursor.

ARRAY *host-structure-array*

host-structure-array identifies an array of host structures defined in accordance with the rules for declaring host structures. The array cannot contain a C NUL-terminated host variable.

The first structure in the array corresponds to the first row of the result set, the second structure in the array corresponds to the second row of the result set, and so on. In addition, the first value in the row corresponds to the first item in the structure, the second value in the row corresponds to the second item in the structure, and so on.

LOBs and XML cannot be returned in an array when using DRDA.

Only one array can be specified in a SET RESULT SETS statement, including any RETURN TO CLIENT array result sets from nested calls to procedures.

FOR *variable* ROWS

Specifies the number of rows in the result set. The *variable* must be a numeric variable with zero scale, and it must not include an indicator variable. It must not be a global variable. The number of rows specified must be less than or equal to the dimension of the host structure array.

NONE

Specifies that no result sets will be returned. Cursors left open when the procedure ends will not be returned.

Notes

For more information about result sets, see [Result sets from procedures and WITH RETURN clause](#).

External procedures: There are three ways to return result sets from an external procedure:

- If a SET RESULT SETS statement is executed in the procedure, the SET RESULT SETS statement identifies the result sets. The result sets are returned in the order specified on the SET RESULT SETS statement.
- If a SET RESULT SETS statement is not executed in the procedure,
 - If no cursors have specified a WITH RETURN clause, each cursor that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.
 - If any cursors have specified a WITH RETURN clause, each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

The RESULT SETS clause should be specified on the ALTER PROCEDURE (external), CREATE PROCEDURE (external) statement, or DECLARE PROCEDURE statement to return result sets from a procedure. The maximum number of result sets returned cannot be larger than the number specified on the ALTER PROCEDURE (external), CREATE PROCEDURE (external) statement, or DECLARE PROCEDURE statement.

SQL procedures: In order to return result sets from an SQL procedure, the procedure must be created with the RESULT SETS clause. Each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set.

- If a SET RESULT SETS statement is executed in the procedure, the SET RESULT SETS statement identifies which of these result sets to return. The result sets are returned in the order specified on the SET RESULT SETS statement.
- If a SET RESULT SETS statement is not executed in the procedure the result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

The RESULT SETS clause must be specified on the CREATE PROCEDURE (SQL) statement to return any result sets from an SQL procedure. The maximum number of result sets returned cannot be larger than the number specified on the CREATE PROCEDURE statement.

Example

The following SET RESULT SETS statement specifies cursor X as the result set that will be returned when the procedure is called. For more information and complete examples showing the use of result sets from ODBC clients, see the [IBM i Access Family](#) topic collection.

```
EXEC SQL SET RESULT SETS CURSOR X;
```

SET SCHEMA

The SET SCHEMA statement changes the value of the CURRENT SCHEMA special register.

Invocation

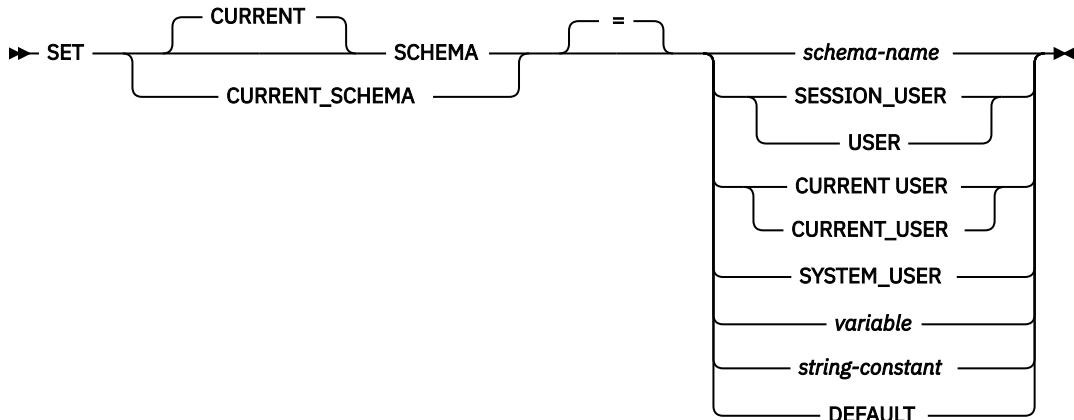

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

schema-name

Identifies a schema. If the specified schema name is a system schema name, no validation that the schema exists is made at the time the current schema is set. If the specified schema name is not a system schema name, the schema must exist at the time the current schema is set.

If the value specified does not conform to the rules for a *schema-name*, an error is returned.

SESSION_USER or USER

This value is the SESSION_USER special register.

CURRENT_USER

Specifies the value of the CURRENT_USER special register.

SYSTEM_USER

This value is the SYSTEM_USER special register.

variable

Specifies a variable which contains a schema name. It can be a global variable if it is qualified with schema name. The content is not folded to uppercase.

The variable:

- Must be a character-string or Unicode graphic variable. The actual length of the contents of the *variable* after trimming any trailing blanks must not exceed the length of a schema name. See Appendix A, “SQL limits,” on page 1413.
- Must not be followed by an indicator variable.
- Must not be the null value.
- Must conform to the rules for forming an ordinary or delimited identifier.
- Must be padded on the right with blanks if the variable is fixed length.
- Must not be the keyword SESSION_USER, CURRENT_USER, SYSTEM_USER, or USER.
- If the SET statement is specified in an SQL routine, SQL trigger, or compound statement, *variable* cannot be a global variable with an unqualified name.

string-constant

A character constant with a schema name.

The string constant:

- Must have a length after trimming any trailing blanks that does not exceed the maximum length of a schema name
- Must include a schema name that is left justified and conforms to the rules for forming an ordinary or delimited identifier.

- Must not be the keyword SESSION_USER, CURRENT_USER, SYSTEM_USER, or USER.

DEFAULT

The CURRENT SCHEMA is set to its initial value. The initial value for SQL naming is USER. The initial value for system naming is *LIBL.

Notes

Considerations for keywords: There is a difference between specifying a single keyword (such as USER) as a single keyword or as a delimited identifier. To indicate that the current value of the USER special register should be used for setting the current schema, specify USER as a keyword. If USER is specified as a delimited identifier instead (for example, "USER"), it is interpreted as a schema name of that value ("USER").

Transaction considerations: The SET SCHEMA statement is not a committable operation. ROLLBACK has no effect on the CURRENT SCHEMA.

Impact on other special registers: Setting the CURRENT SCHEMA special register does not affect the CURRENT PATH special register. Hence, the CURRENT SCHEMA will not be included in the SQL path and functions, procedures and user-defined type resolution may not find these objects. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.

CURRENT SCHEMA: The value of the CURRENT SCHEMA special register is used as the qualifier for some unqualified names in all dynamic SQL statements except in programs where the DYNDFTCOL has been specified. If DYNDFTCOL is specified in a program, its schema name is used instead of the CURRENT SCHEMA schema name. For information about qualification of names, see “[Qualification of unqualified object names](#)” on page 55.

For SQL naming, the initial value of the CURRENT SCHEMA special register is equivalent to USER. For system naming, the initial value of the CURRENT SCHEMA special register is *LIBL’.

Syntax alternatives: CURRENT SQLID is accepted as a synonym for CURRENT SCHEMA and the effect of a SET CURRENT SQLID statement will be identical to that of a SET CURRENT SCHEMA statement. No other effects, such as statement authorization changes, will occur.

SET SCHEMA is equivalent to calling the QSQCHGDC API.

Examples

Example 1: The following statement sets the CURRENT SCHEMA special register.

```
SET SCHEMA = RICK
```

Example 2: The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.

```
EXEC SQL VALUES(CURRENT SCHEMA) INTO :CURSCHEMA
```

The value would be RICK, set by the previous example.

SET SESSION AUTHORIZATION

The SET SESSION AUTHORIZATION statement changes the value of the SESSION_USER and USER special registers. It also changes the name of the user profile associated with the current thread.

Invocation

This statement can be embedded within an application program or issued interactively. It is an executable statement that can be dynamically prepared. It must not be specified in REXX.

SET SESSION AUTHORIZATION is not allowed in an SQL trigger, SQL function, or SQL procedure.

Authorization

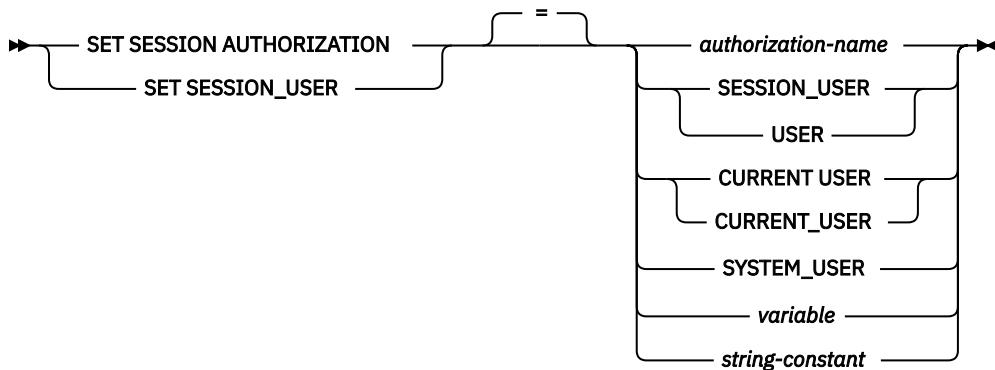

If the authorization name specified on the statement is different than the value in the SYSTEM_USER special register, the privileges held by the authorization ID of the statement must include the system authority of *ALLOBJ.

No authorization is required to execute this statement if the authorization name specified on the statement is the same as the SYSTEM_USER special register.

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Description

authorization-name

Identifies an authorization ID that is to be used as the new value for the SESSION_USER special register and the runtime authorization ID.

The authorization ID must be a valid user profile or group user profile that exists at the current server. Several system user profiles that do not have a user profile handle may not be used. For more information, see the Get Profile Handle API.

CURRENT USER

The SESSION_USER special register and the runtime authorization ID are set to the CURRENT USER special register.

SESSION_USER or USER

The SESSION_USER special register and the runtime authorization ID are set to the USER special register.

SYSTEM_USER

The SESSION_USER special register and the runtime authorization ID are set to the SYSTEM_USER special register.

variable

A variable which contains an authorization ID name. It can be a global variable if it is qualified with schema name.

The variable:

- Must be a character-string variable.

- If *variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value.
- Must include an authorization ID that is left justified and must conform to the rules for forming an ordinary or delimited identifier.
- Must be padded on the right with blanks.
- Must not be the null value.
- Must not be the keyword USER, SESSION_USER, SYSTEM_USER, or CURRENT_USER.

string-constant

A character constant with an authorization ID.

Notes

Other effects of SET SESSION AUTHORIZATION: SET SESSION AUTHORIZATION causes the following to occur:

- All cursors that were opened during the unit of work are closed.
- All LOB locators are freed.
- All locks acquired under this unit of work's commitment definition are released.
- All prepared statements are destroyed.
- All SQL descriptor areas are deallocated.
- All procedure result sets are cleared.
- The encryption password is reset.
- All open native database files and Integrated File System (IFS) files are closed, including sockets, NTC sessions, and memory maps.

Other resources are preserved when SET SESSION AUTHORIZATION is executed, including global variables and declared temporary tables. It is recommended that all declared temporary tables be dropped or cleared and global variables be cleared before executing the SET SESSION AUTHORIZATION statement.

SET SESSION AUTHORIZATION restrictions: This statement can only be issued as the first statement that results in work that might be backed out during the unit of work. The following executable statements may be issued prior to executing SET SESSION AUTHORIZATION:

- All SQL transaction statements
- All SQL connection statements
- All SQL session statements
- GET DIAGNOSTICS

SET SESSION AUTHORIZATION is not allowed if any connections other than the connection to the current server exist, including any local connections to a non-default activation group.

SET SESSION AUTHORIZATION is not allowed if any held cursors are open or any held locators exist.

SET SESSION AUTHORIZATION scope: The scope of the SET SESSION AUTHORIZATION is the current thread. Other threads in the application process are unaffected.

Examples

Example 1: The following statement sets the SESSION_USER special register.

```
SET SESSION_USER = RAJIV
```

Example 2: Set the session authorization ID (the SESSION_USER special register) to be the value of the system authorization ID, which is the ID that established the connection on which the statement has been issued.

SET TRANSACTION

The SET TRANSACTION statement sets the isolation level, read only attribute, or diagnostics area size for the current unit of work.

Invocation

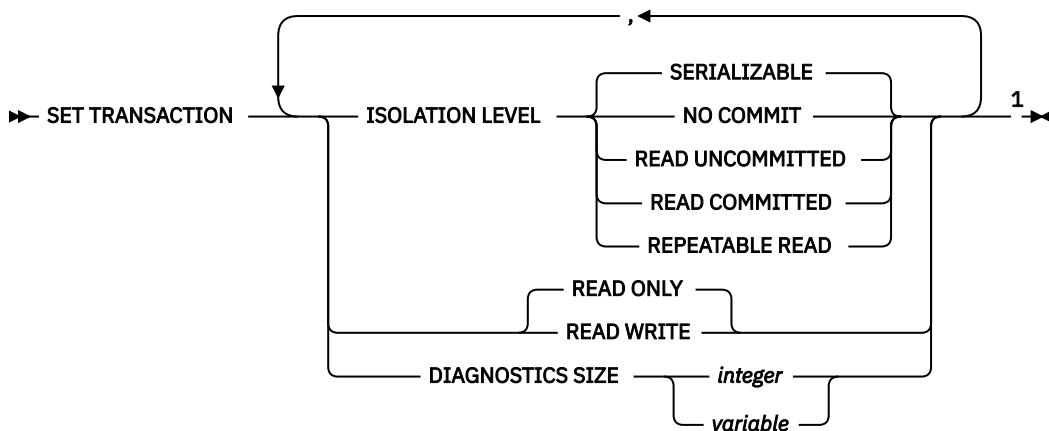

This statement can be embedded within an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The USAGE privilege on the schema containing the global variable
- Database administrator authority

Syntax

Notes:

- ¹ Only one ISOLATION LEVEL clause, one READ WRITE or READ ONLY clause, and one DIAGNOSTICS SIZE clause may be specified.

Description

ISOLATION LEVEL

Specifies the isolation level of the transaction. If the ISOLATION LEVEL clause is not specified, ISOLATION LEVEL SERIALIZABLE is implicit

NO COMMIT

Specifies isolation level NC (COMMIT(*NONE)).

READ UNCOMMITTED

Specifies isolation level UR (COMMIT(*CHG)).

READ COMMITTED

Specifies isolation level CS (COMMIT(*CS)).

REPEATABLE READ

Specifies isolation level RS (COMMIT(*ALL)).

SERIALIZABLE

Specifies isolation level RR (COMMIT(*RR)).

READ WRITE or READ ONLY

Specifies whether the transaction allows data change operations.

READ WRITE

Specifies that all SQL operations are allowed. This is the default unless ISOLATION LEVEL READ UNCOMMITTED is specified.

READ ONLY

Specifies that only SQL operations that do not change SQL data are allowed. If ISOLATION LEVEL READ UNCOMMITTED is specified, this is the default.

DIAGNOSTICS SIZE

Specifies the maximum number of GET DIAGNOSTICS condition areas for the current transaction.

The GET DIAGNOSTICS *statement-information-item* MORE will be set to 'Y' for the current statement if the statement exceeds the maximum number of condition areas for the current transaction. The maximum size of the diagnostics area is 90K. The specified maximum number of condition areas must be between 1 and 32767.

integer

An integer constant that specifies the maximum number of condition areas for the current transaction.

variable

Identifies a variable which contains the maximum number of condition areas for the current transaction. The variable must be a numeric variable with a zero scale and must not be followed by an indicator variable.

Notes

Scope of SET TRANSACTION: The SET TRANSACTION statement sets the isolation level for SQL statements for the current activation group of the process. If that activation group has commitment control scoped to the job, then the SET TRANSACTION statement sets the isolation level of all other activation groups with job commit scoping as well.

If an isolation clause is specified in an SQL statement, that isolation level overrides the transaction isolation level and is used for dynamic SQL statements.

The scope of the SET TRANSACTION statement is based on the context in which it is run. If the SET TRANSACTION statement is run in a trigger, the isolation level specified applies to all subsequent SQL statements until another SET TRANSACTION statement occurs or until the trigger completes, whichever happens first. If the SET TRANSACTION statement is run outside a trigger, the isolation level specified applies to all subsequent SQL statements (except those statements within a trigger that are executed after a SET TRANSACTION statement in the trigger) until a COMMIT or ROLLBACK operation occurs.

For more information about isolation levels, see ["Isolation level"](#) on page 23.

SET TRANSACTION restrictions: The SET TRANSACTION statement can only be executed when it is the first SQL statement in a unit of work, unless:

- all previous statements executed in the unit of work are SET TRANSACTION statements or statements that are executed under isolation level NC, or
- it is executed in a trigger.

In a trigger, SET TRANSACTION with READ ONLY is allowed only on a COMMIT boundary. The SET TRANSACTION statement can be executed in a trigger at any time, but it is recommended that it be executed as the first statement in the trigger. The SET TRANSACTION statement is useful within triggers to set the isolation level for SQL statements in the trigger to the same level as the application which caused the trigger to be activated.

A SET TRANSACTION statement is not allowed if the current connection is to a remote application server unless it is in a trigger at the current server. Once a SET TRANSACTION statement is executed, CONNECT and SET CONNECTION statements are not allowed until the unit of work is committed or rolled back.

SET TRANSACTION is not allowed as the first statement in a secondary thread.

The SET TRANSACTION statement has no effect on WITH HOLD cursors that are still open when the SET TRANSACTION statement is executed.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords NC or NONE can be used as synonyms for NO COMMIT.
- The keywords UR and CHG can be used as synonyms for READ UNCOMMITTED.
- The keyword CS can be used as a synonym for READ COMMITTED.
- The keywords RS or ALL can be used as synonyms for REPEATABLE READ.
- The keyword RR can be used as a synonym for SERIALIZABLE.

Examples

Example 1: The following SET TRANSACTION statement sets the isolation level to NONE (equivalent to specifying *NONE on the SQL precompiler command).

```
EXEC SQL SET TRANSACTION ISOLATION LEVEL NO COMMIT;
```

Example 2: The following SET TRANSACTION statement sets the isolation level to SERIALIZABLE.

```
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE
```

SET variable

The SET variable statement produces a result table consisting of at most one row and assigns the values in that row to variables.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared if the all variables being set are global variables. It must not be specified in REXX.

Authorization

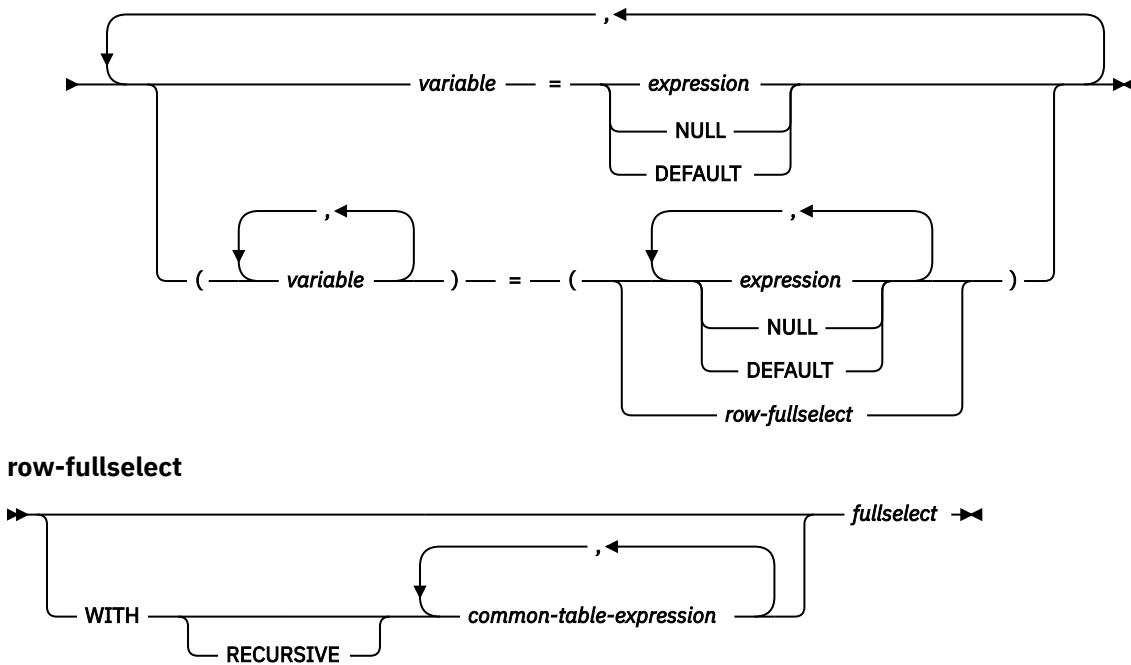

If a *row-fullselect* is specified, see “[fullselect](#)” on page 638 for an explanation of the authorization required for each subselect.

If a global variable is specified on the left hand side of the assignment, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

Syntax

►► SET ►►

Description

variable, ...

Identifies one or more variables or host structures that must be declared in accordance with the rules for declaring variables (see “[References to host variables](#)” on page 130). A host structure is logically replaced by a list of variables that represent each of the elements of the host structure.

The value to be assigned to each *variable* can be specified immediately following the *variable*, for example, *variable* = *expression*, *variable* = *expression*. Or, sets of parentheses can be used to specify all the *variables* and then all the values, for example, (*variable*, *variable*) = (*expression*, *expression*).

The data type of each variable must be compatible with its corresponding result column. Each assignment is made according to the rules described in “[Assignments and comparisons](#)” on page 83. The number of *variables* specified to the left of the equal operator must equal the number of values in the corresponding result specified to the right of the equal operator. If the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

If an error occurs as the result of an arithmetic expression in the *expression* or SELECT list of the subselect (division by zero, or overflow) or a character conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, a warning is returned.) If you do not provide an indicator variable, an error is returned. It is possible that some values have already been assigned to variables and will remain assigned when the error occurs.

expression

Specifies the new value of the variable. The *expression* is any expression of the type described in “[Expressions](#)” on page 147. It must not include a column name.

NULL

Specifies that the new value for the variable is the null value.

DEFAULT

Specifies that the new value for the variable is its initial default value. DEFAULT can only be assigned to a global variable. Only one variable can be assigned in the SET statement when DEFAULT is used.

row-fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding *variable*. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

WITH common-table-expression

Specifies a common table expression. For an explanation of common table expression, see “[common-table-expression](#)” on page 643.

fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding *variable*. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

Notes

Variable assignment: If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result is returned in the indicator variable associated with the variable, if an indicator variable is provided.

If the specified variable is a C NUL-terminated variable and is not large enough to contain the result and the NUL-terminator:

- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
 - The result is truncated.
 - The last character is the NUL-terminator.
 - The value 'W' is assigned to SQLWARN1 in the SQLCA.
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
 - The NUL-terminator is not returned.
 - The value 'N' is assigned to SQLWARN1 in the SQLCA.

Multiple assignments: If more than one assignment is included in the same SET statement, all *expressions* and *row-fullselects* are completely evaluated before the assignments are performed. Thus, references to a target variable in an *expression* or *row-fullselect* are always the value of the target variable prior to any assignment in the SET statement.

Examples

Example 1: Assign the value of the CURRENT PATH special register to host variable HV1.

```
EXEC SQL SET :HV1 = CURRENT PATH;
```

Example 2: Assume that LOB locator LOB1 is associated with a CLOB value. Assign a portion of the CLOB value to host variable DETAILS using the LOB locator.

```
EXEC SQL SET :DETAILS = SUBSTR(:LOB1,1,35);
```

SIGNAL

The SIGNAL statement signals an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE and optional *condition-information-items*.

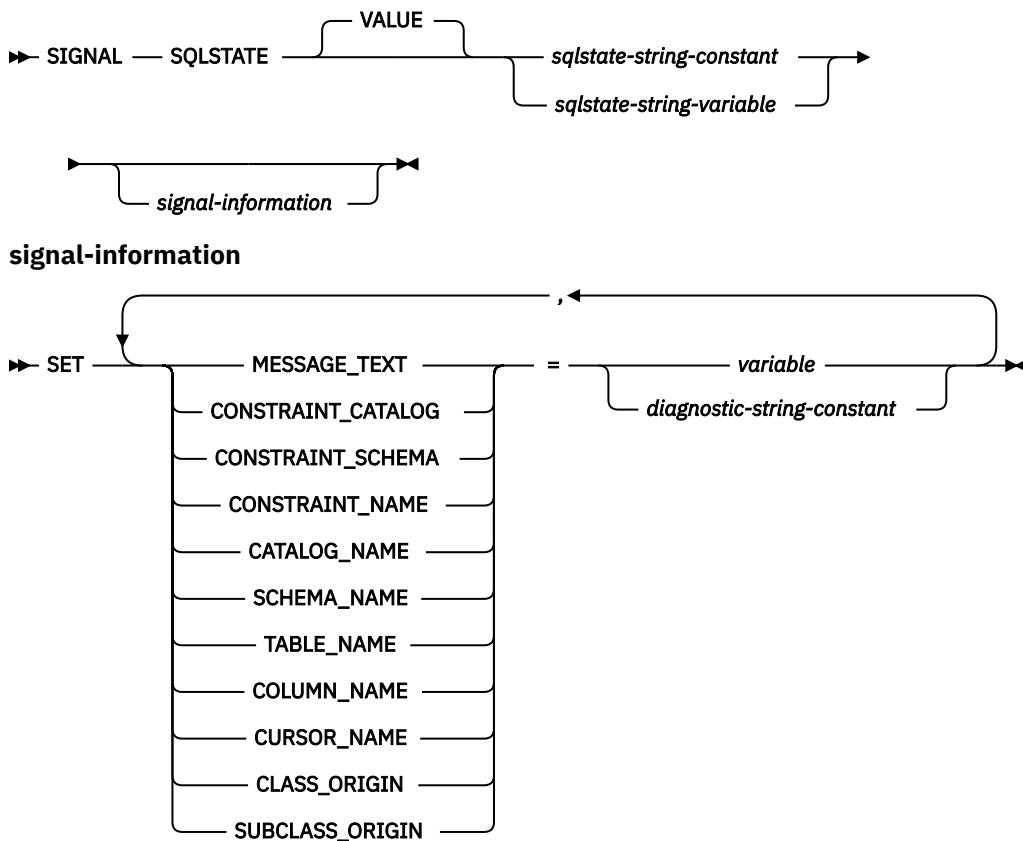

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

SQLSTATE VALUE

Specifies the SQLSTATE that will be signaled. The specified value must not be null and must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

sqlstate-string-constant

The *sqlstate-string-constant* must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The *sqlstate-string-variable* must be a character or Unicode graphic variable. It cannot be a global variable. The actual length of the contents of the *variable* must be 5.

SET

Introduces the assignment of values to *condition-information-items*. The *condition-information-item* values can be accessed using the GET DIAGNOSTICS statement. The only *condition-information-item* that can be accessed in the SQLCA is MESSAGE_TEXT.

MESSAGE_TEXT

Specifies a string that describes the error or warning.

If an SQLCA is used,

- the string is returned in the SQLERRMC field of the SQLCA
- if the actual length of the string is longer than 1000 bytes, it is truncated without a warning.

CONSTRAINT_CATALOG

Specifies a string that indicates the name of the database that contains a constraint related to the signaled error or warning.

CONSTRAINT_SCHEMA

Specifies a string that indicates the name of the schema that contains a constraint related to the signaled error or warning.

CONSTRAINT_NAME

Specifies a string that indicates the name of a constraint related to the signaled error or warning.

CATALOG_NAME

Specifies a string that indicates the name of the database that contains a table or view related to the signaled error or warning.

SCHEMA_NAME

Specifies a string that indicates the name of the schema that contains a table or view related to the signaled error or warning.

TABLE_NAME

Specifies a string that indicates the name of a table or view related to the signaled error or warning.

COLUMN_NAME

Specifies a string that indicates the name of a column in the table or view related to the signaled error or warning.

CURSOR_NAME

Specifies a string that indicates the name of a cursor related to the signaled error or warning.

CLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE class related to the signaled error or warning.

SUBCLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE subclass related to the signaled error or warning.

variable

Identifies a variable that must be declared in accordance with the rules for declaring variables (see “[References to host variables](#)” on page 130). The variable contains the value to be assigned to the *condition-information-item*. The variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. It cannot be a global variable.

diagnostic-string-constant

Specifies a character string constant that contains the value to be assigned to the *condition-information-item*.

Notes

SQLSTATE values: Any valid SQLSTATE value can be used in the SIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

SQLSTATE values are comprised of a two-character class code value, followed by a three-character subclass code value. Class code values represent classes of successful and unsuccessful execution conditions.

- SQLSTATE classes that begin with the characters '7' through '9' or 'I' through 'Z' may be defined. Within these classes, any subclass may be defined.
- SQLSTATE classes that begin with the characters '0' through '6' or 'A' through 'H' are reserved for the database manager. Within these classes, subclasses that begin with the characters '0' through 'H' are reserved for the database manager. Subclasses that begin with the characters 'I' through 'Z' may be defined.

For more information about SQLSTATEs, see the [SQL Messages and Codes](#) topic collection.

Assignment: When the SIGNAL statement is executed, the value of each of the specified *string-constants* and *variables* is assigned to the corresponding *condition-information-item*. However, if the length of a *string-constant* or *variable* is longer than the maximum length of the corresponding *condition-information-item*, it is truncated without a warning. For details on the assignment rules, see [“Assignments and comparisons” on page 83](#). For details on the maximum length of specific *condition-information-items*, see [“GET DIAGNOSTICS” on page 1144](#).

Processing a SIGNAL statement: When a SIGNAL statement is issued, the SQLCODE is based on the SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not found is signaled and the SQLCODE is set to +438.
- Otherwise, an exception is signaled and the SQLCODE is set to -438.

Examples

Example 1: Signal SQLSTATE '75002' with a descriptive message text.

```
EXEC SQL SIGNAL SQLSTATE '75002'  
      SET MESSAGE_TEXT = 'Customer number is not known';
```

Example 2: Signal SQLSTATE '75002' with a descriptive message text and associate a specific table with the error.

```
EXEC SQL SIGNAL SQLSTATE '75002'  
      SET MESSAGE_TEXT = 'Customer number is not known',  
      SCHEMA_NAME = 'CORPDATA',  
      TABLE_NAME = 'CUSTOMER';
```

TAG

The TAG statement identifies the branch location for a WHENEVER statement in ILE RPG. The statement can be used to define a *host-label* instead of defining the label directly with an RPG TAG operation.

Invocation

This statement can only be embedded in an ILE RPG application program. It is not an executable statement.

Authorization

None required.

Syntax

►► TAG — *host-label* ►►

Description

host-label

Specifies the label to use for generating an ILE RPG TAG operation. This is intended to identify the next executable statement for the GOTO clause of a WHENEVER statement.

Note

SQL does not verify the position of the TAG statement or the uniqueness or value of *host-label*. The ILE RPG compiler must allow a TAG operation at the SQL TAG statement's location.

Example

In a free-form ILE RPG program, continue processing at HANDLER for an SQL statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR GOTO HANDLER;
...
EXEC SQL TAG HANDLER;
```

TRANSFER OWNERSHIP

The TRANSFER OWNERSHIP statement transfers ownership of a database object.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

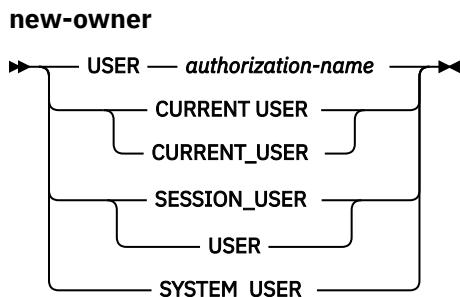

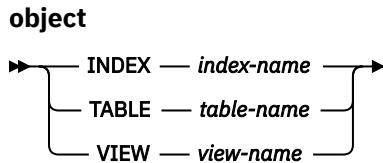

To transfer ownership for a table, view, or index, the authorization ID of the statement must be the owner of the object and the privileges held must include at least one of the following:

- The following system authorities:
 - The system authorities of *OBJOPR and *OBJEXIST on the object to be transferred
 - The USAGE privilege on the schema that contains the object to be transferred
- Database administrator authority
- Security administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

►► TRANSFER OWNERSHIP OF **object** TO **new-owner** {
 REVOKE PRIVILEGES
 PRESERVE PRIVILEGES
} ►►

Description

INDEX *index-name*

Identifies the index that is to have its ownership transferred. The *index-name* must identify an index that exists at the current server.

TABLE *table-name*

Identifies the table that is to have its ownership transferred. The *table-name* must identify a base table that exists at the current server, but must not identify a declared global temporary table or a catalog table.

VIEW *view-name*

Identifies the view that is to have its ownership transferred. The *view-name* must identify a view that exists at the current server, but must not identify a catalog view.

USER *authorization-name*

Specifies the authorization ID to which ownership of the object is being transferred.

CURRENT USER or CURRENT_USER

Specifies that the value of the CURRENT USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

SESSION_USER or USER

Specifies that the value of the SESSION_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

SYSTEM_USER

Specifies that the value of the SYSTEM_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

REVOKE PRIVILEGES or PRESERVE PRIVILEGES

Specifies the privileges of the current owner of the object after the ownership is transferred.

REVOKE PRIVILEGES

Specifies that the current owner will not have any explicit privileges to the object after the transfer is complete.

PRESERVE PRIVILEGES

Specifies that the current owner of an object that is to have its ownership transferred will continue to hold any existing privileges on the object after the transfer. For example, any privileges that were granted to the creator of a view continue to be held by the original owner even after ownership has been transferred to another user.

Rules

Ownership of most system-defined objects cannot be transferred.

Ownership of objects in a schema whose name starts with 'SYS' or 'Q' cannot be transferred.

An authorization ID that has security administrator authority cannot transfer ownership of an object to itself, if it is not already the owner of the object.

Notes

- All privileges that the current owner has on the object are transferred to the new owner.
- When the ownership of a database object is transferred, the new owner will not necessarily have privileges for the object's dependencies.
- If an attempt is made to transfer ownership of an object to its owner, a warning is returned.

Examples

Example 1: Transfer ownership of table T1 to PAUL.

```
TRANSFER OWNERSHIP OF TABLE WALID.T1  
TO USER PAUL PRESERVE PRIVILEGES
```

Paul becomes the owner of table WALID.T1 and is granted all the privileges that the previous owner of the table had. The prior owner retains all privileges as well.

Example 2: Transfer ownership of view V1 to HENRY and remove privileges from the previous owner

```
TRANSFER OWNERSHIP OF VIEW V1  
TO USER HENRY
```

Henry becomes the owner of view V1 and is granted all the privileges that the previous owner of the view had. The prior owner no longer has any explicit privileges on the view.

TRUNCATE

The TRUNCATE statement deletes all of the rows from a table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement:
 - The DELETE privilege on the table, and
 - The USAGE privilege on the schema containing the table.
- Database administrator authority

If the IGNORE DELETE TRIGGERS option is specified, the privileges held by the authorization ID of the statement must include the following:

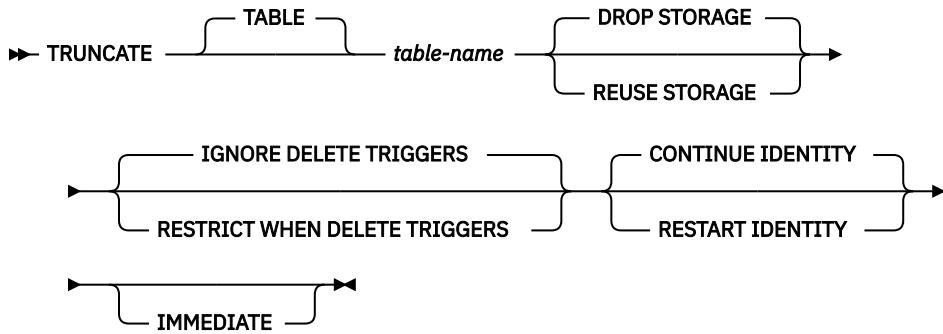

- The ALTER privilege on the table and the system authority of *OBJOPR on the table.

If row access control or column access control is activated for the table, the privileges held by the authorization ID of the statement must include the following:

- The system authorities of *OBJOPR and *OBJEXIST on the table.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

Description

table-name

Identifies the table from which rows are to be deleted. The name must identify a table that exists at the current server. It must not identify a catalog table, a view, or a system-period temporal table.

DROP STORAGE or REUSE STORAGE

Specifies whether to drop or reuse the existing storage that is allocated for the table.

DROP STORAGE

All storage allocated for the table is released and made available. This is the default.

REUSE STORAGE

All storage allocated for the table will continue to be allocated for the table, but the storage will be considered empty.

IGNORE DELETE TRIGGERS or RESTRICT WHEN DELETE TRIGGERS

Specifies what to do when delete triggers are defined on the table.

IGNORE DELETE TRIGGERS

Specifies that any delete triggers that are defined for the table are not activated by the truncation operation. This is the default.

RESTRICT WHEN DELETE TRIGGERS

Specifies that an error is returned if delete triggers are defined on the table.

CONTINUE IDENTITY or RESTART IDENTITY

Specifies how to handle generation of identity column values.

CONTINUE IDENTITY

If an identity column exists for the table, the next identity column value generated continues with the next value that would have been generated if the TRUNCATE statement had not been executed. This is the default.

RESTART IDENTITY

If an identity column exists for the table, the next identity column value generated is the initial value that was specified when the identity column was defined.

IMMEDIATE

Specifies that the truncate operation is processed immediately and cannot be undone.

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

The truncate operation cannot be performed if any session has a cursor open on the table or holds a lock on the table.

If IMMEDIATE is not specified, a ROLLBACK statement can undo the truncate operation.

Notes

Referential Integrity: The identified table cannot be a parent table in a referential constraint.

Number of rows deleted: The ROW_COUNT condition area item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA) is set to -1 for the truncate operation. The total number of rows that were deleted from the table is not returned.

If no rows exist in the table, a SQLSTATE value of '02000' is returned.

For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#).

Examples

Example 1: Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```
TRUNCATE TABLE INVENTORY  
DROP STORAGE  
IGNORE DELETE TRIGGERS;
```

Example 2: Empty an unused inventory table regardless of any existing triggers but preserve its allocated space for later reuse.

```
TRUNCATE TABLE INVENTORY  
REUSE STORAGE  
IGNORE DELETE TRIGGERS;
```

Example 3: Empty an unused inventory table permanently (a ROLLBACK statement cannot undo the truncate operation when the IMMEDIATE option is specified) regardless of any existing triggers and preserve its allocated space for reuse.

```
TRUNCATE TABLE INVENTORY  
REUSE STORAGE  
IGNORE DELETE TRIGGERS  
IMMEDIATE;
```

UPDATE

The UPDATE statement updates the values of specified columns in rows of a table or view. Updating a row of a view updates a row of its base table, if no INSTEAD OF UPDATE trigger is defined on this view. If such a trigger is defined, the trigger will be activated instead.

There are two forms of this statement:

- The *Searched* UPDATE form is used to update one or more rows (optionally determined by a search condition).
- The *Positioned* UPDATE form is used to update exactly one row (as determined by the current position of a cursor).

Invocation

A Searched UPDATE statement can be embedded in an application program or issued interactively. A Positioned UPDATE must be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table or view identified in the statement:
 - The UPDATE privilege on the table or view, or

- The UPDATE privilege on each column to be updated; and
- The USAGE privilege on the schema containing the table or view
- Database administrator authority

If the *expression* in the *assignment-clause* contains a reference to a column of the table or view, or if the *search-condition* in a Searched UPDATE contains a reference to a column of the table or view, the privileges held by the authorization ID of the statement must also include one of the following¹³¹:

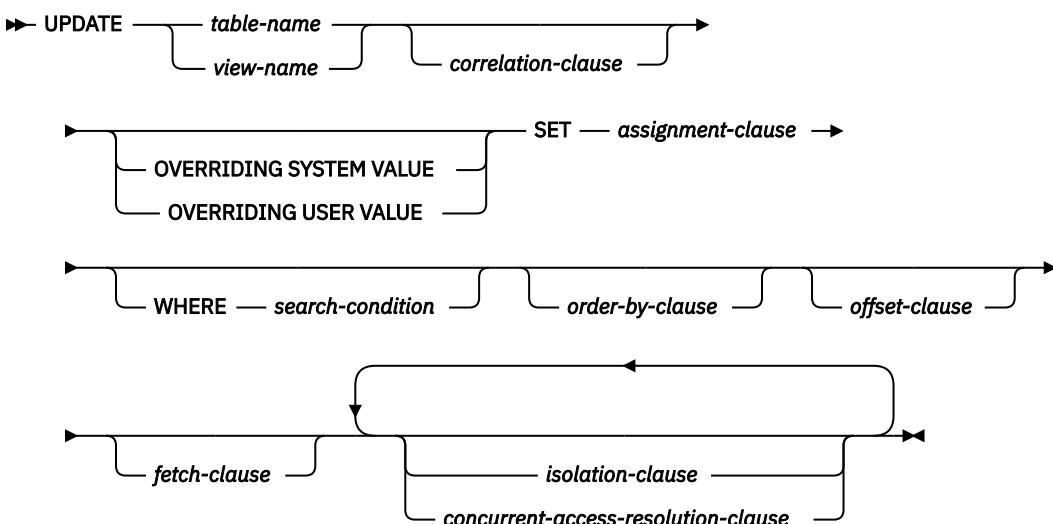

- The SELECT privilege on the table or view
- Database administrator authority

If the *search-condition* includes a subquery or if the *assignment-clause* includes a *scalar-fullselect* or *row-fullselect*, see [Chapter 6, “Queries,” on page 597](#) for an explanation of the authorization required for each subselect.

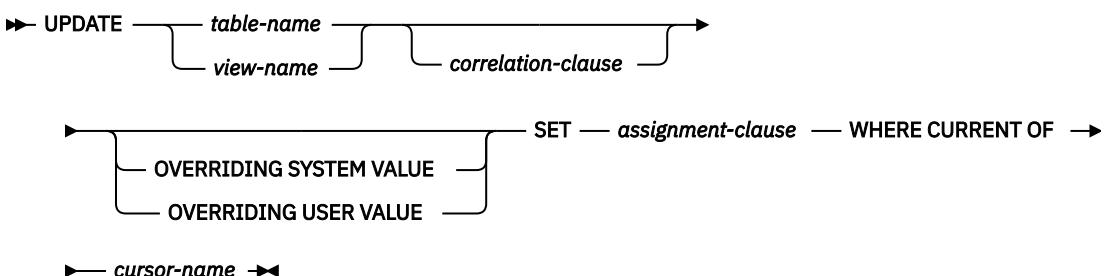

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

Searched UPDATE:

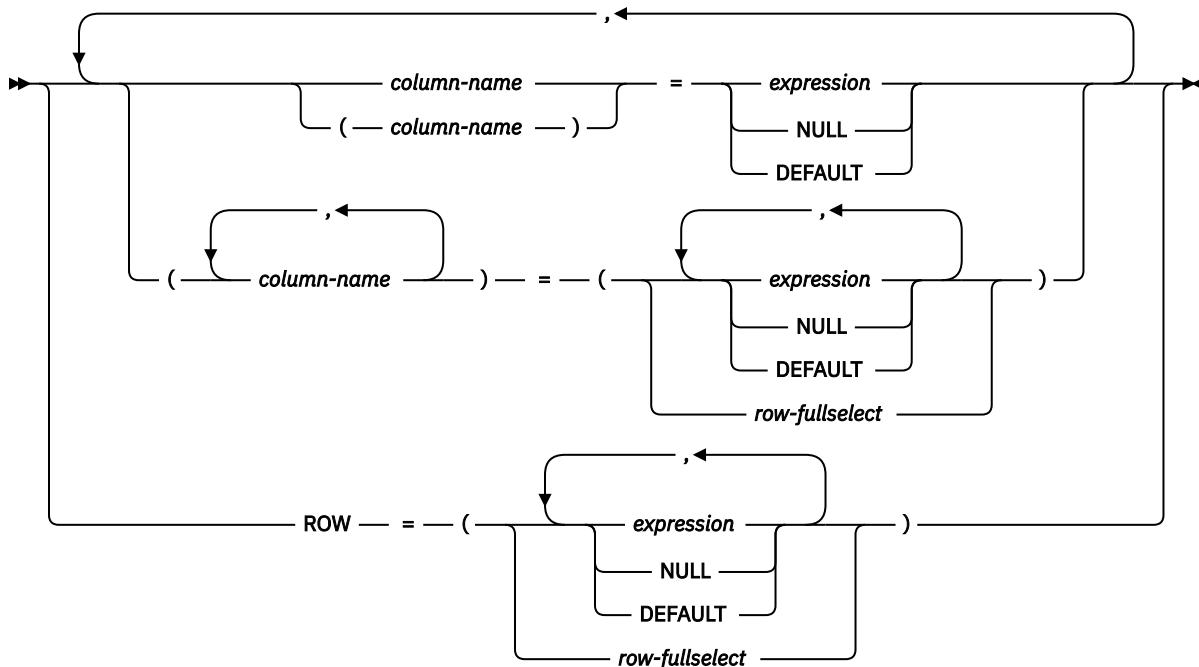

Positioned UPDATE:

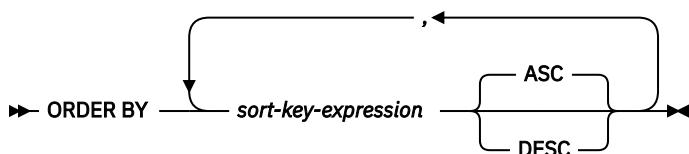

assignment-clause

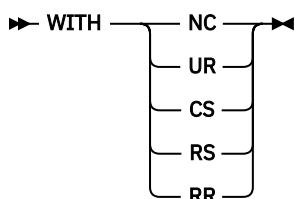

¹³¹ Many *assignment-clauses* and *search-conditions* that do not reference a column of the table or view have this same requirement.

order-by-clause

isolation-clause

Description

table-name* or *view-name

To Name or New Name
Identifies the table or view to be updated. The name must identify a table or view that exists at the current server, but it must not identify a history table, a catalog table, a view of a catalog table, or a read-only view. For an explanation of read-only views and updatable views, see [“CREATE VIEW”](#) on page 1029.

correlation-clause

Can be used within *search-condition* or *assignment-clause* to designate the table or view. For an explanation of *correlation-clause*, see “[table-reference](#)” on page 603. For an explanation of *correlation-name*, see “[Correlation names](#)” on page 123.

OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE

OVERRIDING SYSTEM VALUE OR OVERRIDING USER VALUE
Specifies whether system-generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns in the SET clause must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns in the SET clause must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

OVERRIDING SYSTEM VALUE

Specifies that the value specified in the SET clause for a ROWID, identity, or row change timestamp column that is defined as GENERATED ALWAYS is used. A system-generated value is not used.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

OVERRIDING USER VALUE

Specifies that the value specified in the SET clause for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is used, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE is specified:

- A value cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.
- A value can be specified for a ROWID column that is defined as GENERATED BY DEFAULT. If a value is specified, that value is assigned to the column. However, a value in a ROWID column defined BY DEFAULT can be updated only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i.
- A value can be specified for an identity or row change timestamp column that is defined as GENERATED BY DEFAULT. When a value of an identity column or row change timestamp column defined BY DEFAULT is updated, the database manager does not verify that the specified value is a unique value for the column unless the identity column or row change timestamp column is the sole key in a unique constraint or unique index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

SET

Introduces the assignment of values to column names.

assignment-clause

column-name

Identifies a column to be updated. The *column-name* must identify a column of the specified table or view. If extended indicators are not enabled, that column must be an updatable column. A column must not be specified more than once.

For a Positioned UPDATE:

- If the UPDATE clause was specified in the SELECT statement of the cursor, each column name in the SET list must also appear in the UPDATE clause.
- If the UPDATE clause was not specified in the SELECT statement of the cursor, the name of any updatable column may be specified.

For more information, see “[update-clause](#)” on page 649.

A view column derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same UPDATE statement.

If a list of *column-names* is specified, the number of *expressions*, NULLs, and DEFAULTS must match the number of *column-names*.

ROW

Identifies all the columns of the specified table or view except for columns defined with the hidden attribute. If a view is specified, none of the columns of the view may be derived from a scalar function, constant, or expression.

The number of *expressions*, NULLs, and DEFAULTs (or the number of result columns from a *row-fullselect*) must match the number of columns in the row.

For a Positioned UPDATE, if the UPDATE clause was specified in the SELECT statement of the cursor, each column of the table or view must also appear in the UPDATE clause. For more information, see “[update-clause](#)” on page 649.

ROW may not be specified for a view that contains a view column derived from the same column as another column of the view, because both columns cannot be updated in the same UPDATE statement.

expression

Specifies the new value of the column. The *expression* is any expression of the type described in “[Expressions](#)” on page 147. It must not include an aggregate function.

A *column-name* in an expression must name a column of the named table or view. For each row updated, the value of the column in the expression is the value of the column in the row before the row is updated.

Each variable in the clause must identify a host structure or variable that is declared in accordance with the rules for declaring host structures and variables. In the operational form of the statement, a reference to a host structure is replaced by a reference to each of its variables.

If *expression* is a single host variable, the host variable can include an indicator with an extended indicator value. If extended indicators are enabled and an expression in the assignment clause is not a single host variable, the extended indicator values of DEFAULT and UNASSIGNED must not be used. For further information about variables and structures, see “[References to host variables](#)” on page 130 and “[Host structures](#)” on page 135. If a host structure is specified, the keyword ROW must be specified.

NULL

Specifies the new value for a column is the null value. NULL should only be specified for nullable columns.

DEFAULT

Specifies that the default value is assigned to a column. The value that is used depends on how the column was defined, as follows:

- If the column is defined as a generated column based on an expression, the column value will be generated by the database manager, based on the expression.
- If the column is a ROWID, identity column, row-begin column, row-end column, or transaction-start-ID column, the database manager will generate a new value.
- If the WITH DEFAULT clause is used, the default used is as defined for the column (see *default-clause* in *column-definition* in “[CREATE TABLE](#)” on page 945).
- If the WITH DEFAULT clause or the NOT NULL clause is not used, the value used is NULL.
- If the column is defined as a row change timestamp column, a new row change timestamp value is assigned to the column.

If the NOT NULL clause is used and the WITH DEFAULT clause is not used, or if DEFAULT NULL is used, the DEFAULT keyword cannot be specified for that column.

DEFAULT must be specified for an identity column defined as GENERATED ALWAYS unless OVERRIDING SYSTEM VALUE is used.

The only value that a row-begin, row-end, transaction-start-ID, or generated expression column can be set to is DEFAULT.

row-fullselect

A fullselect that returns a single result row. The number of result columns in the select list must match the number of *column-names* (or if ROW is specified, the number of columns in the row) specified for assignment. The result column values are assigned to each corresponding *column-name*. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

The *row-fullselect* may contain references to columns of the target table of the UPDATE statement. For each row updated, the value of such a column in the expression is the value of the column in the row before the row is updated.

WHERE

Specifies the rows to be updated. The clause can be omitted, or a *search-condition* or *cursor-name* can be specified. If the clause is omitted, all rows of the table or view are updated.

search-condition

Is any search described in “[Search conditions](#)” on page 208. Each *column-name* in the search condition, other than in a subquery, must name a column of the table or view. When the search condition includes a subquery in which the same table is the base object of both the UPDATE and the subquery, the subquery is completely evaluated before any rows are updated.

The *search-condition* is applied to each row of the table or view. The updated rows are those for which the results of the *search-condition* are true.

If the *search-condition* contains a subquery, the subquery can be thought of as being executed each time the *search-condition* is applied to a row, and the results of that subquery used in applying the *search-condition*. In actuality, a subquery with no correlated references may be executed only once. A subquery with a correlated reference may have to be executed once for each row.

CURRENT OF cursor-name

Identifies the cursor to be used in the update operation. The *cursor-name* must identify a declared cursor as explained in “[DECLARE CURSOR](#)” on page 1037.

The table or view named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must not be read-only. For an explanation of read-only result tables, see “[DECLARE CURSOR](#)” on page 1037.

The DECLARE CURSOR statement must not have a period-specification for the table or view used by the update statement.

When the UPDATE statement is executed, the cursor must be positioned on a row; that row is updated.

order-by-clause

Specifies the order of the rows for application of the *offset-clause* and *fetch-clause*. An *order-by-clause* should be specified to ensure a predictable order for determining the set of rows to be updated based on the *offset-clause* and *fetch-clause*.

sort-key-expression

An expression that specifies the value that is to be used to order the rows that qualify for the update operation. If a single *sort-key-expression* is identified, the rows are ordered by the values of that *sort-key-expression*. If more than one *sort-key-expression* is identified, the rows are ordered by the values of the first *sort-key-expression*, then by the values of the second *sort-key-expression*, and so on.

The result of the *sort-key-expression* must not be DATALINK or XML.

ASC

Uses the values of the *sort-key-expression* in ascending order. This is the default.

DESC

Uses the values of the *sort-key-expression* in descending order.

Ordering is performed in accordance with the comparison rules described in [Chapter 2, “Language elements,”](#) on page 43. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key-expression* have an arbitrary order. If you do not specify ORDER BY, the rows to be updated have an arbitrary order.

offset-clause

Limits the effect of the update by skipping a subset of the qualifying rows. For more information on the *offset-clause*, see “[offset-clause](#)” on page 634.

fetch-clause

Limits the effect of the update to a subset of the qualifying rows. For more information on the *fetch-clause*, see “[fetch-clause](#)” on page 635.

isolation-clause

Specifies the isolation level to be used for this statement.

WITH

Introduces the isolation level, which may be one of:

- *RR* Repeatable read
- *RS* Read stability
- *CS* Cursor stability
- *UR* Uncommitted read
- *NC* No commit

If *isolation-clause* is not specified the default isolation is used. See “[isolation-clause](#)” on page 650 for a description of how the default is determined.

concurrent-access-resolution-clause

Specifies the concurrent access resolution to use for the select statement. For more information, see “[concurrent-access-resolution-clause](#)” on page 651.

UPDATE Rules

Assignment: Update values are assigned to columns in accordance with the storage assignment rules described in “[Assignments and comparisons](#)” on page 83.

Validity: Updates must obey the following rules. If they do not, or if any other errors occur during the execution of the UPDATE statement, no rows are updated.

- *Fullselects:* The *row-fullselect* or *scalar-fullselect* shall return no more than one row (SQLSTATE 21000).
- *Unique constraints and unique indexes:* If the identified table, or the base table of the identified view, has one or more unique indexes or unique constraints, each row update in the table must conform to the limitations imposed by those indexes and constraints (SQLSTATE 23505).

All uniqueness checks are effectively made at the end of the statement. In the case of a multiple-row UPDATE statement of a column involved in a unique index or unique constraint, this would occur after all rows were updated.

- *Check constraints:* If the identified table, or the base table of the identified view, has one or more check constraints, each check constraint must be true or unknown for each row updated in the table (SQLSTATE 23513).

All check constraints are effectively validated at the end of the statement. In the case of a multiple-row UPDATE statement, this would occur after all rows were updated.

- *Views and the WITH CHECK OPTION:* If a view is identified, the updated rows must conform to any applicable WITH CHECK OPTION (SQLSTATE 44000). For more information, see “[CREATE VIEW](#)” on page 1029.

Triggers: If the identified table or the base table of the identified view has an update trigger, the trigger is activated. A trigger might cause other statements to be executed or raise error conditions based on the updated values.

Referential Integrity: The value of the parent key in a parent row must not be changed.

If the update values produce a foreign key that is nonnull, the foreign key must be equal to some value of the parent key of the parent table of the relationship.

The referential constraints (other than a referential constraint with a RESTRICT delete rule) are effectively checked at the end of the statement. In the case of a multiple-row UPDATE statement, this would occur after all rows were updated.

XML values: When an XML column is updated, the new value must be a well-formed XML document.

Updating rows in a table for which row or column access control is enforced: When an UPDATE statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be updated. Typically those rules are based on the authorization ID of the statement. The following describes how enabled row permissions and column masks are used during UPDATE:

- Row permissions are used to identify the set of rows to be updated.

When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID of the UPDATE statement. If the WHERE clause is specified in the UPDATE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be updated. If there is no WHERE clause, all the accessible rows are the rows to be updated.

- If there are rows to be updated, the following rules determine whether those rows can be updated:
 - When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for update and an error is returned.
 - If the rows are updatable, and there is a BEFORE UPDATE trigger for the table, the trigger is activated. Within the trigger actions, the new values for update might be modified in transition variables. When the final values are returned from the trigger, the new values are used for the update.
 - The rows that are to be updated must conform to the enabled row permissions:
For each row that is to be updated, the old values are replaced with the new values that were specified in the UPDATE statement. A row that conforms to the enabled row permissions is a row that, if updated, can be retrieved using the derived row access control search condition.
 - If the rows are updatable, and there is an AFTER UPDATE trigger for the table, the trigger is activated.

Masked data can be assigned to a variable used as a value for the update operation. If an update violation check constraint does not exist for the column, the masked data will be updated into the column and no error will be issued.

Updating a partitioning key of a partitioned table: If a partitioning key of a row of a partitioned table is updated such that the row belongs in a different partition:

- The specified target table must not be an alias that references a single partition of the table.
- The specified target table must be journaled.

Extended indicator usage: When extended indicators are enabled, indicator values other than positive values and 0 (zero) through -7 must not be specified. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts in which they are not supported.

Extended indicators: In the *assignment-clause* of an UPDATE statement, an expression that is a reference to a single host variable can result in assigning an extended indicator value. Specifying an indicator value with the extended indicator value of UNASSIGNED has the same effect as if the column had not been specified in the *assignment-clause*. Assigning an extended indicator value of DEFAULT assigns the default value to the column, and must only be specified for a column that is defined with a default value.

If a target column is not updatable, for example an identity column defined as GENERATED ALWAYS, it must be assigned the extended indicator variable value of UNASSIGNED, unless it is a generated column defined as GENERATED ALWAYS. If the target column is a generated column defined as GENERATED ALWAYS, then it must be assigned the extended indicator variable value of DEFAULT or UNASSIGNED.

An UPDATE statement must not specify the extended indicator value of UNASSIGNED for all target columns.

Extended indicators and update triggers: If the indicator value for a target column is UNASSIGNED, that column is not considered to have been updated.

Extended indicators and deferred error checks: When extended indicators are enabled, validation that would otherwise be done during statement preparation to recognize an update of a non-updatable column is deferred until the statement is executed.

Considerations for a system-period temporal table: When a row of a system-period temporal table is updated, the database manager updates the values of the row-begin and transaction-start-ID columns as follows:

- A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.
- A transaction start-ID column is assigned a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable and there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are updated within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

If the UPDATE statement has a search condition containing a correlated subquery that references historical rows (explicitly referencing the name of the history table name or implicitly through the use of a period specification in the FROM clause), the old version of the updated rows that are inserted as historical rows (into the history table if any) are potentially visible to update operations for the rows subsequently processed for the statement.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target (direct or indirect) of the UPDATE statement cannot be a system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the target of an UPDATE statement cannot be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing an invocation of an external routine with a data access indication other than NO SQL.

Considerations for a history table: When a row of a system-period temporal table is updated, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. The database manager assigns the value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for an end column in a history table across transactions. The timestamp value might be adjusted to ensure that rows inserted into the history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. Otherwise, an error is returned.

For an update operation, the adjustment only affects the value for the end column corresponding to the row-end column in the history table associated with the system-period temporal table. Take these

adjustments into consideration on subsequent references to the table whether there is a search for the transaction start time in the values for the columns corresponding to the row-begin and row-end columns of the period in the associated system-period temporal table.

Notes

Update operation errors: If an update value violates any constraints, or if any other error occurs during the execution of the UPDATE statement and COMMIT(*NONE) was not specified, all changes made during the execution of the statement are backed out. However, other changes in the unit of work made prior to the error are not backed out. If COMMIT(*NONE) is specified, changes are not backed out.

It is possible for an error to occur that makes the state of the cursor unpredictable.

Number of rows updated: When an UPDATE statement completes execution, the number of rows updated is returned in the ROW_COUNT statement information item in the SQL Diagnostics Area (and SQLERRD(3) in the SQLCA). For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#).

For a description of ROW_COUNT, see [“GET DIAGNOSTICS” on page 1144](#). For a description of the SQLCA, see [Appendix C, “SQLCA \(SQL communication area\),” on page 1431](#).

Locking: Unless appropriate locks already exist, one or more exclusive locks are acquired by the execution of a successful UPDATE statement. Until these locks are released by a commit or rollback operation, the updated rows can only be accessed by:

- The application process that performed the update.
- Another application process using COMMIT(*NONE) or COMMIT(*CHG) through a read-only operation

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the COMMIT, ROLLBACK, and LOCK TABLE statements, and isolation levels in [“Isolation level” on page 23](#). Also, see the [Database Programming topic collection](#).

A maximum of 500 000 000 rows can be updated or changed in any single UPDATE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) has been specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger.

Generated columns: System-generation of GENERATED ALWAYS values can be avoided through the use of the QSYS2.REPLICATION_OVERRIDE built-in global variable. When this global variable is used, the user-provided values are used to update all columns defined as GENERATED ALWAYS. See [“REPLICATION_OVERRIDE” on page 213](#) for details.

REXX: Variables cannot be used in the UPDATE statement within a REXX procedure. Instead, the UPDATE must be the object of a PREPARE and EXECUTE using parameter markers.

Datalinks: If the URL value of a DATALINK column is updated, this is the same as deleting the old DATALINK value then inserting the new one. First, if the old value was linked to a file, that file is unlinked. Then, unless the linkage attributes of the DATALINK value are empty, the specified file is linked to that column.

The comment value of a DATALINK column can be updated without relinking the file by specifying an empty string as the URL path (for example, as the data-location argument of the DLVALUE scalar function or by specifying the new value to be the same as the old value). If a DATALINK column is updated with a null, it is the same as deleting the existing DATALINK value.

An error may occur when attempting to update a DATALINK value if the file server of either the existing value or the new value is no longer registered with the database server.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
- The keyword ALL can be used as a synonym for RS.

Examples

Example 1: Change the job (JOB) of employee number (EMPNO) '000290' in the EMPLOYEE table to 'LABORER'.

```
UPDATE EMPLOYEE
  SET JOB = 'LABORER'
 WHERE EMPNO = '000290'
```

Example 2: Increase the project staffing (PRSTAFF) by 1.5 for all projects that department (DEPTNO) 'D21' is responsible for in the PROJECT table.

```
UPDATE PROJECT
  SET PRSTAFF = PRSTAFF + 1.5
 WHERE DEPTNO = 'D21'
```

Example 3: All the employees except the manager of department (WORKDEPT) 'E21' have been temporarily reassigned. Indicate this by changing their job (JOB) to NULL and their pay (SALARY, BONUS, COMM) values to zero in the EMPLOYEE table.

```
UPDATE EMPLOYEE
  SET JOB=NULL, SALARY=0, BONUS=0, COMM=0
 WHERE WORKDEPT = 'E21' AND JOB <> 'MANAGER'
```

Example 4: In a Java program display the rows from the EMPLOYEE table on the connection context 'ctx' and then, if requested to do so, change the job (JOB) of certain employees to the new job keyed in (NEWJOB).

```
#sql iterator empIterator implements sqlj.runtime.ForUpdate
  with( updateColumns='JOB' )
  ( ... );
empIterator C1;

#sql [ctx] C1 = { SELECT * FROM EMPLOYEE };

#sql { FETCH :C1 INTO ... };
while ( !C1.endFetch() ) {
  System.out.println( ... );

  if ( condition for updating row ) {
    #sql [ctx] { UPDATE EMPLOYEE
      SET JOB = :NEWJOB
      WHERE CURRENT OF :C1 };
  }

  #sql { FETCH :C1 INTO ... };
}
C1.close();
```

VALUES

The VALUES statement is a form of query. It can be embedded in an SQLJ application program or issued interactively.

For detailed information, see [“fullselect” on page 638](#).

VALUES INTO

The VALUES INTO statement produces a result table consisting of at most one row and assigns the values in that row to variables.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared, but cannot be issued interactively unless all variables being assigned are global variables. It must not be specified in REXX or Java.

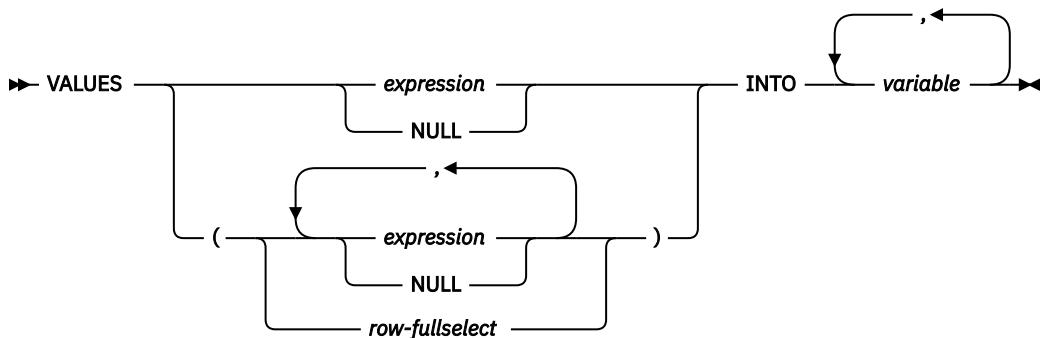

Authorization

If a *row-fullselect* is specified, see Chapter 6, “Queries,” on page 597 for an explanation of the authorization required for each subselect.

If a global variable is specified on the right hand side of the assignment, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

Syntax

Description

VALUES

Introduces a single row consisting of one or more columns.

expression

Specifies the new value of the variable. The *expression* is any expression of the type described in “[Expressions](#)” on page 147. It must not include a column name. Host structures are not supported.

NULL

Specifies that the new value for the variable is the null value.

row-fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding *variable*. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

INTO *variable*,...

Identifies one or more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. In the operational form of INTO, a reference to a host structure is replaced by a reference to each of its variables. The first value specified is assigned to the first variable, the second value to the second variable, and so on.

Notes

Variable assignment: Each assignment to a variable is performed according to the retrieval assignment rules described in “Assignments and comparisons” on page 83.¹³² If the number of variables is less than the number of values in the row, an SQL warning (SQLSTATE 01503) is returned (and the SQLWARN3 field of the SQLCA is set to ‘W’). Note that there is no warning if there are more variables than the number of result columns. If a value is null, an indicator variable must be provided for that value.

If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and ‘W’ is assigned to SQLWARN1 in the SQLCA). The actual length of the result may be returned in the indicator variable associated with the variable, if an indicator variable is provided. For further information, see “Variables” on page 128.

If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

If the specified variable is a C NUL-terminated host variable and is not large enough to contain the result and the NUL-terminator:

- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
 - The result is truncated.
 - The last character is the NUL-terminator.
 - The value ‘W’ is assigned to SQLWARN1 in the SQLCA.
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
 - The NUL-terminator is not returned.
 - The value ‘N’ is assigned to SQLWARN1 in the SQLCA.

Result column evaluation considerations: If an error occurs while evaluating a result column in the expression list of a VALUES INTO statement as the result of an arithmetic expression (such as division by zero, or overflow) or a numeric or character conversion error, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to the value of -2. Processing of the statement continues and a warning is returned. If an indicator variable is not provided, an error is returned and no more values are assigned to variables. It is possible that some values have already been assigned to variables and will remain assigned when the error is returned.

When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, depending on how much of the value would have to be truncated, a warning or error is returned. See “Datetime assignments” on page 90 for details.

Multiple assignments: If more than one variable is specified in the INTO clause, all *expressions* are evaluated before the assignments are performed. Thus, references to a *variable* in an *expression* are always the value of the *variable* prior to any assignment in the VALUES INTO statement.

Examples

Example 1: Assign the value of the CURRENT PATH special register to host variable HV1.

```
EXEC SQL VALUES CURRENT PATH  
    INTO :HV1;
```

Example 2: Assume that LOB locator LOB1 is associated with a CLOB value. Assign a portion of the CLOB value to host variable DETAILS using the LOB locator, and assign CURRENT TIMESTAMP to the host variable TIMETRACK.

¹³² If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see “Standards compliance” on page xix.

```
EXEC SQL VALUES (:LOB1,1,35), CURRENT TIMESTAMP
    INTO :DETAILS, :TIMETRACK;
```

WHENEVER

The WHENEVER statement specifies the action to be taken when a specified exception condition occurs.

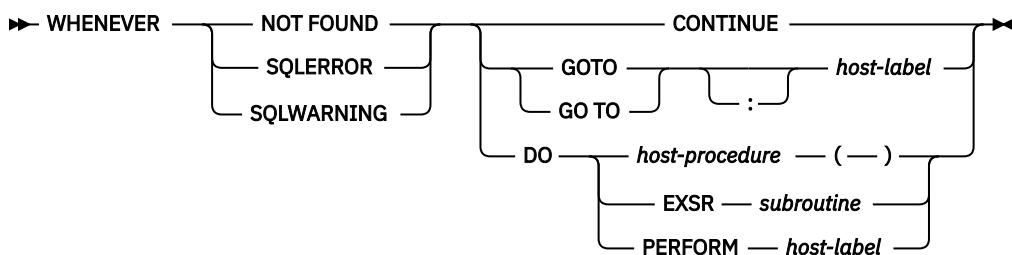

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX. See the [Embedded SQL Programming](#) topic collection for information about handling errors in REXX.

Authorization

None required.

Syntax

Description

The NOT FOUND, SQLERROR, or SQLWARNING clause is used to identify the type of exception condition.

NOT FOUND

Identifies any condition that results in an SQLSTATE of '02000' or an SQLCODE of +100.

SQLERROR

Identifies any condition that results in a negative SQLCODE.

SQLWARNING

Identifies any condition that results in an SQLSTATE value where the first two characters are '01' or a warning condition (SQLWARN0 is 'W'), or that results in a positive SQLCODE other than +100.

The CONTINUE, GO TO, or DO clauses are used to specify the next statement to be executed when the identified type of exception condition exists.

CONTINUE

Specifies the next sequential instruction of the source program.

GOTO or GO TO host-label

Specifies the statement identified by *host-label*. For *host-label*, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language. In a COBOL program, for example, it can be a *section-name* or an unqualified *paragraph-name*.

DO host-procedure

Indicates that a call should be made to a host language procedure. After the procedure has completed, execution will continue with the next sequential instruction of the program. This clause can only be used in C, C++, ILE COBOL, and ILE RPG. The rules for the target of the call depend upon the host language. No parameters may be passed on the call nor can any results be obtained from the call.

DO EXSR subroutine

Indicates that an RPG subroutine should be called with the RPG Invoke Subroutine (EXSR) operation. After the subroutine has completed, execution will continue with the next sequential instruction of the program. This clause can only be used in ILE RPG.

DO PERFORM host-label

Indicates that a COBOL procedure should be called with the COBOL PERFORM statement. After the procedure has completed, execution will continue with the next sequential instruction of the program. This clause can only be used in ILE COBOL. The *host-label* can be a section-name or an unqualified paragraph-name.

Notes

WHENEVER statement scope: Every executable SQL statement in a program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the program, not their execution sequence.

An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which CONTINUE is specified.

SQL does support nested programs in COBOL, C, and RPG. However, SQL does not honor normal COBOL, C, and RPG scoping rules. That is, the last WHENEVER statement specified in the program source prior to the nested procedure is still in effect for that nested program. The label referenced in the WHENEVER statement must be duplicated within that inner program. Alternatively, the inner program could specify a new WHENEVER statement.

For ILE RPG, the SQL TAG statement can be used to generate the *host-label* branch location for the GOTO. See “[TAG](#)” on page 1338.

Examples

The following statements can be embedded in a COBOL program.

- *Example 1:* Go to the label HANDLER for any statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR GOTO HANDLER END-EXEC.
```

- *Example 2:* Continue processing for any statement that produces a warning.

```
EXEC SQL WHENEVER SQLWARNING CONTINUE END-EXEC.
```

- *Example 3:* Go to the label ENDDATA for any statement that does not return data when expected to do so.

```
EXEC SQL WHENEVER NOT FOUND GOTO ENDDATA END-EXEC.
```

- *Example 4:* Call the program or procedure specified by the RPG prototype ERRORPROC for any statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR DO ERRORPROC();
```

- *Example 5:* Call the program or procedure specified by the C prototype errorproc for any statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR DO errorproc();
```

Chapter 8. SQL procedural language (SQL PL)

SQL can be used as a structured programming language to write the routine body for SQL functions, SQL procedures, SQL triggers, and compound (dynamic) statements. This is known as the SQL procedural language, also referred to as SQL PL.

SQL procedures and SQL functions are collectively referred to as SQL routines. SQL procedures are created by specifying an SQL routine body on the CREATE PROCEDURE statement. SQL functions are created by specifying an SQL routine body on the CREATE FUNCTION statement. SQL triggers are created by specifying an SQL routine body on the CREATE TRIGGER statement. A compound (dynamic) statement is defined by specifying an SQL routine body on the compound (dynamic) statement.

An SQL procedure can also be altered. The OR REPLACE option on the CREATE PROCEDURE or CREATE FUNCTION statement can be used to replace an SQL routine with a new version. You can also specify a new SQL routine body on the ALTER PROCEDURE statement or the ALTER FUNCTION statement.

An SQL routine body must be a single SQL statement which may be an SQL control statement.

The SQL routine body is the executable part of the procedure, function, or trigger that is transformed by the database manager into a program or service program. When an SQL routine, trigger, or global variable is created, SQL creates temporary source files (QTEMP/QSQLSRC and QTEMP/QSQLT00000) that will contain C source code with embedded SQL statements. When SQL creates these temporary source files, a record length of 160 is used and the CCSID value of the source statement is set as the CCSID value for the new file. If either of these source files exist, they will be modified if needed to have the same CCSID as the source. The record length of these source files should be 160 or unexpected results may occur. The name of the source file member is the same as the system name of the routine, trigger, or global variable. If DBGVIEW(*SOURCE) is specified, SQL creates the root source for the routine or trigger in source file QSQDSRC in the same library as the procedure, function, or trigger.

An SQL procedure is created as a program (*PGM) or service program (*SRVPGM) object using the CRTPGM or CRTSRVPGM command. An SQL function is created as a service program object. An SQL trigger is created as a program object. The program or service program is created in the library that is the implicit or explicit qualifier of the procedure, function, or trigger name.

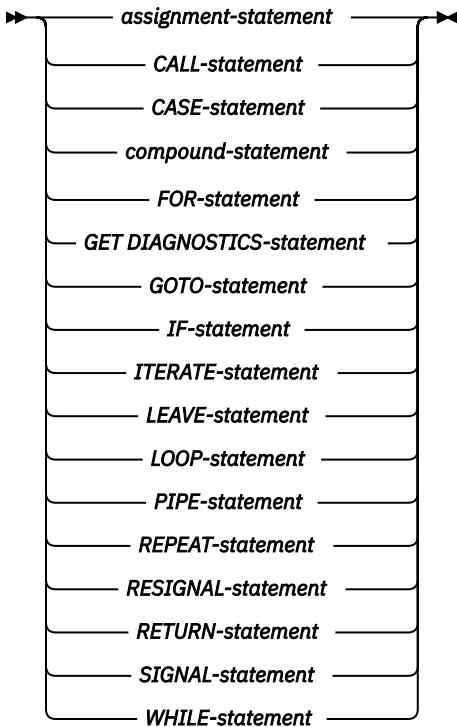

When the program or service program is created, the SQL statements, including most control statements, become embedded SQL statements in the program or service program. The CALL, SIGNAL, RESIGNAL, and GET DIAGNOSTIC control statements also become embedded SQL statements in the program or service program.

The specified procedure or function is registered in the SYSROUTINES and SYSPARMS catalog tables, and an internal link is created from SYSROUTINES to the program. When the procedure is called using the SQL CALL statement or when the function is invoked in an SQL statement, the program associated with the routine is called. The specified SQL trigger is registered in the SYSTRIGGERS catalog table.

SQL control statements

Control statements are SQL statements that allow SQL to be used as a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL-control-statement

Control statements are supported in SQL procedures, SQL functions, SQL triggers, and compound (dynamic) statements.

References to SQL parameters and SQL variables

SQL parameters and SQL variables can be referenced anywhere in an SQL procedure statement where an expression or variable can be specified.

Host variables cannot be specified in SQL functions, SQL procedures, SQL triggers, or compound (dynamic) statements. SQL parameters can be referenced anywhere in the routine and can be qualified with the routine name. SQL variables can be referenced anywhere in the compound statement in which they are declared, including any statement that is directly or indirectly nested within that compound statement. If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label.

All SQL parameters and SQL variables are considered nullable except SQL variables that are explicitly declared as NOT NULL. The name of an SQL parameter or SQL variable in an SQL routine can be the same as the name of a column in a table or view referenced in the routine. The name of an SQL variable can also be the same as the name of another SQL variable declared in the same routine. This can occur when the two SQL variables are declared in different *compound-statements*. The *compound-statement* that contains the declaration of an SQL variable determines the scope of that variable. See “[compound-statement](#)” on page 1374, for more information.

Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, global variable, SQL variable, or SQL parameter. If the name is not qualified, or qualified but still ambiguous, the following rules describe how the name is resolved. The name is resolved by checking for a match in the following order:

- If the tables and views specified in an SQL routine body exist at the time the routine is created, the name will first be checked as a column name.
- If not found as a column, it will then be checked as an SQL variable name. The SQL variable can be declared within the *compound-statement* that contains the reference, or within a compound statement in which that compound statement is nested. If two SQL variables are within the same scope and have the same name,¹³³ the SQL variable that is declared in the innermost compound statement is used.

- If not found as an SQL variable name, the name will be checked as an SQL parameter name.

If the name is still not resolved as a column, SQL variable, or SQL parameter and the scope of the name included a table or view that does not exist at the current server, it will be assumed to be a column or global variable. If all the tables and views exist at the current server, it will be assumed to be a global variable. If the SQL_GVAR_BUILD_RULE QAQQINI option is *EXIST and the global variable does not exist, an error will be issued.

The name of an SQL variable or SQL parameter in an SQL routine can be the same as the name of an identifier used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier or to the SQL parameter or SQL variable. Qualified SQL parameters and SQL variables are not supported for these names.

- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL parameter name or SQL variable name. If not found as an SQL variable or SQL parameter name, it will then be used as an identifier.
- In the CONNECT, DISCONNECT, RELEASE, and SET CONNECTION statements, the name is used as an identifier.
- In the CALL statement, the name is used as an identifier.
- In the ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements when used in a CREATE TRIGGER statement, the name is used as an identifier.

References to SQL condition names

The name of an SQL condition can be the same as the name of another SQL condition declared in the same routine. This can occur when the two SQL conditions are declared in different *compound-statements*.

The *compound-statement* that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. See “[compound-statement](#)” on page 1374, for more information.

References to SQL cursor names

The name of an SQL cursor can be the same as the name of another SQL cursor declared in the same routine. This can occur when the two SQL cursors are declared in different *compound-statements*. The cursor name specified in a FOR statement can be the same as the name of another SQL cursor declared in the same *compound-statement*.

The *compound-statement* that contains the declaration of an SQL cursor determines the scope of that cursor name. A cursor name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a cursor name, the cursor that is declared in the innermost compound statement is the cursor that is used. See “[compound-statement](#)” on page 1374, for more information.

References to SQL labels

Labels can be specified at the beginning of most SQL procedure statements. If a label is specified on an SQL procedure statement, it must be unique from other labels within the same scope. A label must not be the same as any other label within the same compound statement, must not be the same as a label specified on the compound statement itself, and if the compound statement is nested within another

¹³³ Which can happen if they are declared in different compound statements.

compound statement, the label must not be the same as the label specified on any higher level compound statement. The label must not be the same as the name of the SQL function, SQL procedure, or SQL trigger that contains the SQL procedure statement.

Specifying a label for an SQL procedure statement defines that label and determines the scope of that label. A label name can only be referenced within the compound statement in which it is defined, including any statement that is directly or indirectly nested within that compound statement. A label can be specified as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for the statement that references the label as a target.

Summary of 'name' scoping in nested compound statements

Nested compound statements can be used within an SQL routine to define the scope of SQL variable declarations, cursors, condition names, and condition handlers.

Additionally, labels have a defined scope in the context of nested compound statements. However the rules for name space, and how non-unique names can be referenced, differs depending on the type of name. The following table summarizes these differences.

Table 130. Summary of 'Name' Scoping in Nested Compound Statements

Type of name	Must be unique within...	Qualification allowed?	Can be referenced within...
SQL variable	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.	Yes, can be qualified with the label of the compound statement in which the variable was declared.	the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When multiple SQL variables are defined with the same name you can use a label to explicitly refer to a specific variable that is not the most local in scope.
condition	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.	No	the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Can be used in the declaration of a condition handler, or in a SIGNAL or RESIGNAL statement. Note: When multiple conditions are defined with the same name there is no way to explicitly refer to the condition that is not the most local in scope.
cursor	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.	No	the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Note: When multiple cursors are defined with the same name there is no way to explicitly refer to the cursor that is not the most local in scope. However, if the cursor is defined as a result set cursor (for example, the WITH RETURN clause was specified as part of the cursor declaration), the invoking application can access the result set.

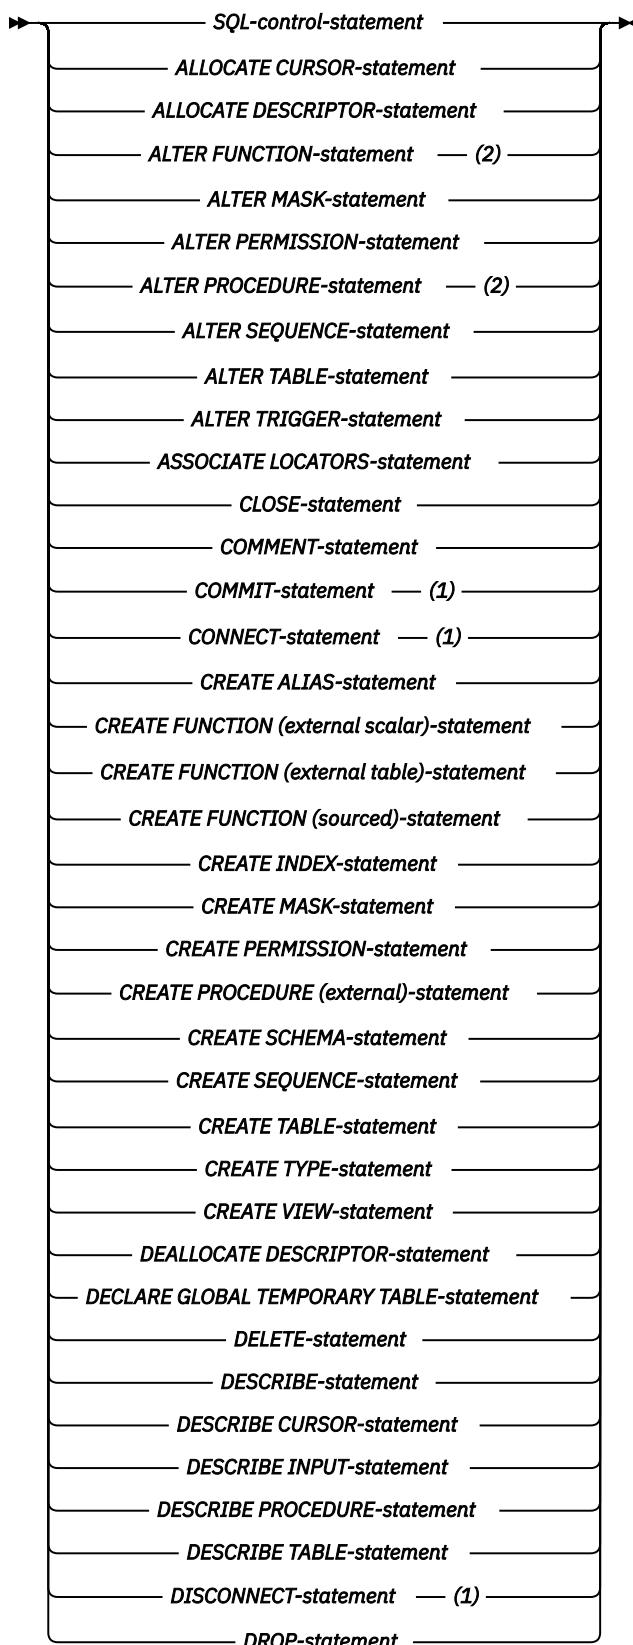

Table 130. Summary of 'Name' Scoping in Nested Compound Statements (continued)

Type of name	Must be unique within...	Qualification allowed?	Can be referenced within...
label	the compound statement that declared the variable, including any declarations in compound statements that are nested within that compound statement.	No	the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Use a label to qualify the name of an SQL variable or as the target of a GOTO, LEAVE, or ITERATE statement.

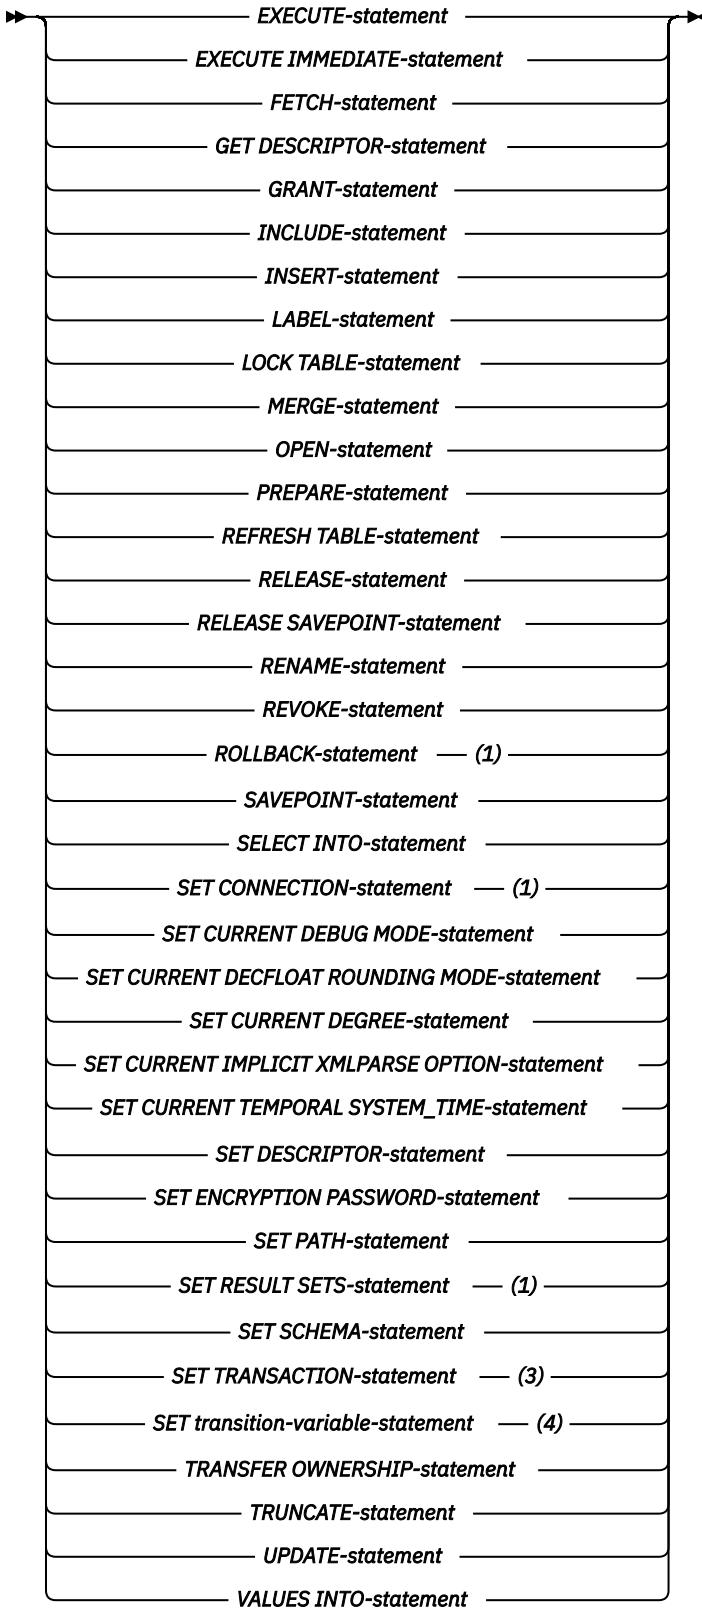

SQL-procedure-statement

An SQL control statement may allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

Syntax

Syntax (continued)

Notes:

1. A COMMIT, ROLLBACK, CONNECT, DISCONNECT, SET CONNECTION, or SET RESULT SETS statement is only allowed in an SQL procedure.
2. An ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), or ALTER FUNCTION (SQL table) statement with a REPLACE keyword is not allowed in an *SQL-routine-body*.

3. A SET TRANSACTION statement is only allowed in an SQL function or trigger.
4. A *SET transition-variable-statement* is only allowed in a trigger. A *fullselect* and *VALUES-statement* can also be specified in a trigger.

Notes

Comments: Comments can be included within the body of an SQL procedure. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of a comment.

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

Detecting and processing error and warning conditions: As an SQL statement is executed, the database manager stores information about the processing of the statement in a diagnostics area (including the SQLSTATE and SQLCODE), unless otherwise noted in the description of the SQL statement. A completion condition indicates the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the SQL statement was not successful.

A condition handler can be defined in a compound statement to execute when an exception condition, a warning condition, or a not found condition occurs. The declaration of a condition handler includes the code that is to be executed when the condition handler is activated. When a condition other than a successful completion occurs in the processing of *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition. See “[compound-statement](#)” on page 1374 for information about defining condition handlers. The code in the condition handler can check for a warning condition, not found condition, or exception condition and take the appropriate action. Use one of the following methods at the beginning of the body of a condition handler to check the condition in the diagnostics area that caused the handler to be activated:

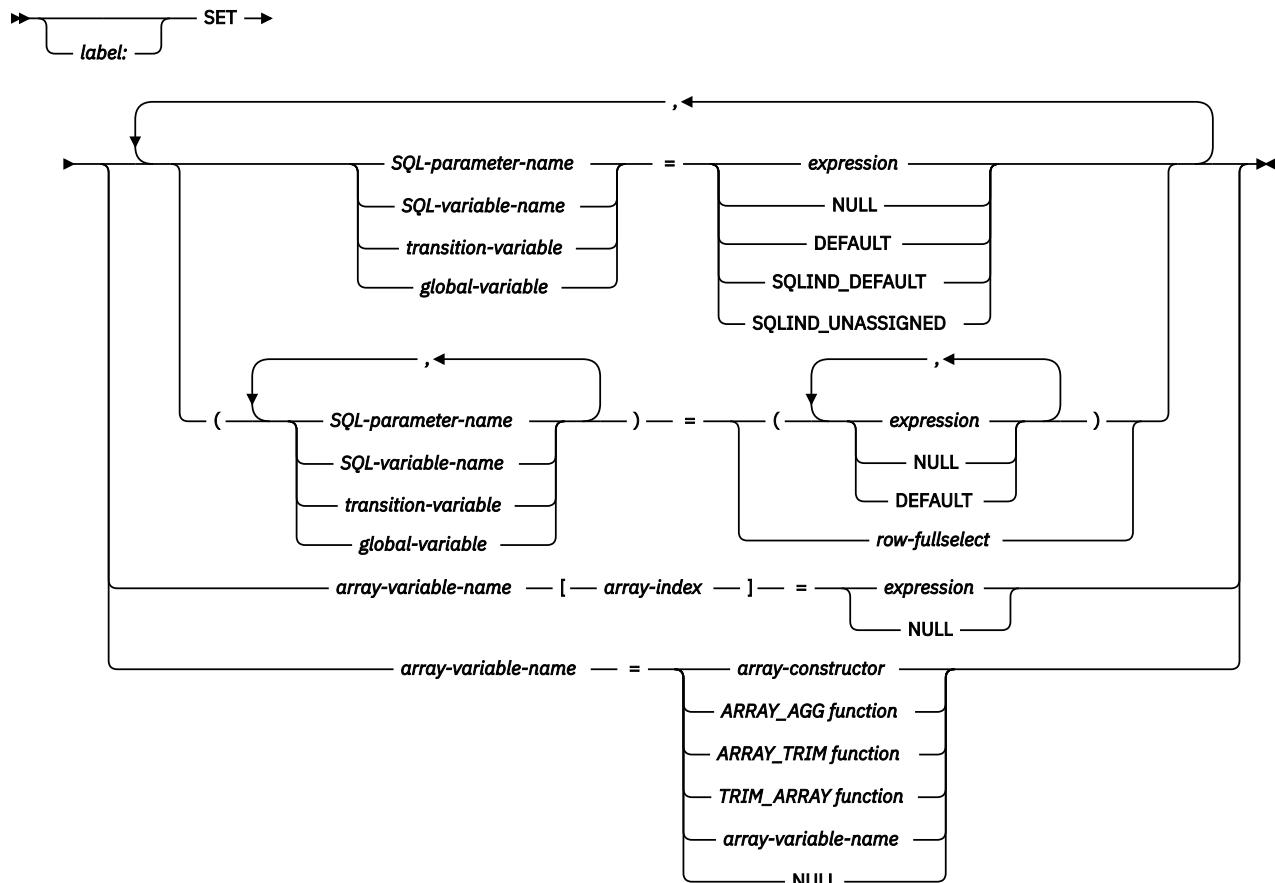

- Issue a GET DIAGNOSTICS statement to request the condition information. See “[GET DIAGNOSTICS statement](#)” on page 1383.
- Test the SQL variables SQLSTATE and SQLCODE.

If the condition is a warning and there is not a handler for the condition, the above two methods can also be used outside of the body of a condition handler immediately following the statement for which the condition is wanted. If the condition is an error and there is not a handler for the condition, the routine or trigger terminates with the error condition.

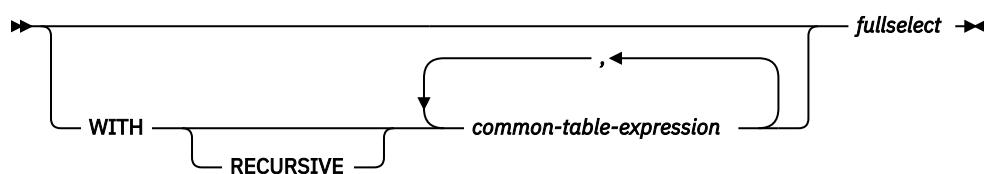

assignment-statement

The *assignment-statement* assigns a value to an SQL parameter, an SQL variable, or a *transition-variable*.

Syntax

row-fullselect

Description

label

Specifies the label for the *assignment-statement* statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

SQL-parameter-name

Identifies the SQL parameter that is the assignment target. The SQL parameter must be specified in *parameter-declaration* in the CREATE PROCEDURE or CREATE FUNCTION statement.

SQL-variable-name

Identifies the SQL variable that is the assignment target. SQL variables can only be declared in a *compound-statement* and must be declared before they are used.

transition-variable

Identifies the column to be updated in the new row. A *transition-variable* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value. An OLD *transition-variable* must not be identified. A *transition-variable* can only be modified in a BEFORE trigger.

A *transition-variable* must not be identified more than once in the same *assignment-statement*.

Values are assigned to *transition-variables* according to the storage assignment rules. For more information see “[Assignments and comparisons](#)” on page 83.

global-variable

Identifies the global variable that is the assignment target.

expression

Specifies the expression or value that is the source for the assignment.

An *expression* may contain references to OLD and NEW *transition-variables*. If the CREATE TRIGGER statement contains both OLD and NEW clauses, references to *transition-variables* must be qualified by the *correlation-name*.

NULL

Specifies the null value. For *transition-variables*, NULL can only be specified for nullable columns.

DEFAULT

Specifies that the default value will be used. DEFAULT can only be specified for a global variable and in SQL triggers for transition variables. DEFAULT is not allowed for a *transition-variable* associated with a GENERATED column. Only one global variable can be assigned in the SET statement when DEFAULT is used.

SQLIND_DEFAULT

Specifies that the indicator associated with this variable is assigned the extended indicator value of DEFAULT. The target of the assignment must be an SQL variable or an SQL parameter. An error is returned if the variable does not allow a null value. Only one variable can be assigned in the SET statement when SQLIND_DEFAULT is used.

SQLIND_UNASSIGNED

Specifies that the indicator associated with this variable is assigned the extended indicator value of UNASSIGNED. The target of the assignment must be an SQL variable or an SQL parameter. An error is returned if the variable does not allow a null value. Only one variable can be assigned in the SET statement when SQLIND_UNASSIGNED is used.

row-fullselect

A fullselect that returns a single result row. The result column values are assigned to the corresponding variable or parameter. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

WITH common-table-expression

Specifies a common table expression. For an explanation of common table expression, see “[common-table-expression](#)” on page 643.

fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

array-variable-name

Identifies an SQL variable or parameter. The variable or parameter must be of an array type.

[array-index]

Numeric expression that specifies which element in the array will be the target of the assignment. The array index must be of an exact numeric type with zero scale; it cannot be null. Its value must be between 1 and the maximum cardinality defined for the array.

array-constructor

Specifies the value of an array constructor. See “[ARRAY constructor](#)” on page 161.

TRIM_ARRAY function

Specifies the TRIM_ARRAY scalar function. See “[TRIM_ARRAY](#)” on page 500.

Notes

Assignment rules: Assignments in the assignment statement must conform to the SQL retrieval assignment rules as described in “[Assignments and comparisons](#)” on page 83.¹³⁴

If the assignment is of the form SET $A[\text{idx}] = \text{rhs}$, where A is an array variable name, idx is an expression used as the array index, and rhs is an expression of a compatible type as the array element, then:

1. If array A is the null value, set A to the empty array.
2. Let C be the cardinality of array A .
3. If idx is less than or equal to C , the value in the position identified by idx is replaced by the value of rhs .
4. If idx is greater than C , then:
 - a. The value in position i , for i greater than C and less than idx , is set to the null value.
 - b. The value in position idx is set to the value of rhs .
 - c. The cardinality of A is set to idx .

Assignments involving SQL parameters: An IN parameter can appear on the left or right side of an *assignment-statement*. When control returns to the caller, the original value of the IN parameter is retained. An OUT parameter can also appear on the left or right side of an *assignment-statement*. If used without first being assigned a value, the value is null. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller. For an INOUT parameter, the first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

Multiple SQL parameter or SQL variable assignments: If more than one variable is specified as the target of the *assignment-statement*, the targets of the *assignment-statement* are completely evaluated before the assignments are performed. Thus, a reference to a variable in a target expression is always the value of the variable prior to any assignment.

Extended indicator values: For the extended indicator values of SQLIND_DEFAULT and SQLIND_UNASSIGNED to be recognized, the SQL routine or SQL trigger must be created with the SET OPTION EXTIND = *YES. For more information about extended indicator values, see “[References to host variables](#)” on page 130.

Arrays: If an assignment is to an array or array element, only one assignment is allowed in the statement.

Special Registers: If a variable has been declared with an identifier that matches the name of a special register (such as PATH), then the variable must be delimited to distinguish it from assignment to the special register (for example, SET "PATH" = 1; for a variable called PATH declared as an integer).

Considerations for SQLSTATE and SQLCODE variables: Assignment to these variables is not prohibited; however, it is not recommended as assignment does not affect the diagnostics area or result in the activation of condition handlers. The SQLCODE and SQLSTATE will be reset and the diagnostics area or SQLCA initialized for each *assignment-statement* other than *assignment-statements* that:

- assign the SQLSTATE or SQLCODE variable to another variable or
- set a constant value into the SQLSTATE or SQLCODE variable.

Examples

Example 1: Increase the SQL variable p_salary by 10 percent.

¹³⁴ If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see “[Standards compliance](#)” on page xix.

```
SET p_salary = p_salary + (p_salary * .10)
```

Example 2: Set SQL variable p_salary to the null value

```
SET p_salary = NULL
```

Example 3: Set the SQL array variable p_phonenumbers to an array of fixed numbers.

```
SET p_phonenumbers = ARRAY[9055553907, 4165554213, 4085553678]
```

Example 4: Set the SQL array variable p_phonenumbers to an array of numbers retrieved from the PHONENUMBER table.

```
SET p_phonenumbers = ARRAY  
[SELECT NUMBER FROM PHONENUMBERS  
WHERE EMPID = 624]
```

Example 5: Assign p_mynumber to the first and tenth elements of the SQL array variable p_phonenumbers. After the first assignment, the cardinality of p_phonenumbers is 1. After the second assignment, the cardinality is 10, and elements 2 to 9 have been implicitly assigned the null value.

```
SET p_phonenumbers[1] = p_mynumber  
SET p_phonenumbers[10] = p_mynumber
```

Example 6: Ensure that the salary column is never greater than 50000. If the new value is greater than 50000, set it to 50000.

```
CREATE TRIGGER LIMIT_SALARY  
BEFORE INSERT ON EMPLOYEE  
REFERENCING NEW AS NEW_VAR  
FOR EACH ROW MODE DB2SQL  
WHEN (NEW_VAR.SALARY > 50000)  
BEGIN ATOMIC  
SET NEW_VAR.SALARY = 50000;  
END
```

Example 7: When the job title is updated, increase the salary based on the new job title. Assign the years in the position to 0.

```
CREATE TRIGGER SET_SALARY  
BEFORE UPDATE OF JOB ON STAFF  
REFERENCING OLD AS OLD_VAR  
        NEW AS NEW_VAR  
FOR EACH ROW MODE DB2SQL  
BEGIN ATOMIC  
SET (NEW_VAR.SALARY, NEW_VAR.YEARS) =  
(OLD_VAR.SALARY * CASE NEW_VAR.JOB  
    WHEN 'Sales' THEN 1.1  
    WHEN 'Mgr' THEN 1.05  
    ELSE 1 END ,0);  
END
```

CALL statement

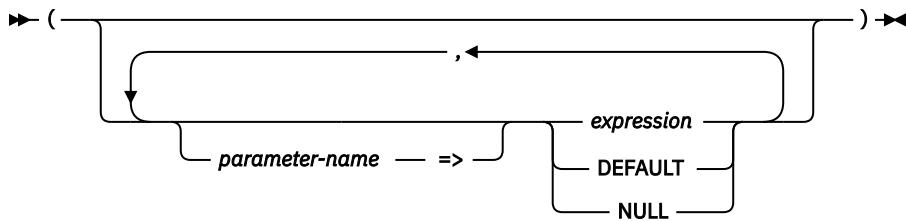

The CALL statement invokes a procedure. The syntax of CALL in an SQL function, SQL procedure, or SQL trigger is a subset of what is supported as a CALL statement in other contexts.

See “[CALL](#)” on page 772 for details.

Syntax

►  CALL — *procedure-name* — *argument-list* ►
label:

argument-list

Description

label

Specifies the label for the CALL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see [“References to SQL labels” on page 1361](#).

procedure-name

Identifies the procedure to call. The *procedure-name* must identify a procedure that exists at the current server.

argument-list

Identifies a list of values to be passed as parameters to the procedure. The *n*th unnamed argument corresponds to the *n*th parameter in the procedure.

Each parameter defined (using CREATE PROCEDURE) as OUT must be specified as either a *SQL-variable-name* or a *SQL-parameter-name*. A default cannot be specified for an OUT parameter. If a default is used for an INOUT parameter, then the default expression is used to initialize the parameter for input to the procedure. No value is returned for this parameter when the procedure exits.

When a procedure is called, arguments must be specified for all parameters that are not defined to have a default value. When an argument is assigned to a parameter using the named syntax, then all the arguments that follow it must also be assigned using the named syntax.

Any references to date, time, or timestamp special register values in the argument list will use one clock reading for any default expressions and a separate clock reading for any references in the explicit arguments.

The number of arguments specified must be the same as the number of parameters of a procedure defined at the current server with the specified *procedure-name*.

The application requester assumes all parameters that are variables are INOUT parameters. All parameters that are not variables are assumed to be input parameters. The actual attributes of the parameters are determined by the current server.

parameter-name

Name of the parameter to which the argument value is assigned. The name must match a parameter name defined for the procedure. Named arguments correspond to the same named parameter regardless of the order in which they are specified in the argument list. When an argument is assigned to a parameter by name, all the arguments that follow it must also be assigned by name.

A named argument must be specified only one time (implicitly or explicitly).

Named arguments are not allowed on a call to a procedure that was not defined using a CREATE PROCEDURE statement.

expression

An *expression* of the type described in [“Expressions” on page 147](#), that does not include an aggregate function or column name.

DEFAULT

Specifies the default as defined in the CREATE PROCEDURE statement is used as an argument to the procedure; otherwise the NULL value is used.

NULL

Specifies a null value as an argument to the procedure.

Notes

Rules for arguments to OUT and INOUT parameters: Each OUT or INOUT parameter must be specified as an SQL parameter or SQL variable.

Special registers: The initial value of a special register in a procedure is inherited from the caller of the procedure. A value assigned to a special register within the procedure is used for the entire SQL procedure and will be inherited by any procedure subsequently called from that procedure. When a procedure returns to its caller, the special registers are restored to the original values of the caller.

Related information: See “[CALL](#)” on page 772 for more information.

Example

Call procedure *proc1* and pass SQL variables as parameters.

```
CALL proc1(v_empno, v_salary)
```

CASE statement

The CASE statement selects an execution path based on multiple conditions.

Syntax

```
► CASE [label:] simple-when-clause [searched-when-clause] [else-clause] END CASE ►
```

simple-when-clause

```
► expression WHEN expression THEN SQL-procedure-statement ;
```

searched-when-clause

```
► WHEN search-condition THEN SQL-procedure-statement ;
```

else-clause

```
► ELSE SQL-procedure-statement ;
```

Description

label

Specifies the label for the CASE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

simple-when-clause

The value of the *expression* prior to the first WHEN keyword is tested for equality with the value of each *expression* that follows the WHEN keyword. If the comparison is true, the statements in the

associated THEN clause are executed and processing of the CASE statement ends. If the result is unknown or false, processing continues to the next comparison. If the result does not match any of the comparisons, and an ELSE clause is present, the statements in the ELSE clause are executed.

searched-when-clause

The *search-condition* following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If it evaluates to false, or unknown, the next *search-condition* is evaluated. If no *search-condition* evaluates to true and an ELSE clause is present, the statements in the ELSE clause are executed.

else-clause

If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, then the statements in the *else-clause* are executed.

If none of the conditions specified in the WHEN are true, and an ELSE clause is not specified, an error is issued at runtime, and the execution of the CASE statement is terminated (SQLSTATE 20000).

SQL-procedure-statement

Specifies a statement to execute. See “[SQL-procedure-statement](#)” on page 1363.

Notes

Nesting of CASE statements: CASE statements that use a *simple-when-clause* can be nested up to three levels. CASE statements that use a *searched-when-clause* have no limit to the number of nesting levels.

Considerations for SQLSTATE and SQLCODE variables: When the first *SQL-procedure-statement* in the CASE statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the *expressions* or *search-conditions* of that CASE statement. If a CASE statement does not include an ELSE clause and none of the *search-conditions* evaluate to true, then any error returned from the expression is returned.

Examples

Example 1: Depending on the value of SQL variable v_workdept, update column DEPTNAME in table DEPARTMENT with the appropriate name.

The following example shows how to do this using the syntax for a *simple-when-clause*.

```
CASE v_workdept
  WHEN 'A00'
    THEN UPDATE department SET
      deptname = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE department SET
      deptname = 'DATA ACCESS 2';
  ELSE UPDATE department SET
    deptname = 'DATA ACCESS 3';
END CASE
```

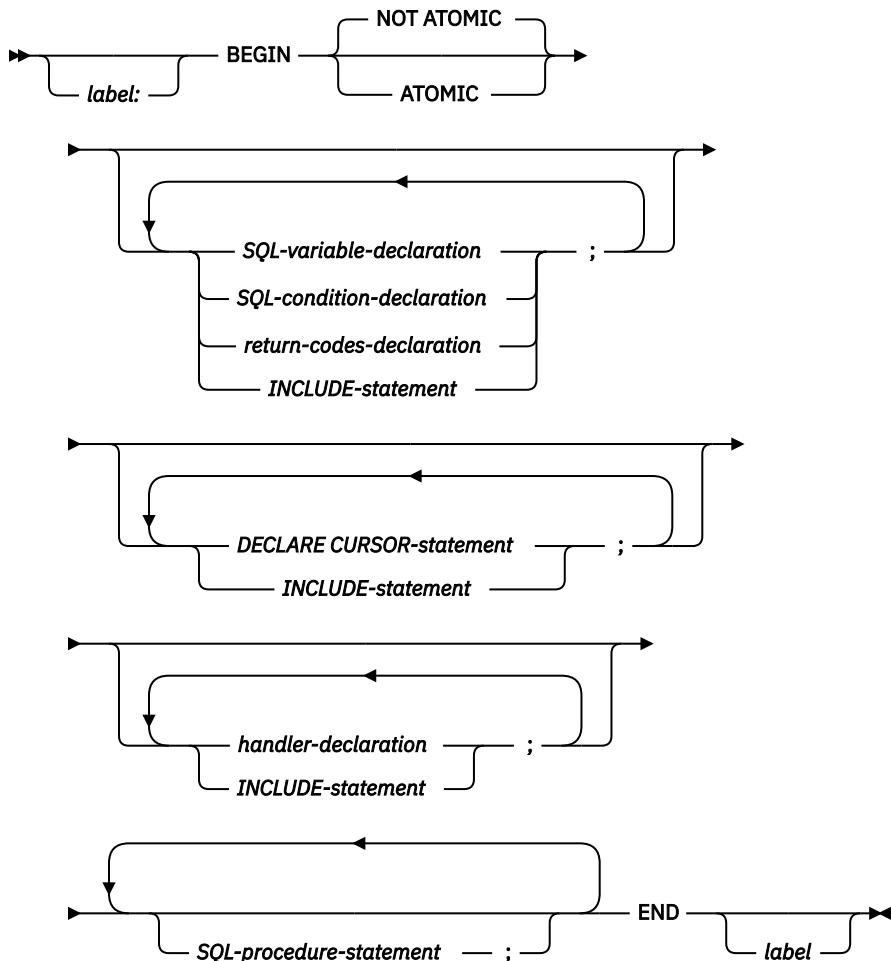

Example 2: The following example shows how to do this using the syntax for a *searched-when-clause*:

```
CASE
  WHEN v_workdept = 'A00'
    THEN UPDATE department SET
      deptname = 'DATA ACCESS 1';
  WHEN v_workdept = 'B01'
    THEN UPDATE department SET
      deptname = 'DATA ACCESS 2';
  ELSE UPDATE department SET
    deptname = 'DATA ACCESS 3';
END CASE
```

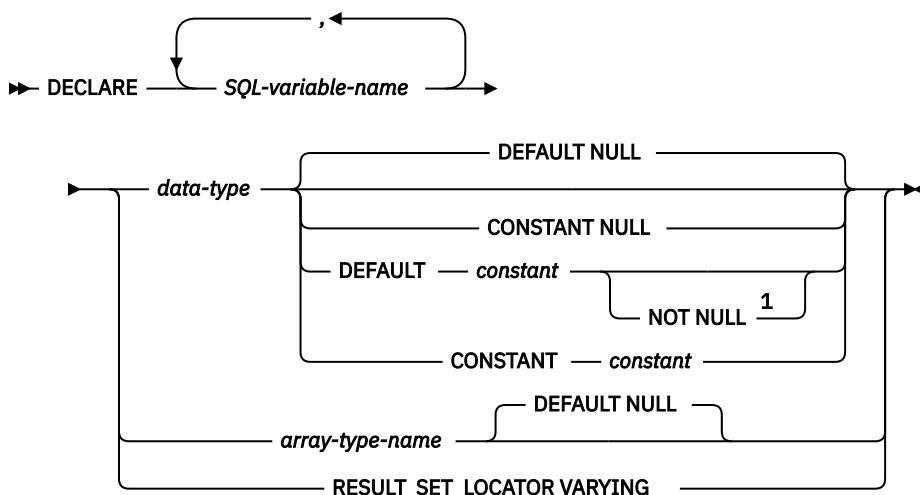

compound-statement

A compound statement groups other statements together in an SQL procedure. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

Syntax

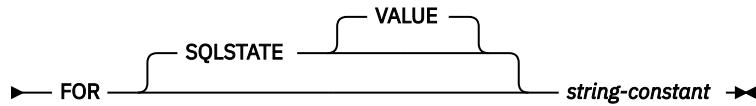

SQL-variable-declaration

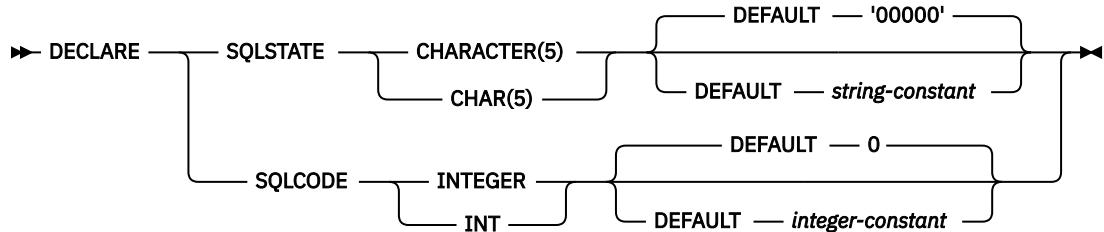

SQL-condition-declaration

►► DECLARE — SQL-condition-name — CONDITION →

return-codes-declaration

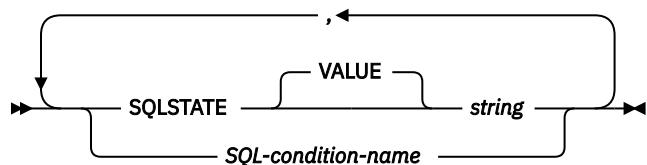

handler-declaration

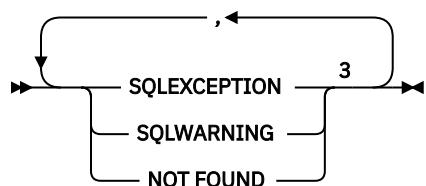

►► SQL-procedure-statement ►►

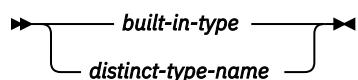

specific-condition-value

general-condition-value

data-type

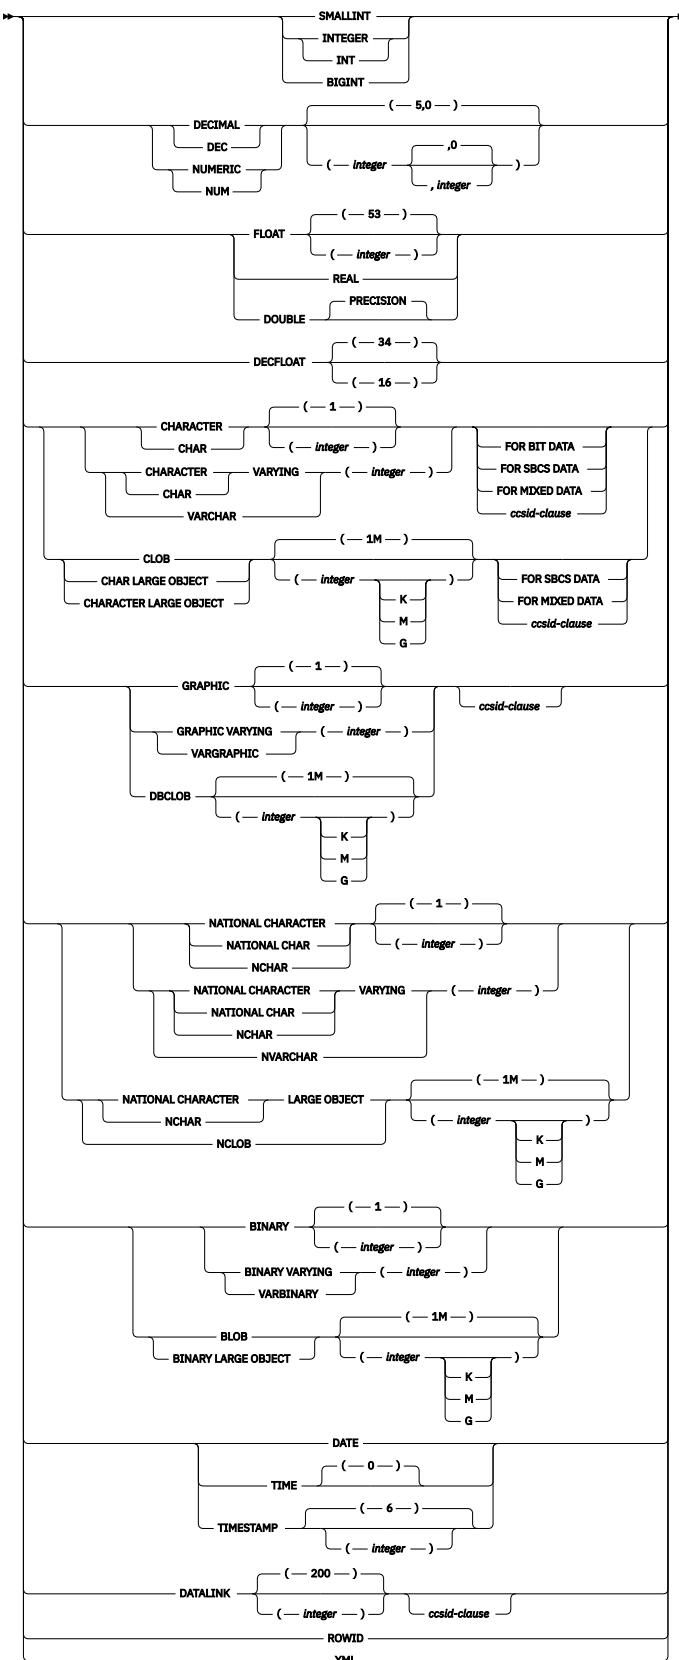

Notes:

¹ The DEFAULT and NOT NULL clauses can be specified in either order.

² specific-condition-value and general-condition-value cannot be specified in the same handler declaration.

³ The same clause must not be specified more than once.

built-in-type

ccsid-clause

►► CCSID — *integer* ►►

Description

label

Specifies the label for the *compound-statement*. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

ATOMIC

ATOMIC indicates that an unhandled exception condition within the *compound-statement* causes the *compound-statement* to be rolled back. If ATOMIC is specified, COMMIT or ROLLBACK statements cannot be specified in the compound statement (ROLLBACK TO SAVEPOINT may be specified).

NOT ATOMIC

NOT ATOMIC indicates that an unhandled exception condition within the *compound-statement* does not cause the *compound-statement* to be rolled back. If NOT ATOMIC is specified in the outermost compound statement of an SQL trigger, it is treated as ATOMIC.

If ATOMIC is specified in an SQL procedure or function, the routine must have a data classification of MODIFIES SQL DATA.

SQL-variable-declaration

Declares a variable that is local to the *compound-statement*.

SQL-variable-name

Defines the name of a local SQL variable. The database manager converts all undelimited SQL variable names to uppercase. The name must not be the same as another SQL variable within the same *compound-statement*, excluding any declarations in *compound-statements* nested within the *compound-statement*. Do not name SQL variables the same as column names or parameter names. See “[References to SQL parameters and SQL variables](#)” on page 1360 for how SQL variable names are resolved when there are columns with the same name involved in a statement. Variable names should not begin with 'SQL'.

data-type

Specifies the data type of the variable. See “[CREATE TABLE](#)” on page 945 for a description of data type.

If the *data-type* is a graphic string data type, consider specifying CCSID 1200 or 13488 to indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the graphic string variable will be the associated DBCS CCSID for the job.

array-type-name

Specifies that the SQL variable is an array as defined with the CREATE TYPE (Array) statement.

DEFAULT constant or NULL

Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in “[Assignments and comparisons](#)” on page 83. The variable is initialized when the *compound-statement* in which it is declared is entered. If a default value is not specified, the SQL variable is initialized to NULL. SQL variables of type XML cannot have a default value specified. SQL variables of *array-type* are always initialized to NULL.

NOT NULL

Prevents the SQL variable from containing the NULL value. Omission of NOT NULL implies that the variable can be null. SQL variables of type XML cannot have NOT NULL specified.

CONSTANT constant or NULL

Specifies that the SQL variable has a fixed value that cannot be changed. An SQL variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in “[Assignments and comparisons](#)” on page 83.

RESULT_SET_LOCATOR VARYING

Specifies the data type for a result set locator variable.

SQL-condition-declaration

Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name

Specifies the name of the condition. The condition name must be unique within the *compound-statement* (excluding any declarations in *compound-statements* nested within the *compound-statement*) in which it is declared.

FOR SQLSTATE string-constant

Specifies the SQLSTATE associated with this condition. The string constant must be specified as 5 characters. The SQLSTATE class (the first 2 characters) must not be '00'.

return-codes-declaration

Declares special SQL variables called SQLSTATE and SQLCODE that are set for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty *compound-statement*. The SQLSTATE and SQLCODE variables can only be declared in the outermost *compound-statement* of an SQL procedure, SQL function, or SQL trigger.

The SQLSTATE and SQLCODE special variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these special variables is ignored by condition handlers. The SQLSTATE and SQLCODE special variables cannot be set to NULL.

DECLARE CURSOR-statement

Declares a cursor in the routine body. The cursor name must be unique within the *compound-statement*, excluding any declarations in *compound-statements* nested within the *compound-statement*.

A *cursor-name* can only be referenced within the *compound-statement* in which it is declared, including any *compound-statements* nested within the *compound-statement*.

Use an OPEN statement to open the cursor, and a FETCH statement to read rows using the cursor. If the cursor in an SQL procedure and is intended for use as a result set:

- specify WITH RETURN when declaring the cursor
- create the procedure using the DYNAMIC RESULT SETS clause with a non-zero value
- do not specify a CLOSE statement in the *compound-statement*.

Any open cursor that does not meet these criteria is closed at the end of the *compound-statement*.

For more information about declaring a cursor, refer to [“DECLARE CURSOR” on page 1037](#).

handler-declaration

Specifies a *handler*, an *SQL-procedure-statement* to execute when an exception or completion condition occurs in the *compound-statement*.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than once, and cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value. For a list of SQLSTATE values as well as more information, see the [SQL messages and codes topic collection](#).

Furthermore, when two or more condition handlers are declared in a compound statement, no two condition handler declarations may specify the same:

- general condition category or
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value.

A condition handler is active for the set of *SQL-procedure-statements* that follow the *handler-declarations* within the *compound-statement* in which it is declared, including any nested compound statements.

A handler for a condition may exist at several levels of nested compound statements. For example, assume that compound statement *n1* contains another compound statement *n2* which contains another compound statement *n3*. When an exception condition occurs within *n3*, any active handlers within *n3* are first allowed to handle the condition. If no appropriate handler exists in *n3*, then the condition is signaled to *n2* and the active handlers within *n2* may handle the condition. If no appropriate handler exists in *n2*, then the condition is signaled to *n1* and the active handlers within *n1* may handle the condition. If no appropriate handler exists in *n1*, the condition is considered unhandled.

There are three types of condition handlers:

CONTINUE

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement following the one that raised the exception. If the error occurs while executing a comparison as in an IF, CASE, FOR, WHILE, or REPEAT, control returns to the statement following the corresponding END IF, END CASE, END FOR, END WHILE, or END REPEAT.

EXIT

Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound statement that declared the condition handler.

UNDO

Specifies that when the condition handler is activated changes made by the *compound-statement* are rolled back. When the handler completes successfully, control is returned to the end of the *compound-statement*. If UNDO is specified, then ATOMIC must be specified.

UNDO cannot be specified in the outermost *compound-statement* of an SQL function or SQL trigger.

The conditions under which the handler is activated are:

SQLSTATE string

Specifies that the handler is invoked when the specific SQLSTATE occurs. The SQLSTATE class (the first 2 characters) must not be '00'.

SQL-condition-name

Specifies that the handler is invoked when the specific SQLSTATE associated with the condition name occurs. The *SQL-condition-name* must be previously defined in a *SQL-condition-declaration*.

SQLEXCEPTION

Specifies that the handler is invoked when an exception condition occurs. An exception condition is represented by an SQLSTATE value where the first two characters are not '00', '01', or '02'.

SQLWARNING

Specifies that the handler is invoked when a warning condition occurs. A warning condition is represented by an SQLSTATE value where the first two characters are '01'.

NOT FOUND

Specifies that the handler is invoked when a NOT FOUND condition occurs. A NOT FOUND condition is represented by an SQLSTATE value where the first two characters are '02'.

Notes

Nesting compound statements: Compound statements can be nested. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in the *compound-statement*. This can simplify the processing done for each SQL procedure statement. Support for nested compound statements enables the use of a compound statement within the declaration of a condition handler.

Condition handlers: Condition handlers in a *compound-statement* are similar to WHENEVER statements used in external SQL application programs. A condition handler can be defined to automatically get

control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as a result of an exception, warning, or not found condition that is returned by the database manager for the processing of an SQL statement, or the activating condition can be the result of a SIGNAL or RESIGNAL statement issued within the procedure body.

A condition handler is declared within a compound statement, and it is active for the set of *SQL-procedure-statements* that follow all of the condition handler declarations within the compound statement in which the condition handler is declared. To be more specific, the scope of a condition handler declaration H is the list of *SQL-procedure-statements* that follows the condition handler declarations contained within the compound statement in which H appears. This means that the scope of H does not include the statements contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 declared in the same compound statement, H1 will not handle conditions arising in the body of H2, and H2 will not handle conditions arising in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of the condition handler (CONTINUE, EXIT, or UNDO), and the handler action. The type of the condition handler determines where control is returned to after successful completion of the handler action.

Condition handler activation: When a condition other than successful completion occurs in the processing of an *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a routine with nested compound statements, condition handlers that could handle a specific condition may exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at that nesting level could handle the condition, the condition handler that is activated is the most appropriate handler declared in that compound statement.

The most appropriate handler is a handler that is defined in the *compound-statement* which most closely matches the SQLSTATE of the exception or completion condition.

For example, if the innermost compound statement declares a specific handler for SQLSTATE 22001 as well as a handler for SQLEXCEPTION, the specific handler for SQLSTATE 22001 is the most appropriate handler when an SQLSTATE 22001 is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (CONTINUE, EXIT, or UNDO handler) determines where control is returned. Additionally, the SQLSTATE and SQLCODE SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully, and an appropriate handler exists for the condition encountered in the handler action, that condition handler is activated. Otherwise, the condition encountered within the condition handler is unhandled.

Unhandled conditions: If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the SQL procedure, SQL function, or SQL trigger containing the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

Considerations for using SIGNAL or RESIGNAL statements with nested compound statements: If an *SQL-procedure-statement* specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound statement terminates with the specified exception. This happens even if this condition handler or another condition handler in the same compound statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If the compound statement is nested in another compound statement, condition handlers in the higher level

compound statement may handle the exception because those condition handlers are within the scope of the exception.

Null values in SQL parameters and SQL variables: If the value of an SQL parameter or SQL variable is null and it is used in an SQL statement (such as CONNECT or DESCRIBE) that does not allow an indicator variable, an error is returned.

Effect on open cursors: Upon exit from the *compound-statement* for any reason, all open cursors that are declared in that compound statement are closed, unless they are declared to return result sets or unless *ENDACTGRP is specified.

Considerations for SQLSTATE and SQLCODE SQL variables: The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within that compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

Examples

Create a procedure body with a compound statement that performs the following actions.

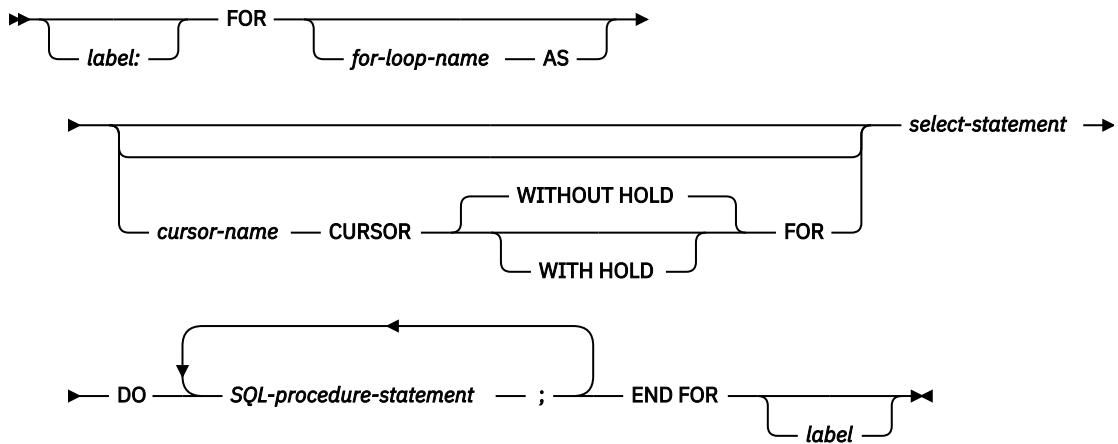

1. Declares SQL variables.
2. Declares a cursor to return the salary of employees in a department determined by an IN parameter.
3. Declares an EXIT handler for the condition NOT FOUND (end of file) which assigns the value 6666 to the OUT parameter medianSalary.
4. Select the number of employees in the given department into the SQL variable v_numRecords .
5. Fetch rows from the cursor in a WHILE loop until 50% + 1 of the employees have been retrieved.
6. Return the median salary.

```
CREATE PROCEDURE DEPT_MEDIAN
(IN deptNumber SMALLINT,
OUT medianSalary DOUBLE)
LANGUAGE SQL
BEGIN
DECLARE v_numRecords INTEGER DEFAULT 1;
DECLARE v_counter INTEGER DEFAULT 0;
DECLARE c1 CURSOR FOR
    SELECT salary FROM staff
    WHERE DEPT = deptNumber
    ORDER BY salary;
DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;
    /* initialize OUT parameter */
    SET medianSalary = 0;
    SELECT COUNT(*) INTO v_numRecords FROM staff
    WHERE DEPT = deptNumber;
OPEN c1;
WHILE v_counter < (v_numRecords / 2 + 1) DO
    FETCH c1 INTO medianSalary;
    SET v_counter = v_counter + 1;
END WHILE;
CLOSE c1;
END
```

FOR statement

The FOR statement executes a statement or group of statements for each row of a table.

Syntax

Description

label

Specifies the label for the FOR statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see [“References to SQL labels” on page 1361](#).

for-loop-name

Specifies the label for the implicit *compound-statement* that is generated to implement the FOR statement. It follows the rules for the label of a *compound-statement* except that it cannot be used with an ITERATE, GOTO, or LEAVE statement within the FOR statement. The *for-loop-name* is used to qualify the column names returned by the specified *select-statement*. It must not be the same as any label within the same scope. For more information, see [“References to SQL labels” on page 1361](#).

Either the *for-loop-name* or *label* can be used to qualify other SQL variable names in the statement.

If *for-loop-name* is specified, then it should be used to qualify any other SQL variable names in the statement when debugging the SQL function, SQL procedure, or SQL trigger.

cursor-name

Names a cursor.

WITH HOLD

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared using the WITH HOLD clause is implicitly closed at commit time only if the connection associated with the cursor is ended during the commit operation. For more information, see [“DECLARE CURSOR” on page 1037](#).

select-statement

Specifies the select statement of the cursor.

Each expression in the select list must have a name. If an expression is not a simple column name, the AS clause must be used to name the expression. If the AS clause is specified, that name is used for the variable and must be unique.

SQL-procedure-statement

Specifies the SQL statements to be executed for each row of the result table of the cursor. The SQL statements should not include an OPEN, FETCH, or CLOSE specifying the cursor name of the FOR statement.

Notes

FOR statement rules: The FOR statement executes one or multiple statements for each row in a result table of the cursor. The cursor is defined by specifying a select list that describes the columns and rows selected. The statements within the FOR statement are executed for each row selected.

The select list must consist of unique column names and the objects referenced in the *select-statement* must exist when the function, procedure, or trigger is created.

The cursor specified in a FOR statement cannot be referenced outside the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

Handler warning: Handlers may be used to handle errors that might occur on the open of the cursor or fetch of a row using the cursor in the FOR statement. Handlers defined to handle these open or fetch conditions should not be CONTINUE handlers as they may cause the FOR statement to loop indefinitely.

Example

In this example, the FOR statement is used to specify a cursor that selects 3 columns from the employee table. For every row selected, SQL variable *fullname* is set to the last name followed by a comma, the first name, a blank, and the middle initial. Each value for *fullname* is inserted into table TNAMES.

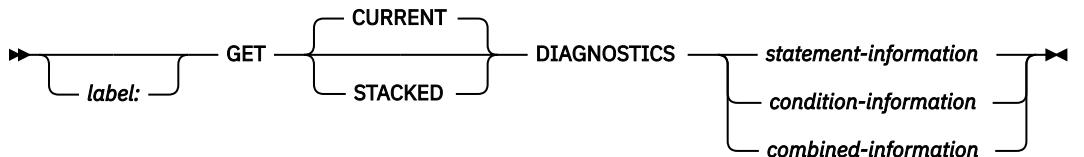

```
BEGIN
  DECLARE fullname CHAR(40);
  FOR v1 AS
    c1 CURSOR FOR
      SELECT firstname, midinit, lastname FROM employee
    DO
      SET fullname =
        lastname || ', ' || firstname || ' ' || midinit;
      INSERT INTO TNAMES VALUES ( fullname );
    END FOR;
END;
```

GET DIAGNOSTICS statement

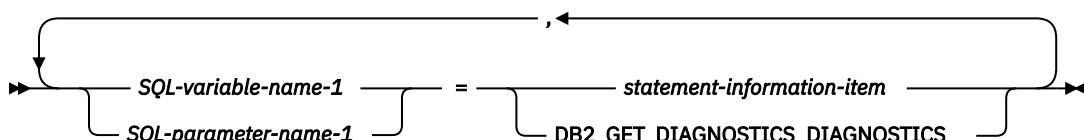

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed. The syntax of GET DIAGNOSTICS in an SQL function, SQL procedure, or SQL trigger is a subset of what is supported as a GET DIAGNOSTICS statement in other contexts.

See [“GET DIAGNOSTICS” on page 1144](#) for details.

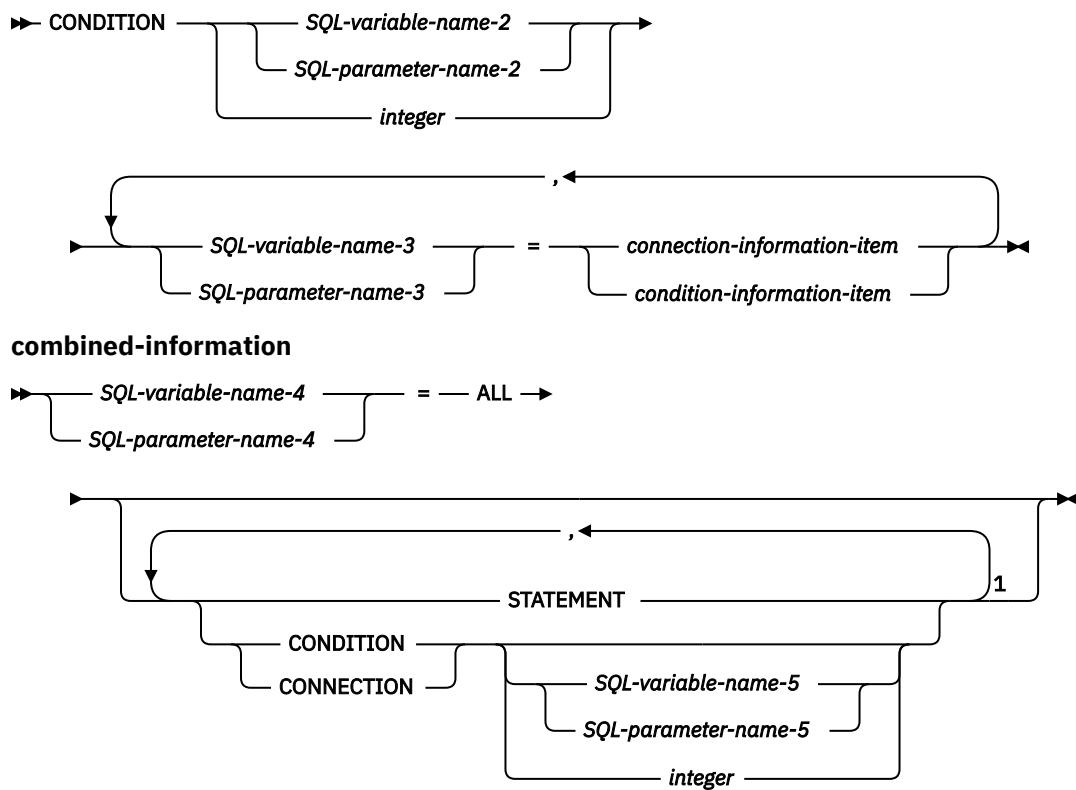

Syntax

statement-information

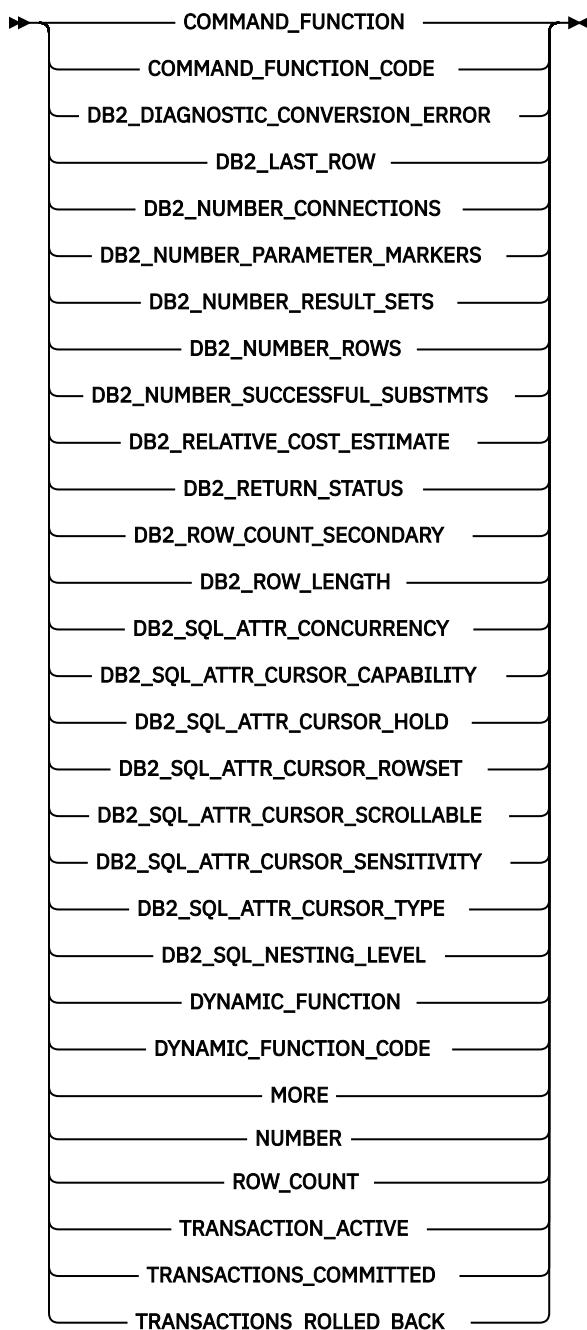

condition-information

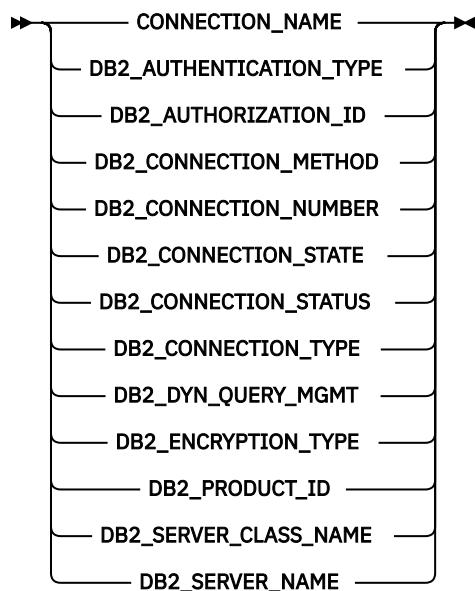

Notes:

¹ STATEMENT can only be specified once. If SQL-variable-name-5, SQL-parameter-name-5, or integer is not specified, CONDITION and CONNECTION can only be specified once.

Description

label

Specifies the label for the GET DIAGNOSTICS statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

CURRENT or STACKED

Specifies which diagnostics area to access.

CURRENT

Specifies to access the first diagnostics area. It corresponds to the previous SQL statement that was executed and that was not a GET DIAGNOSTICS statement. This is the default.

STACKED

Specifies to access the second diagnostics area. The second diagnostics area is only available within a handler. It corresponds to the previous SQL statement that was executed before the handler was entered and that was not a GET DIAGNOSTICS statement. If the GET DIAGNOSTICS statement is the first statement within a handler, then the first diagnostics area and the second diagnostics area contain the same diagnostics information.

statement-information

Returns information about the last SQL statement executed.

SQL-variable-name-1 or SQL-parameter-name-1

Identifies a variable described in the program in accordance with the rules for declaring SQL variables and SQL parameters. The data type of the SQL variable or SQL parameter must be compatible with the data type as specified in [Table 103 on page 1162](#) for the specified condition information item. The variable is assigned the value of the specified statement information item according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88. If the value is truncated when assigning it to the SQL variable or SQL parameter, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information , then the SQL variable or SQL parameter is set to a default value, based on its data type: 0 for an exact numeric diagnostic item, an empty string for a VARCHAR diagnostic item and blanks for a CHAR diagnostic item.

condition-information

Returns information about the condition or conditions that occurred when the last SQL statement was executed.

CONDITION SQL-variable-name-2 or SQL-parameter-name-2 or integer

Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic and so on. When the value is 1, the diagnostic information corresponds to the condition indicated by the SQLSTATE value returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). Values of 2 to n represent other conditions that were reported while executing the SQL statement. The value of 2 is the earliest condition that occurred, with each additional value happening later in time.

The variable specified must be declared in the program in accordance with the rules for declaring exact numeric variables with zero scale. It must not be a global variable. The value specified must not be less than one or greater than the number of available diagnostics.

SQL-variable-name-3 or SQL-parameter-name-3

Identifies a variable described in the program in accordance with the rules for declaring SQL variables or SQL parameters. The data type of the SQL variable or SQL parameter must be compatible with the data type as specified in [Table 103 on page 1162](#) for the specified condition information item. The SQL variable or SQL parameter is assigned the value of the specified condition information item according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88. If the value is truncated when assigning it to the SQL variable or SQL parameter, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information , then the SQL variable or SQL parameter is set to a default value, based on its data type: 0 for an exact numeric diagnostic item, an empty string for a VARCHAR diagnostic item and blanks for a CHAR diagnostic item.

combined-information

Returns multiple information items combined into one string.

If the GET DIAGNOSTICS statement is specified in an SQL function, SQL procedure, or trigger, the GET DIAGNOSTICS statement must be the first statement specified in the handler that will handle the error.

If information is wanted about a warning,

- If a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first statement specified in that handler.
- If a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

SQL-variable-name-4 or SQL-parameter-name-4

Identifies a variable described in the program in accordance with the rules for declaring SQL variables or SQL parameters. The data type of the SQL variable or SQL parameter must be VARCHAR. The SQL variable or SQL parameter is assigned according to the retrieval assignment rules described in “[Retrieval assignment](#)” on page 88. If the length of *SQL-variable-name-4* or *SQL-parameter-name-4* is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

ALL

Indicates that all diagnostic items that are set for the last SQL statement executed should be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form:

```
item-name=character-form-of-the-item-value;
```

The character form of a positive numeric value will not contain a leading plus sign (+) unless the item is RETURNED_SQLCODE. In this case, a leading plus sign (+) is added. For example:

```
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
```

Only items that contain diagnostic information are included in the string. There are also no entries in this string for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS and DB2_SQL_NESTING_LEVEL items.

STATEMENT

Indicates that all *statement-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. The format is the same as described above for the ALL option.

CONDITION

Indicates that *condition-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If *SQL-variable-name-5* or *SQL-parameter-name-5* or *integer* is specified, then the format is the same as described above for the ALL option. If *SQL-variable-name-5* or *SQL-parameter-name-5* or *integer* is not specified, then the format includes a condition number entry at the beginning of the information for that condition in the form:

```
CONDITION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED_SQLCODE=+100;  
CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

CONNECTION

Indicates that *connection-information-item* diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If *SQL-variable-name-5* or *SQL-parameter-name-5* or *integer* is specified, then the format is the same as described above for ALL. If *SQL-variable-name-5* or *SQL-parameter-name-5* or *integer* is not specified, then the format includes a connection number entry at the beginning of the information for that condition in the form:

```
CONNECTION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN07010;
```

SQL-variable-name-5 or SQL-parameter-name-5 or integer

Identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The SQL variable or SQL parameter specified must be described in the program in accordance with the rules for declaring integer SQL variables or SQL parameters. The value specified must not be less than one or greater than the number of available diagnostics.

statement-information-item

For a description of the *statement-information-items*, see “[statement-information-item](#)” on page [1151](#).

connection-information-item

For a description of the *connection-information-items*, see “[connection-information-item](#)” on page [1154](#).

condition-information-item

For a description of the *condition-information-items*, see “[condition-information-item](#)” on page [1155](#).

Notes

Effect of statement: The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

Considerations for the SQLCODE and SQLSTATE SQL variables: The GET DIAGNOSTICS statement changes the value of the SQLSTATE and SQLCODE SQL variables.

Case of return values: Values for identifiers in returned diagnostic items are not delimited and are case sensitive. For example, a table name of "abc" would be returned, simply as abc.

Data types for items: When a diagnostic item is assigned to a SQL variable or SQL parameter, the SQL variable or SQL parameter must be compatible with the data type of the diagnostic item. For more information, see [Table 103 on page 1162](#).

Keyword Synonym: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword EXCEPTION can be used as a synonym for CONDITION.
- The keyword RETURN_STATUS can be used as a synonym for DB2_RETURN_STATUS.

Example

Example 1:: In an SQL procedure, execute a GET DIAGNOSTICS statement to determine how many rows were updated.

```
CREATE PROCEDURE sqlprocg (IN deptnbr VARCHAR(3))
LANGUAGE SQL
BEGIN
  DECLARE SQLSTATE CHAR(5);
  DECLARE rcount INTEGER;
  UPDATE CORPDATA.PROJECT
    SET PRSTAFF = PRSTAFF + 1.5
   WHERE DEPTNO = deptnbr;
```

```

GET DIAGNOSTICS rcount = ROW_COUNT;
/* At this point, rcount contains the number of rows that were updated. */
END

```

Example 2:: Within an SQL procedure, handle the returned status value from the invocation of a stored procedure called TRYIT. TRYIT could use the RETURN statement to explicitly return a status value or a status value could be implicitly returned by the database manager. If the procedure is successful, it returns a value of zero.

```

CREATE PROCEDURE TESTIT ()
  LANGUAGE SQL
  A1: BEGIN
    DECLARE RETVAL INTEGER DEFAULT 0;
    ...
    CALL TRYIT
    GET DIAGNOSTICS RETVAL = RETURN_STATUS;
    IF RETVAL <> 0 THEN
      ...
      LEAVE A1;
    ELSE
      ...
    END IF;
  END A1

```

Example 3:: In an SQL procedure, execute a GET DIAGNOSTICS statement to retrieve the message text for an error.

```

CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER,
                           OUT divide_error VARCHAR(70) )
LANGUAGE SQL
BEGIN
  DECLARE CONTINUE HANLER FOR SQLEXCEPTION
  GET DIAGNOSTICS EXCEPTION 1
    divide_error = MESSAGE_TEXT;
  SET divide_result = numerator / denominator;
END;

```

GOTO statement

The GOTO statement branches to a user-defined label within an SQL function, SQL procedure, or SQL trigger.

Syntax

►  GOTO — *label2* ►

label1:

Description

label1

Specifies the label for the GOTO statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

label2

Specifies the labeled statement where processing is to continue. The labeled statement and the GOTO statement must both be in the same scope:

- If the GOTO statement is defined in a FOR statement, *label2* must be defined inside the same FOR statement, excluding a nested FOR statement or nested compound statement.

- If the GOTO statement is defined outside a FOR statement, *label2* must not be defined within a FOR statement or nested compound statement.
- If the GOTO statement is defined in a condition handler, *label2* must be defined inside the same handler.
- If the GOTO statement is defined outside a condition handler, *label2* must not be defined within a condition handler.

If *label2* is not defined within a scope that the GOTO statement can reach, an error is returned.

Notes

Using a GOTO statement: It is recommended that the GOTO statement be used sparingly. This statement interferes with normal sequence of processing SQL statements, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

Effect on open cursors: When a GOTO statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the GOTO statement are closed, unless they are declared to return result sets or unless *ENDACTGRP is specified.

Effect on ATOMIC compound statements: When a GOTO statement transfers control out of an ATOMIC compound statement, the savepoint that was implicitly started when the ATOMIC compound statement was entered is released.

Considerations for SQLSTATE and SQLCODE variables: The GOTO statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the GOTO statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that GOTO statement.

Example

In the following statement, the parameters *rating* and *v_empno* are passed in to the procedure. The time in service is returned as a date duration in output parameter *return_parm*. If the time in service with the company is less than 6 months, the GOTO statement transfers control to the end of the procedure and *new_salary* is left unchanged.

```

CREATE PROCEDURE adjust_salary
  (IN v_empno CHAR(6),
   IN rating INTEGER,
   OUT return_parm DECIMAL(8,2))
LANGUAGE SQL
MODIFIES SQL DATA
BEGIN
  DECLARE new_salary DECIMAL(9,2);
  DECLARE service DECIMAL(8,2);
  SELECT salary, CURRENT_DATE - hiredate
    INTO new_salary, service
   FROM employee
  WHERE empno = v_empno;
  IF service < 600
    THEN GOTO exit1;
  END IF;
  IF rating = 1
    THEN SET new_salary = new_salary + (new_salary * .10);
  ELSEIF rating = 2
    THEN SET new_salary = new_salary + (new_salary * .05);
  END IF;
  UPDATE employee
    SET salary = new_salary
   WHERE empno = v_empno;

  EXIT1: SET return_parm = service;
END

```

IF statement

The IF statement executes different sets of SQL statements based on the result of search conditions.

Syntax

Description

label

Specifies the label for the IF statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

search-condition

Specifies the *search-condition* for which an SQL statement should be executed. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

SQL-procedure-statement

Specifies an SQL statement to execute if the preceding *search-condition* is true.

Notes

Considerations for SQLSTATE and SQLCODE SQL variables: When the first *SQL-procedure-statement* in the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the *search-conditions* of that IF statement. If an IF statement does not include an ELSE clause and none of the *search-conditions* evaluate to true, then when the statement that follows the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement.

Example

The following SQL procedure accepts two IN parameters: an employee number and an employee rating. Depending on the value of *rating*, the employee table is updated with new values in the salary and bonus columns.

```
CREATE PROCEDURE UPDATE_SALARY_IF
  (IN employee_number CHAR(6), INOUT rating SMALLINT)
  LANGUAGE SQL
  MODIFIES SQL DATA
  BEGIN
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE EXIT HANDLER FOR not_found
```

```

    SET rating = -1;
  IF rating = 1
    THEN UPDATE employee
      SET salary = salary * 1.10, bonus = 1000
      WHERE empno = employee_number;
  ELSEIF rating = 2
    THEN UPDATE employee
      SET salary = salary * 1.05, bonus = 500
      WHERE empno = employee_number;
  ELSE UPDATE employee
    SET salary = salary * 1.03, bonus = 0
    WHERE empno = employee_number;
  END IF;
END

```

INCLUDE statement

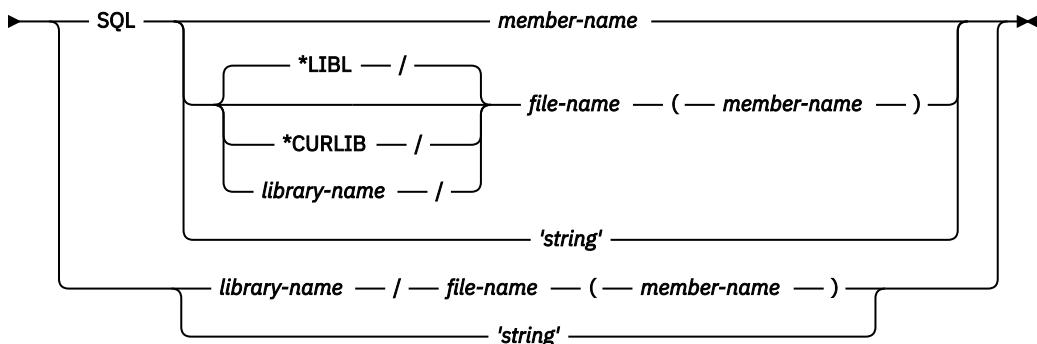

The INCLUDE statement inserts application code, including declarations and statements, into an SQL routine body. The included code can either be SQL code that is immediately added to the routine definition or ILE C code to be added during the create of the SQL procedure, SQL function, or SQL trigger.

Authorization

The authorization ID of the statement must have the system authorities *OBJOPR and *READ on the file that contains the member.

Syntax

►► INCLUDE ►►

Description

The INCLUDE statement must be specified at a point in the source where the included source statements are syntactically acceptable. Both forms of the INCLUDE statement can be specified as an *SQL-procedure-statement* within the body of a *compound-statement*. An INCLUDE SQL statement can also be specified within the declarations and handlers of a *compound-statement*. There is no limit to the number of includes that can be specified in one statement, but the included source cannot contain an embedded include.

SQL

The included source contains only SQL syntax that is allowed in an *SQL-routine-body* or *SQL-trigger-body*. These statements will be expanded inline as part of the *SQL-routine-body* or *SQL-trigger-body*. They will be processed as if they are directly part of the statement text for the statement. The statement text saved for the SQL procedure, function, or trigger will contain this included source. If the QSYS2.GENERATE_SQL procedure is used, the generated source will show the expanded SQL statements wherever an INCLUDE SQL was used.

member-name

Identifies a member to be included within the SQL procedure, SQL function, or SQL trigger. The source file and library will be determined using the INCFILE option on the SET OPTION statement. For more information, see “[SET OPTION](#)” on page 1303.

file-name (member-name)

Identifies a source file and member to be included within the SQL procedure, SQL function, or SQL trigger. The library containing the source file is specified in one of these ways:

***LIBL**

All libraries in the job's library list are searched until the first match is found. This is the default.

***CURLIB**

The current library for the job is searched. If no library is specified as the current library for the job, QGPL is used.

library-name

Identifies the name of the library.

'string'

Identifies a source stream file to be included. The string will be handled as a normal SQL string literal; the source stream file rules for escaping characters will not be followed. No suffix will be appended to the string.

SQL not specified

The included source contains only ILE C language statements or embedded SQL statements prefixed with EXEC SQL. A corresponding EXEC SQL INCLUDE statement will be generated as part of the program source that is generated for this SQL procedure, SQL function, or SQL trigger.

If the include requires additional service programs to be bound during the creation of the procedure, function, or trigger, you can use the BINDOPT option on the SET OPTION statement to add a BNDSRVPGM parameter to reference exports found in other service programs. For more information, see “[SET OPTION](#)” on page 1303.

library-name / file-name (member-name)

Specifies the fully qualified source file and member containing ILE C language statements to be included during the creation of the SQL procedure, SQL function, or SQL trigger.

'string'

Specifies the complete path for a source stream file containing ILE C language statements to be included during the creation of the SQL procedure, SQL function, or SQL trigger.

Notes

CCSID considerations: If the CCSID of the SQL statement is different from the CCSID of the source for the INCLUDE statement, the INCLUDE source is converted to the CCSID of the SQL statement.

Source considerations: The source of a C include should not exceed 160 source columns. Anything beyond that position will be truncated.

String literals in an SQL include cannot be longer than the width of the embedding source.

The source of an SQL include should contain complete SQL statements. Although not enforced, unpredictable results may occur if this rule is violated.

SQL trigger consideration: When an SQL trigger uses the INCLUDE statement to include ILE C, any operation that requires the trigger program to be rebuilt has a runtime dependency on the include file. If the trigger program is not found, it can be automatically rebuilt by the database when the trigger is fired, when the table is copied, or when the table is restored. If the include file is not available, the trigger will not create and any function requiring the trigger will fail.

Examples

- Use the INCLUDE statement to embed a common condition handler in an SQL function.

```
CREATE FUNCTION H1 ()
RETURNS INT
DETERMINISTIC
NO EXTERNAL ACTION
NOT FENCED
```

```

BEGIN
  DECLARE RES INT;
  INCLUDE SQL SQLINCLUDE(COMMONCOND);

  SET RES = AFUNCTION();
  RETURN RES;
END;

```

COMMONCOND in file SQLINCLUDE in the library list contains the following. The condition handler calls an SQL procedure named ERR_PROC for a specific not found condition. As part of the message handling, it uses the ROUTINE_SCHEMA and ROUTINE_SPECIFIC_NAME built-in global variables to indicate the source of the error.

```

DECLARE NO_FUNC CONDITION FOR SQLSTATE '42704';
DECLARE CONTINUE HANDLER FOR NO_FUNC
BEGIN
  CALL ERR_PROC(SYSIBM.ROUTINE_SCHEMA CONCAT '.' CONCAT
                SYSIBM.ROUTINE_SPECIFIC_NAME CONCAT
                ': Function not found');
END;

```

- Use the INCLUDE statement to embed a call to a C function. It will use the Qp0zLprintf interface to print the input parameter.

```

CREATE PROCEDURE LPRINTF(P1 VARCHAR(1000))
BEGIN
  IF P1 IS NOT NULL THEN
    INCLUDE QGPL/CINCLUDE(MYLPRINTF);
  END IF;
END;

```

Member MYLPRINTF in file CINCLUDE in library QGPL contains the following code. Note that this include has a reference to the function's input parameter. You need to examine the generated C code to determine what the names are.

```

{
  /* declare prototype for Qp0zLprintf */
  extern int Qp0zLprintf (char *format, ...);

  /* print input parameter to job log */
  Qp0zLprintf("%.*s\n", LPRINTF.P1.LEN, LPRINTF.P1.DAT);
}

```

ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

Syntax

```

    ➤ [brace] label: : ➤
ITERATE — target-label ➤
[brace]

```

Description

label

Specifies the label for the ITERATE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

target-label

Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the flow of control is passed. *target-label* must be defined as a label for a FOR, LOOP, REPEAT, or WHILE statement. The ITERATE statement must be in that FOR, LOOP, REPEAT, or WHILE statement, or in the block of code that is directly or indirectly nested within that statement, subject to the following restrictions:

- If the ITERATE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the ITERATE statement is not in a condition handler, *target-label* must not be defined in a condition handler.
- If the ITERATE statement is in a FOR statement, *target-label* must be that label on that FOR statement, or the label must be defined inside that FOR statement.

Notes

Considerations for SQLSTATE and SQLCODE variables: The ITERATE statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the ITERATE statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that ITERATE statement.

Example

This example uses a cursor to return information for a new department. If the *not_found* condition handler was invoked, the flow of control passes out of the loop. If the value of *v_dept* is 'D11', an ITERATE statement passes the flow of control back to the top of the LOOP statement. Otherwise, a new row is inserted into the DEPARTMENT table.

```

CREATE PROCEDURE ITERATOR ()
LANGUAGE SQL
MODIFIES SQL DATA
BEGIN
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
        SELECT deptno,deptname,admdept
        FROM department
        ORDER BY deptno;
    DECLARE CONTINUE HANDLER FOR not_found
        SET at_end = 1;
    OPEN c1;
    ins_loop:
    LOOP
        FETCH c1 INTO v_dept, v_deptname, v_admdept;
        IF at_end = 1 THEN
            LEAVE ins_loop;
        ELSEIF v_dept = 'D11' THEN
            ITERATE ins_loop;
        END IF;
        INSERT INTO department (deptno,deptname,admdept)
            VALUES('NEW', v_deptname, v_admdept);
    END LOOP;
    CLOSE c1;
END

```

LEAVE statement

The LEAVE statement continues execution by leaving a block or loop.

Syntax

```

→ { label1: } LEAVE — label2 →

```

Description

label1

Specifies the label for the LEAVE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

label2

Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit.

The LEAVE statement cannot be used to leave a handler.

Notes

Effect on open cursors: When a LEAVE statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the LEAVE statement are closed, unless they are declared to return result sets or unless *ENDACTGRP is specified.

Considerations for SQLSTATE and SQLCODE variables: The LEAVE statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the LEAVE statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that LEAVE statement.

Examples

The example contains a loop that fetches data for cursor c1. If the value of SQL variable *at_end* is not zero, the LEAVE statement transfers control out of the loop.

```
CREATE PROCEDURE LEAVE_LOOP (OUT COUNTER INTEGER)
  LANGUAGE SQL
BEGIN
  DECLARE v_counter INTEGER;
  DECLARE v_firstname VARCHAR(12);
  DECLARE v_midinit CHAR(1);
  DECLARE v_lastname VARCHAR(15);
  DECLARE at_end SMALLINT DEFAULT 0;
  DECLARE not_found CONDITION FOR SQLSTATE '02000';
  DECLARE c1 CURSOR FOR
    SELECT firstname, midinit, lastname
    FROM employee;
  DECLARE CONTINUE HANDLER FOR not_found
    SET at_end = 1;
  SET v_counter = 0;
  OPEN c1;
  fetch_loop:
  LOOP
    FETCH c1 INTO v_firstname, v_midinit, v_lastname;
    IF at_end <> 0 THEN
      LEAVE fetch_loop;
    END IF;
    SET v_counter = v_counter + 1;
  END LOOP fetch_loop;
  SET counter = v_counter;
  CLOSE c1;
END
```

LOOP statement

The LOOP statement repeats the execution of a statement or a group of statements.

Syntax

Description

label

Specifies the label for the LOOP statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see [“References to SQL labels” on page 1361](#).

SQL-procedure statement

Specifies an SQL statement to be executed in the loop

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the LOOP statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for SQLSTATE and SQLCODE variables: Prior to executing the first *SQL-procedure statement* within that LOOP statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the LOOP statement. If the loop is terminated with a GOTO or a LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. When the LOOP statement iterates, the SQLSTATE and SQLCODE values reflect the result of the last SQL statement executed within the LOOP statement.

Examples

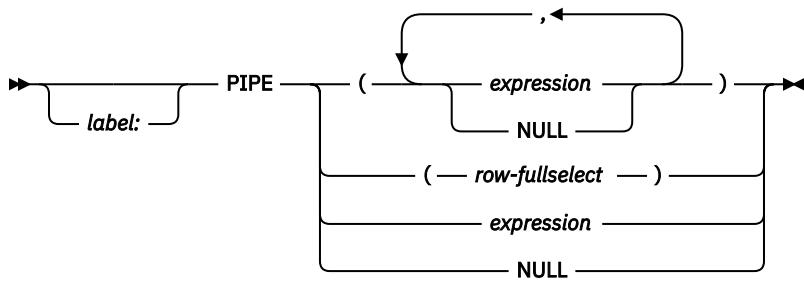

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter *counter* is incremented and the value of *v_midinit* is checked to ensure that the value is not a single space (' '). If *v_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

```
CREATE PROCEDURE LOOP_UNTIL_SPACE (OUT COUNTER INTEGER)
LANGUAGE SQL
BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
        SELECT firstname, midinit, lastname
        FROM employee;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
        SET counter = -1;
    OPEN c1;
    fetch_loop:
    LOOP
        FETCH c1 INTO v_firstname, v_midinit, v_lastname;
        IF v_midinit = ' ' THEN
            LEAVE fetch_loop;
        END IF;
        SET v_counter = v_counter + 1;
    END LOOP fetch_loop;
    SET counter = v_counter;
    CLOSE c1;
END
```

PIPE statement

The PIPE statement returns one row from a table function. An SQL table function that uses a PIPE statement is referred to as a pipelined function.

Syntax

Description

label

Specifies the label for the PIPE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see [“References to SQL labels” on page 1361](#).

(expression, ...)

Specifies a row value is returned from the function. The number of expressions or NULL keywords in the list must match the number of columns in the function result. The data types of each expression must be assignable to the data type of the corresponding column defined for the function result, using the storage assignment rules as described in [“Assignments and comparisons” on page 83](#).

row-fullselect

Specifies a fullselect that returns a single row. The number of columns in the fullselect must match the number of columns in the function result. The data types of the result table columns of the fullselect must be assignable to the data types of the columns defined for the function result, using the storage assignment rules as described in [“Assignments and comparisons” on page 83](#). If the result of the row fullselect is no rows, a null value is returned for each column. An error is returned if there is more than one row in the result.

expression

Specifies a scalar value is returned from the function. The table function must return a single column and the value of the expression must be assignable to that column.

NULL

Specifies that a null value is returned from the function. If there is more than one result column, a null value is returned for each column.

Example

Use a PIPE statement to return rows from an SQL table function.

```
CREATE FUNCTION TRANSFORM() RETURNS TABLE ( EMPLOYEE_NAME CHAR(20), UNIQUE# INT )
BEGIN
  DECLARE EMPNAME VARCHAR(15);
  DECLARE MYRECNUM INTEGER DEFAULT 1;
  DECLARE AT_END INTEGER DEFAULT 0;
  DECLARE EMP_CURSOR CURSOR FOR SELECT lastname FROM employee;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000'
    SET AT_END = 1;

  OPEN EMP_CURSOR;
  MYLOOP: LOOP
    FETCH EMP_CURSOR INTO EMPNAME;
    IF AT_END = 1 THEN
      LEAVE MYLOOP;
    END IF;
  END LOOP;
```

```

END IF;
PIPE (EMPNAME, MYRECNUM); -- return single row
SET MYRECNUM = MYRECNUM + 1;
END LOOP;

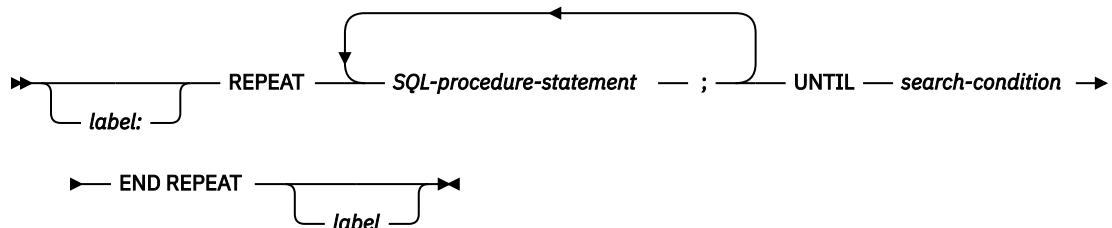

CLOSE EMP_CURSOR;
RETURN;
END;

```

REPEAT statement

The REPEAT statement executes a statement or group of statements until a search condition is true.

Syntax

Description

label

Specifies the label for the REPEAT statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

SQL-procedure-statement

Specifies an SQL statement to be executed in the REPEAT loop.

search-condition

The *search-condition* is evaluated after each execution of the REPEAT loop. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the looping continues.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the REPEAT statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for SQLSTATE and SQLCODE SQL variables: With each iteration of the REPEAT statement, the SQLSTATE and SQLCODE SQL variables are cleared prior to executing the first *SQL-procedure-statement* within the REPEAT statement. At the beginning of the first iteration of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the REPEAT statement. At the beginning of iterations 2 through n of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END REPEAT of the REPEAT statement completes, the SQLSTATE and SQLCODE values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement.

Example

A REPEAT statement fetches rows from a table until the *not_found* condition handler is invoked.

```

CREATE PROCEDURE REPEAT_STMT (OUT COUNTER INTEGER)
LANGUAGE SQL
BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstname VARCHAR(12);

```

```

DECLARE v_midinit CHAR(1);
DECLARE v_lastname VARCHAR(15);
DECLARE at_end SMALLINT DEFAULT 0;
DECLARE not_found CONDITION FOR SQLSTATE '02000';
DECLARE c1 CURSOR FOR
  SELECT firstname, midinit, lastname
    FROM employee;
DECLARE CONTINUE HANDLER FOR not_found
  SET at_end = 1;
OPEN c1;
fetch_loop:
REPEAT
  FETCH c1 INTO v_firstname, v_midinit, v_lastname;
  SET v_counter = v_counter + 1;
  UNTIL at_end > 0
END REPEAT fetch_loop;
SET counter = v_counter;
CLOSE c1;
END

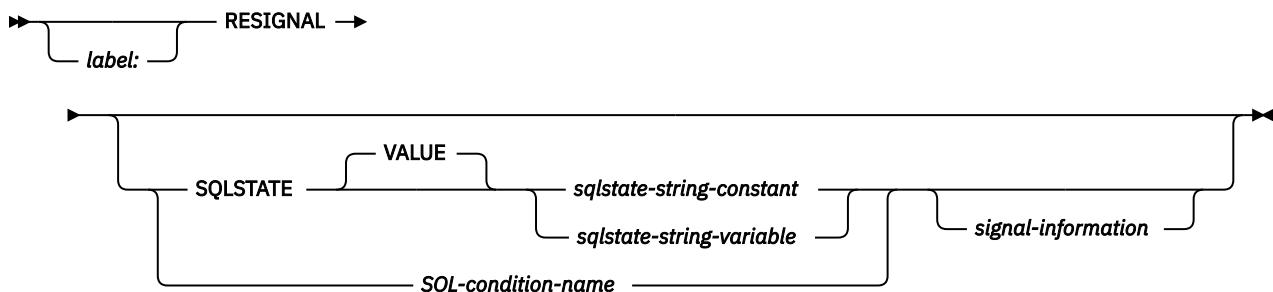

```

RESIGNAL statement

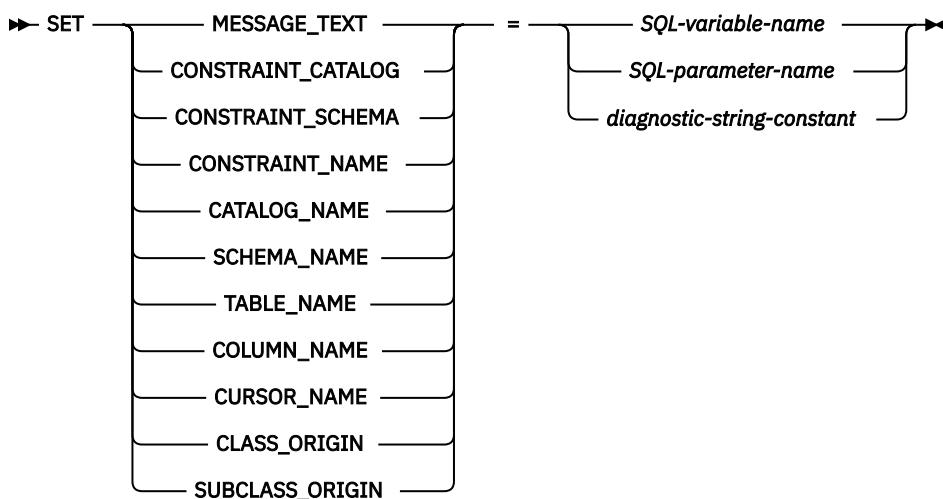

The RESIGNAL statement is used within a condition handler to re-raise the current condition, or raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned, along with optional message text.

Issuing the RESIGNAL statement without an operand causes the current condition to be passed outwards.

Syntax

signal-information

Description

label

Specifies the label for the RESIGNAL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

SQLSTATE VALUE

Specifies the SQLSTATE that will be resigned. Any valid SQLSTATE value can be used. The specified value must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

sqlstate-string-constant

The *sqlstate-string-constant* must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The *sqlstate-string-variable* must be a character or Unicode graphic variable. The actual length of the contents of the *sqlstate-string-variable* must be 5.

SQL-condition-name

Specifies the name of the condition that will be returned. The *SQL-condition-name* must be declared within the *compound-statement*.

SET

Introduces the assignment of values to *condition-information-items*. The *condition-information-item* values can be accessed using the GET DIAGNOSTICS statement. The only *condition-information-item* that can be accessed in the SQLCA is MESSAGE_TEXT.

MESSAGE_TEXT

Specifies a string that describes the error or warning.

If an SQLCA is used,

- the string is returned in the SQLERRMC field of the SQLCA
- if the actual length of the string is longer than 1000 bytes, it is truncated without a warning.

CONSTRAINT_CATALOG

Specifies a string that indicates the name of the database that contains a constraint related to the signaled error or warning.

CONSTRAINT_SCHEMA

Specifies a string that indicates the name of the schema that contains a constraint related to the signaled error or warning.

CONSTRAINT_NAME

Specifies a string that indicates the name of a constraint related to the signaled error or warning.

CATALOG_NAME

Specifies a string that indicates the name of the database that contains a table or view related to the signaled error or warning.

SCHEMA_NAME

Specifies a string that indicates the name of the schema that contains a table or view related to the signaled error or warning.

TABLE_NAME

Specifies a string that indicates the name of a table or view related to the signaled error or warning.

COLUMN_NAME

Specifies a string that indicates the name of a column in the table or view related to the signaled error or warning.

CURSOR_NAME

Specifies a string that indicates the name of a cursor related to the signaled error or warning.

CLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE class related to the signaled error or warning.

SUBCLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE subclass related to the signaled error or warning.

SQL-variable-name

Identifies an SQL variable declared within the *compound-statement*, that contains the value to be assigned to the *condition-information-item*. The SQL variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

SQL-parameter-name

Identifies an SQL parameter declared within the *compound-statement*, that contains the value to be assigned to the *condition-information-item*. The SQL parameter must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

diagnostic-string-constant

Specifies a character string constant that contains the value to be assigned to the *condition-information-item*.

Notes

SQLSTATE values: Any valid SQLSTATE value can be used in the RESIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

For more information about SQLSTATEs, see the [SQL Messages and Codes](#) topic collection.

Assignment: When the RESIGNAL statement is executed, the value of each of the specified *string-constants* and *variables* is assigned to the corresponding *condition-information-item*. However, if the length of a *string-constant* or *variable* is longer than the maximum length of the corresponding *condition-information-item*, it is truncated without a warning. For details on the assignment rules, see “[Assignments and comparisons](#)” on page 83. For details on the maximum length of specific *condition-information-items*, see “[GET DIAGNOSTICS](#)” on page 1144.

Processing a RESIGNAL statement:

- If the RESIGNAL statement is specified without a SQLSTATE clause or a *SQL-condition-name*, the SQL function, SQL procedure, or SQL trigger ressignals the identical condition that invoked the handler and the SQLCODE is not changed.
- When a RESIGNAL statement is issued and an SQLSTATE or *SQL-condition-name* is specified, the SQLCODE is based on the SQLSTATE value as follows:
 - If the specified SQLSTATE class is either '01' or '02', a warning or not found is signaled and the SQLCODE is set to +438.
 - Otherwise, an exception is returned and the SQLCODE is set to -438.

If the SQLSTATE or condition indicates that an exception is signaled (SQLSTATE class other than '01' or '02'):,

- If a handler exists in the same compound statement as the RESIGNAL statement, and the *compound-statement* contains a handler for SQUEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.

- If the *compound-statement* is nested and an outer level *compound-statement* has a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') or not found (SQLSTATE class '02') is signaled:

- If a handler exists in the same compound statement as the RESIGNAL statement, and the *compound-statement* contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is handled and control is transferred to that handler.
- If the *compound-statement* is nested and an outer level compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is not handled and processing continues with the next statement.
- Otherwise, the warning is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The RESIGNAL statement might modify the contents of the current diagnostics area. If an SQLSTATE or *SQL-condition-name* is specified as part of the RESIGNAL statement, the RESIGNAL statement starts with a clear of the diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or *SQL-condition-name*. If any *signal-information* is specified, the corresponding items in the condition area are assigned the specified values. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or *SQL-condition-name*.

Example

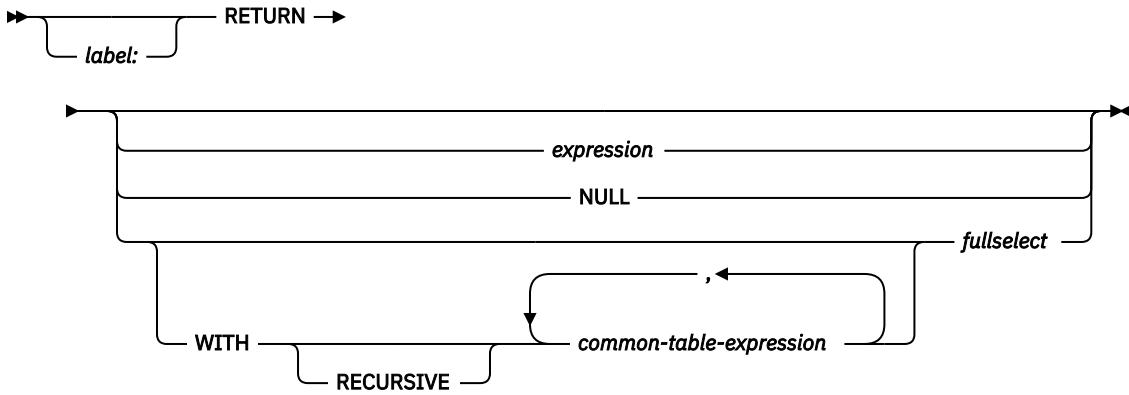

This example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE value to the client application.

```
CREATE PROCEDURE divide ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER )
LANGUAGE SQL
BEGIN
  DECLARE overflow CONDITION FOR '22003';
  DECLARE CONTINUE HANDLER FOR overflow
    RESIGNAL SQLSTATE '22375';
  IF denominator = 0 THEN
    SIGNAL overflow;
  ELSE
    SET divide_result = numerator / denominator;
  END IF;
END
```

RETURN statement

The RETURN statement returns from a routine. For SQL scalar functions, it returns the result of the function. For SQL non-pipelined table functions, it returns a table as the result of the function. For SQL pipelined table functions, it indicates the end of the result table has been reached. For an SQL procedure, it optionally returns an integer status value.

Syntax

Description

label

Specifies the label for the RETURN statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

expression

Specifies a value that is returned from the routine:

- If the routine is a scalar function, the data type of the result must be assignable to the data type defined for the function result, using the storage assignment rules as described in “[Assignments and comparisons](#)” on page 83. An aggregate function, or user-defined function that is sourced on an aggregate function must not be specified for a RETURN statement in an SQL scalar function.
- If the routine is a table function, a scalar expression (other than a scalar fullselect) cannot be specified.
- If the routine is a procedure, the data type of *expression* must be INTEGER. If the *expression* evaluates to the null value, a value of zero is returned.

NULL

Specifies that the null value is returned from the routine.

- If the routine is a scalar function, the null value is returned.
- If the routine is a table function, NULL must not be specified.
- If the routine is a procedure, NULL must not be specified.

WITH common-table-expression

Specifies one or more *common table expressions* to be used in the fullselect.

fullselect

Specifies the row or rows to be returned for the routine.

- If the routine is a scalar function, the fullselect must return one column and, at most, one row. The data type of the result column must be assignable to the data type defined for the function result, using the storage assignment rules as described in “[Assignments and comparisons](#)” on page 83.
- If the routine is a table function, the fullselect can return zero or more rows with one or more columns. The number of columns in the fullselect must match the number of columns in the function result. In addition, the data types of the result table columns of the fullselect must be assignable to the data types of the columns defined for the function result, using the storage assignment rules as described in “[Assignments and comparisons](#)” on page 83.
- If the routine is a procedure, fullselect must not be specified.

Notes

Returning from a table function:

- The last statement executed in the *SQL-routine-body* must be a RETURN statement.
- For a non-pipelined table function, the RETURN statement indicates the rows to be returned. Exactly one RETURN statement must be specified and it must contain a *fullselect*.
- For a pipelined table function, one or more RETURN statements must be specified and they must contain no return values.

Returning from a procedure:

- If a RETURN statement with a specified return value is used to return from a procedure then the SQLCODE, SQLSTATE, and message length in the SQLCA or diagnostics area are initialized to zeros, and message text is set to blanks. An error is not returned to the caller.
- If a RETURN statement is not used to return from a procedure or if a value is not specified on the RETURN statement,
 - if the procedure returns with an SQLCODE that is greater than or equal to zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of 0
 - if the procedure returns with an SQLCODE that is less than zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of -1.
- When a value is returned from a procedure, the caller may access the value using:
 - the GET DIAGNOSTICS statement to retrieve the DB2_RETURN_STATUS when the SQL procedure was called from another SQL procedure
 - the parameter bound for the return value parameter marker in the escape clause CALL syntax (? =CALL...) in a ODBC or JDBC application
 - directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqlerrd[0] when the SQLCODE is not less than zero. When the SQLCODE is less than zero, the sqlerrd[0] value is not set and the application should assume a return status value of -1.

RETURN restrictions:

- RETURN is not allowed in SQL triggers.
- In a compound(dynamic) statement, RETURN cannot specify a return value.

Example

Example 1: Use a RETURN statement to return from an SQL procedure with a status value of zero if successful, and -200 if not.

```
BEGIN
  ...
  GOTO fail;
  ...
  success: RETURN 0
  fail: RETURN -200
...
END
```

Example 2: Define a scalar function that returns the tangent of a value using the existing sine and cosine functions.

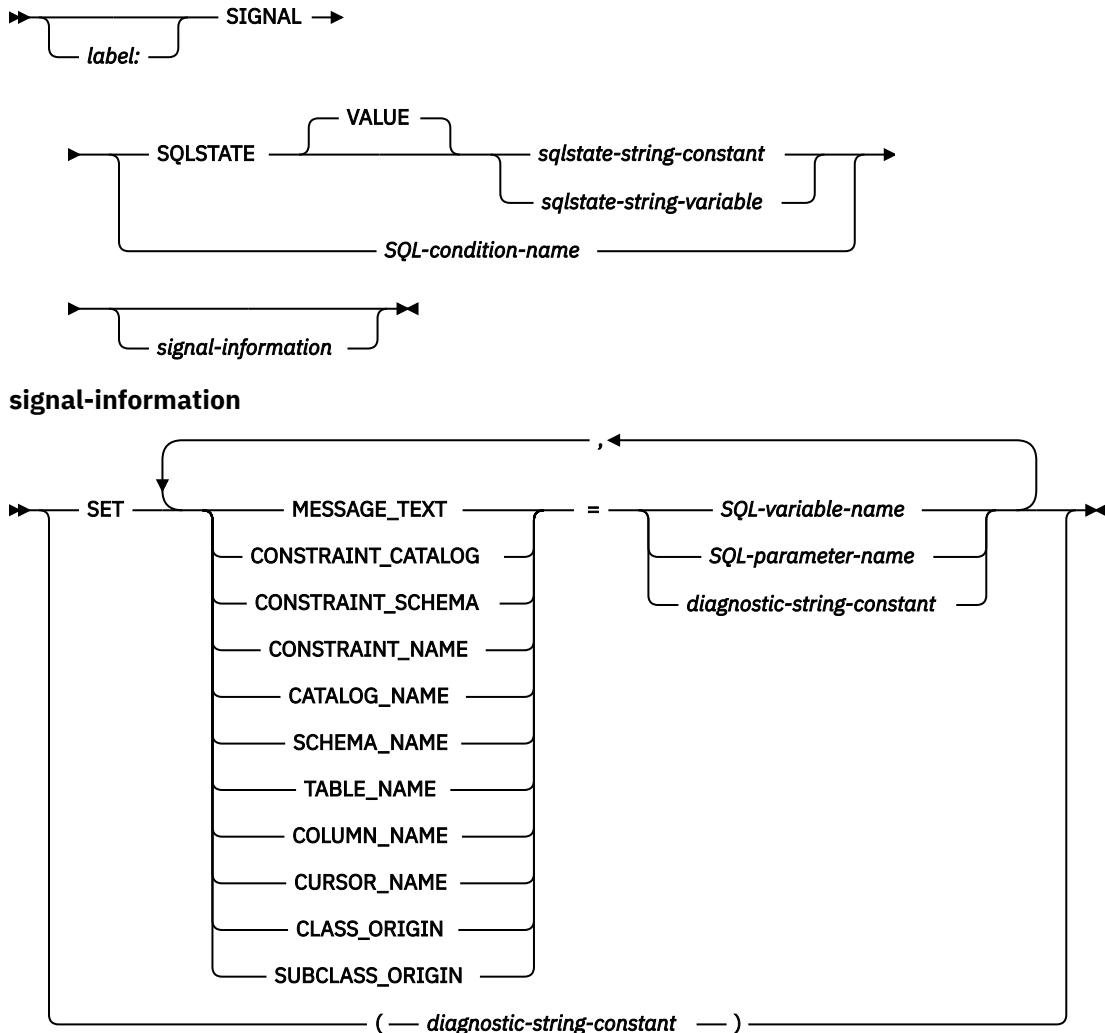

```
CREATE FUNCTION mytan (x DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(x)/COS(x)
```

SIGNAL statement

The SIGNAL statement signals an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE and optional *condition-information-items*. The syntax of SIGNAL in an SQL function, SQL procedure, or SQL trigger is similar to what is supported as a SIGNAL statement in other contexts.

See “[SIGNAL](#)” on page 1336 for details.

Syntax

Description

label

Specifies the label for the SIGNAL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

SQLSTATE VALUE

Specifies the SQLSTATE that will be signalled. The specified value must not be null and must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').

- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

sqlstate-string-constant

The *sqlstate-string-constant* must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The *sqlstate-string-variable* must be a character or Unicode graphic variable. The actual length of the contents of the *variable* must be 5.

SQL-condition-name

Specifies the name of the condition that will be signaled. The *SQL-condition-name* must be declared within the *compound-statement*.

SET

Introduces the assignment of values to *condition-information-items*. The *condition-information-item* values can be accessed using the GET DIAGNOSTICS statement. The only *condition-information-item* that can be accessed in the SQLCA is MESSAGE_TEXT.

MESSAGE_TEXT

Specifies a string that describes the error or warning.

If an SQLCA is used,

- the string is returned in the SQLERRMC field of the SQLCA
- if the actual length of the string is longer than 1000 bytes, it is truncated without a warning.

CONSTRAINT_CATALOG

Specifies a string that indicates the name of the database that contains a constraint related to the signaled error or warning.

CONSTRAINT_SCHEMA

Specifies a string that indicates the name of the schema that contains a constraint related to the signaled error or warning.

CONSTRAINT_NAME

Specifies a string that indicates the name of a constraint related to the signaled error or warning.

CATALOG_NAME

Specifies a string that indicates the name of the database that contains a table or view related to the signaled error or warning.

SCHEMA_NAME

Specifies a string that indicates the name of the schema that contains a table or view related to the signaled error or warning.

TABLE_NAME

Specifies a string that indicates the name of a table or view related to the signaled error or warning.

COLUMN_NAME

Specifies a string that indicates the name of a column in the table or view related to the signaled error or warning.

CURSOR_NAME

Specifies a string that indicates the name of a cursor related to the signaled error or warning.

CLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE class related to the signaled error or warning.

SUBCLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE subclass related to the signaled error or warning.

SQL-variable-name

Identifies an SQL variable declared within the *compound-statement*, that contains the value to be assigned to the *condition-information-item*. The SQL variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

SQL-parameter-name

Identifies an SQL parameter declared within the *compound-statement*, that contains the value to be assigned to the *condition-information-item*. The SQL parameter must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

diagnostic-string-constant

Specifies a character string constant that contains the value to be assigned to the *condition-information-item*.

(*diagnostic-string-constant*)

Specifies a character string constant that contains the message text.

This form is only allowed in the triggered action of a CREATE TRIGGER statement.

To conform with the ANSI and ISO standards, this form should not be used. It is provided for compatibility with other products.

Notes

SQLSTATE values: Any valid SQLSTATE value can be used in the SIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

For more information about SQLSTATEs, see the [SQL Messages and Codes](#) topic collection.

Assignment: When the SIGNAL statement is executed, the value of each of the specified *string-constants* and *variables* is assigned to the corresponding *condition-information-item*. However, if the length of a *string-constant* or *variable* is longer than the maximum length of the corresponding *condition-information-item*, it is truncated without a warning. For details on the assignment rules, see “[Assignments and comparisons](#)” on page 83. For details on the maximum length of specific *condition-information-items*, see “[GET DIAGNOSTICS](#)” on page 1144.

Processing a SIGNAL statement: When a SIGNAL statement is issued, the SQLCODE returned in the SQLCA is based on the SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not found is signaled and the SQLCODE is set to +438.
- Otherwise, an exception is signaled and the SQLCODE is set to -438.

If the SQLSTATE or condition indicates that an exception (SQLSTATE class other than '01' or '02') is signaled,

- If a handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- If the *compound-statement* is nested and an outer level *compound-statement* has a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') or not found (SQLSTATE class '02') is signaled,

- If a handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the

SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is handled and control is transferred to that handler.

- If the *compound-statement* is nested and an outer level compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is not handled and processing continues with the next statement.
- Otherwise, the warning is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The SIGNAL statement starts with a clear of the diagnostics area and then sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or *SQL-condition-name*. If any *signal-information* is specified, the corresponding items in the condition area are assigned the specified values. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or *SQL-condition-name*.

Example

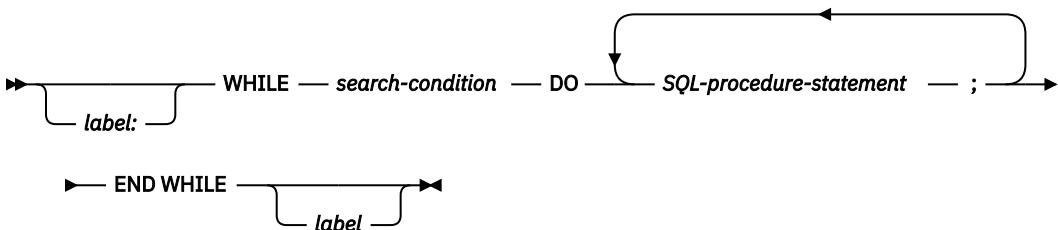

An SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```
CREATE PROCEDURE SUBMIT_ORDER
  (IN ONUM INTEGER, IN CNUM INTEGER,
   IN PNUM INTEGER, IN QNUM INTEGER)
  LANGUAGE SQL
  MODIFIES SQL DATA
BEGIN
  DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
    SIGNAL SQLSTATE '75002'
    SET MESSAGE_TEXT = 'Customer number is not known';
  INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
    VALUES (ONUM, CNUM, PNUM, QNUM);
END
```

WHILE statement

The WHILE statement repeats the execution of a statement while a specified condition is true.

Syntax

Description

label

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “[References to SQL labels](#)” on page 1361.

search-condition

Specifies a condition that is evaluated before each execution of the WHILE loop. If the condition is true, the *SQL-procedure-statements* in the WHILE loop are executed.

SQL-procedure-statement

Specifies an SQL statement or statements to execute within the WHILE loop.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the WHILE statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for SQLSTATE and SQLCODE SQL variables: With each iteration of the WHILE statement, when the first *SQL-procedure-statement* is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search condition of that WHILE statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END WHILE of the WHILE statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating the search condition of that WHILE statement.

Example

This example uses a WHILE statement to iterate through FETCH and SET statements. While the value of SQL variable *v_counter* is less than half of number of employees in the department identified by the IN parameter *deptNumber*, the WHILE statement continues to perform the FETCH and SET statements. When the condition is no longer true, the flow of control leaves the WHILE statement and closes the cursor.

```
CREATE PROCEDURE dept_median
  (IN deptNumber SMALLINT,
   OUT medianSalary DECIMAL(7,2))
LANGUAGE SQL
BEGIN
  DECLARE v_numRecords INTEGER DEFAULT 1;
  DECLARE v_counter INTEGER DEFAULT 0;
  DECLARE c1 CURSOR FOR
    SELECT salary
    FROM staff
    WHERE dept = deptNumber
    ORDER BY salary;
  DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;
  SET medianSalary = 0;
  SELECT COUNT(*) INTO v_numRecords
    FROM staff
    WHERE dept = deptNumber;
  OPEN c1;
  WHILE v_counter < (v_numRecords/2 + 1) DO
    FETCH c1 INTO medianSalary;
    SET v_counter = v_counter +1;
  END WHILE;
  CLOSE c1;
END
```

Appendix A. SQL limits

The following tables describe certain SQL and database limits imposed by the Db2 for i database manager.

Note:

- System storage limits may preclude the limits specified here. For example, see “[Maximum row sizes](#)” on page 991.
- A limit of *storage* means that the limit is dependent on the amount of storage available.
- A limit of *statement* means that the limit is dependent on the limit for the maximum length of a statement.

Table 131. Identifier Length Limits

Identifier Limits	Db2 for i Limit
Longest authorization name	10^{135}
Longest correlation name	128
Longest cursor name	128
Longest descriptor name	128
Longest external program name (string form)	279 ¹³⁶
Longest external program name (unqualified form)	10
Longest host identifier ¹³⁷	128
Longest package version-id	64
Longest partition name	10
Longest savepoint name	128
Longest schema name	128
Longest server name	18
Longest statement name	128
Longest SQL condition name	128
Longest SQL label	128
Longest unqualified alias name	128
Longest unqualified column name	128
Longest unqualified constraint name	128
Longest unqualified distinct type name	128
Longest unqualified function name	128
Longest unqualified global variable name	128
Longest unqualified index name	128
Longest unqualified mask name	128
Longest unqualified nodegroup name	10
Longest unqualified package name	10

Table 131. Identifier Length Limits (continued)

Identifier Limits	Db2 for i Limit
Longest unqualified permission name	128
Longest unqualified procedure name	128
Longest unqualified sequence name	128
Longest unqualified specific name	128
Longest unqualified SQL parameter name	128
Longest unqualified SQL variable name	128
Longest unqualified system column name	10
Longest unqualified system object name	10
Longest unqualified system schema name	10
Longest unqualified table and view name	128
Longest unqualified trigger name	128
Longest unqualified XSR object name	128
Longest XML element name, attribute name, prefix name, or processing instruction name specified in XMLELEMENT, XMLFOREST, XMLATTRIBUTES, XMLNAMESPACES or XMLPI	128
Longest XML path name specified in XMLTABLE	128
Longest XML element name, attribute name, prefix name, or processing instruction name for a parsed XML document	1000
Longest XML schema location uniform resource identifier (URI)	1000
Longest JSON path name	128

Table 132. Numeric Limits

Numeric Limits	Db2 for i Limit
Smallest SMALLINT value	-32 768
Largest SMALLINT value	+32 767
Smallest INTEGER value	-2 147 483 648
Largest INTEGER value	+2 147 483 647
Smallest BIGINT value	-9 223 372 036 854 775 808
Largest BIGINT value	+9 223 372 036 854 775 807
Largest decimal precision	63

¹³⁵ As an application requester, Db2 for i can send an authorization name of up to 255 bytes.

¹³⁶ For REXX procedures, the limit is 33.

¹³⁷ For an RPG, COBOL, or REXX program, the limit is 64.

Table 132. Numeric Limits (continued)

Table 133. String Limits

String Limits	Db2 for i Limit
Maximum length of CHAR (in bytes)	32765 ¹⁴⁰
Maximum length of VARCHAR (in bytes)	32739 ¹⁴⁰
Maximum length of CLOB (in bytes)	2 147 483 647

138 The values shown are approximate.

¹³⁹ These are the limits for normal numbers in DECFLOAT. DECFLOAT also contains special values such as NaN and Infinity that are also valid. DECFLOAT also supports subnormal numbers that are outside of the documented range.

Table 133. String Limits (continued)

String Limits	Db2 for i Limit
Maximum length of GRAPHIC (in double-byte characters)	16382 ¹⁴⁰
Maximum length of VARGRAPHIC (in double-byte characters)	16369 ¹⁴⁰
Maximum length of DBCLOB (in double-byte characters)	1 073 741 823
Maximum length of BINARY (in bytes)	32765 ¹⁴⁰
Maximum length of VARBINARY (in bytes)	32739 ¹⁴⁰
Maximum length of BLOB (in bytes)	2 147 483 647
Maximum length of serialized XML (in bytes)	2 147 483 647
Maximum length of character constant	32740
Maximum length of a graphic constant	16370
Maximum length of binary constant	32740
Maximum length of concatenated character string	2 147 483 647
Maximum length of concatenated graphic string	1 073 741 823
Maximum length of concatenated binary string	2 147 483 647
Maximum number of hexadecimal constant digits	32 762
Maximum length of catalog comments	2000 ¹⁴¹
Maximum length of column label (in bytes)	60
Maximum length of SQL routine label	128
Maximum length of table, package, or alias label	50
Maximum length of C NUL-terminated	32739 ¹⁴⁰
Maximum length of C NUL-terminated graphic	16369 ¹⁴⁰

Table 134. XML Limits

XML Limits	Db2 for i Limit
Maximum length of an XML schema document (in bytes)	2 147 483 647
Maximum length of a parsed XML entity	1 gigabyte
Maximum depth of an internal XML tree	128

Table 135. JSON Limits

JSON Limits	Db2 for i Limit
Maximum length of an JSON document (in bytes)	2 147 483 647

¹⁴⁰ If the column is NOT NULL, the maximum is one more.

¹⁴¹ For sequences the limit is 500.

Table 136. Datetime Limits

Datetime Limits	Db2 for i Limit
Smallest DATE value	0001-01-01
Largest DATE value	9999-12-31
Smallest TIME value	00:00:00
Largest TIME value	24:00:00
Smallest TIMESTAMP value	0001-01-01-00.00.00.000000000000
Largest TIMESTAMP value	9999-12-31-24.00.00.000000000000
Smallest timestamp precision	0
Largest timestamp precision	12

Table 137. DataLink Limits

Datalink Limits	Db2 for i Limit
Maximum length of DATALINK	32718
Maximum length of DATALINK comment	254

Table 138. Database Manager Limits

Database Manager Limits	Db2 for i Limit
Relational Database	
Maximum number of schemas	storage
Maximum number of tables in a relational database	storage
Maximum number of nodes in a nodegroup	32
Schemas	
Maximum number of objects in a schema	approximately 1 000 000
Tables and Views	
Maximum number of columns in a table	8000
Maximum number of columns in a view	8000
Maximum length of a row without LOBs including all overhead	32766
Maximum length of a row with LOBs including all overhead	3 758 096 383
Maximum number of rows in a non-partitioned table	4 294 967 288
Maximum number of rows in a data partition	4 294 967 288
Maximum size of a non-partitioned table	1.7 terabytes
Maximum size of a data partition	1.7 terabytes
Maximum number of data partitions in a single partitioned table	256
Maximum number of table partitioning columns	120

Table 138. Database Manager Limits (continued)

Database Manager Limits	Db2 for i Limit
Maximum number of tables referenced in a view or materialized query table	1000 ¹⁴²
Maximum number of dependent views, materialized query tables, and indexes on a table or view.	storage
Constraints	
Maximum number of constraints on a table	5000
Maximum number of columns in a UNIQUE constraint	120
Maximum combined length of columns in a UNIQUE constraint (in bytes)	32767 ¹⁴⁰
Maximum number of referencing columns in a foreign key	120
Maximum combined length of referencing columns in a foreign key (in bytes)	32767 ¹⁴⁰
Maximum length of a CHECK constraint (in bytes)	statement
Triggers	
Maximum number of triggers on a table	300
Maximum runtime depth of cascading triggers	200
Indexes	
Maximum number of indexes on a table	approximately 15000
Maximum number of columns in an index key	120
Maximum length of an index key	32767 ¹⁴⁰
Maximum size of a non-partitioned index	1.7 terabytes
Maximum size of a partition of a partitioned index	1.7 terabytes
SQL	
Maximum length of an SQL statement (in bytes)	2 097 152
Maximum number of tables referenced in an SQL statement	1000 ¹⁴²
Maximum number of variables and constants in an SQL statement	32700 ¹⁴³
Maximum number of elements in a select list	approximately 8000 ¹⁴⁴
Maximum number of predicates in a WHERE or HAVING clause	statement
Maximum number of columns in a GROUP BY clause	total GROUP BY length
Maximum total length of columns in a GROUP BY clause	3.5 gigabytes ¹⁴⁵
Maximum number of elements in a CUBE grouping	10
Maximum number of columns in an ORDER BY clause	total ORDER BY length

Table 138. Database Manager Limits (continued)

Database Manager Limits	Db2 for i Limit
Maximum total length of columns in an ORDER BY clause	3.5 gigabytes ¹⁴⁵
Maximum levels of recursion for hierarchical query	250
Maximum levels allowed for a subquery	256
Maximum number of values for a row in an insert operation	8000
Maximum number of SET clauses in a single update operation	8000
Routines	
Maximum number of parameters in a procedure	2000 ¹⁴⁶
Maximum number of parameters in a function	2000 ¹⁴⁶
Maximum number of return columns in a table function	8000
Maximum number of nested levels for routines	storage
Types	
Maximum cardinality of an array type	2 147 483 647
Applications	
Maximum number of host variable declarations in a precompiled program	storage ¹⁴⁷
Maximum length of a host variable value (in bytes)	2 147 483 647
Maximum length of an MQ message CLOB value (in bytes)	2M
Maximum length of an MQ message varying length value (in bytes)	32000
Maximum number of declared cursors in a program	storage
Maximum number of cursors opened at one time	storage ¹⁴⁸
Maximum number of rows locked in a unit of work	500 000 000
Maximum number of DDL statements in a unit of work	131 036
Maximum number of locators in a transaction	16 000 000 ¹⁴⁹
Maximum size of an SQLDA (in bytes)	16 777 215
Maximum number of prepared statements	storage
Maximum number of savepoints active at one time	storage
Maximum number of simultaneously allocated CLI handles in a process	160 000 ¹⁵⁰
Maximum size of a package	1008 megabytes ¹⁵¹
Maximum length of a path	8843
Maximum number of schemas in a path	268
Maximum length of a password	127

Table 138. Database Manager Limits (continued)

Database Manager Limits	Db2 for i Limit
Maximum length of a hint	32
Maximum size of a program, service program, or module associated space (in bytes)	16 777 216
Maximum size of the diagnostics area	90K
Maximum size of an array variable	4GB

¹⁴² The maximum number of members (and partitions) referenced is also 1000. In DELETE and UPDATE statements the maximum number is 256. In a complex SQL statement, the number of tables that can be referenced may be limited by internal structures.

¹⁴³ The limit is restricted by internal structures and may be less depending on how the constants are used in the statement and if very large string constants or variables are used.

¹⁴⁴ The limit is based on the size of internal structures generated for the parsed SQL statement.

¹⁴⁵ The limit is 32766 if CQE processed the select statement. The limit will be less if an ICU collating sequence or ALWCPYDTA(*NO) is used.

¹⁴⁶ SQL procedures and SQL functions can have up to 2000 parameters. The number of parameters for external procedures and external functions cannot exceed 2000 and is limited by the maximum number of parameters allowed by the language.

¹⁴⁷ In RPG/400 and PL/I programs when the old parameter passing technique is used, the limit is approximately 4000. The limit is based on the number of pointers allowed in the program. In all other cases, the limit is based on operating system constraints.

¹⁴⁸ The maximum number of cursors open at one time in a single job is approximately 20 966.

¹⁴⁹ The maximum number of locators in a transaction in SQL Server mode is 209 000.

¹⁵⁰ The maximum number of allocated handles per DRDA connection is 500.

¹⁵¹ The maximum size of a DRDA package can be increased from 500 megabytes to 1 gigabyte by using a QAQQINI option.

Appendix B. Characteristics of SQL statements

This appendix contains information on the characteristics of SQL statements pertaining to the various places where they are used.

- “Actions allowed on SQL statements” on page 1421 shows whether an SQL statement can be executed, prepared interactively or dynamically, and whether the statement is processed by the requester, the server or the precompiler.
- “SQL statement data access classification for routines” on page 1424 shows the level of SQL data access that must be specified to use the SQL statement in a routine.
- “Considerations for using distributed relational database” on page 1427 provides information about the use of SQL statements when the application server is not the same as the application requester.

Actions allowed on SQL statements

Indicates whether an SQL statement can be executed, prepared interactively or dynamically, and whether the statement is processed by the requester, the server, or the precompiler.

The table below shows whether a specific Db2 statement can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler. The letter Y means yes.

Table 139. Actions allowed on SQL statements

SQL statement	Executable	Interactively or dynamically	Requesting system	Processed by	
		prepared		Server	Precompiler
ALLOCATE CURSOR ⁵	Y	Y	Y		
ALLOCATE DESCRIPTOR ^{4 5}	Y			Y	
ALTER	Y	Y			Y
ASSOCIATE LOCATORS ⁵	Y	Y	Y		
BEGIN DECLARE SECTION ^{4 5}					Y
CALL	Y	Y		Y	
CLOSE ⁴	Y				Y
COMMENT	Y	Y		Y	
COMMIT	Y	Y		Y	
compound (dynamic)	Y	Y		Y	
CONNECT (type 1 and type 2) ^{4 5}	Y		Y		
CREATE	Y	Y		Y	
DEALLOCATE DESCRIPTOR ^{4 5}	Y			Y	
DECLARE CURSOR ⁴					Y
DECLARE GLOBAL TEMPORARY TABLE		Y	Y		
DECLARE PROCEDURE ^{4 5}					Y
DECLARE STATEMENT ^{4 5}					Y

Table 139. Actions allowed on SQL statements (continued)

SQL statement	Executable	Interactively	Processed by	
		or dynamically prepared	Requesting system	Server
DECLARE VARIABLE ^{4 5}				Y
DELETE	Y	Y		Y

TRANSFER OWNERSHIP	Y	Y		Y
TRUNCATE	Y	Y		Y
UPDATE	Y	Y		Y
VALUES ¹	Y			Y
VALUES INTO ⁵	Y	Y		Y
WHENEVER ^{4 5}				Y

Table 139. Actions allowed on SQL statements (continued)

SQL statement	Interactively		Processed by	
	Executable	or dynamically prepared	Requesting system	Server

Notes:

1. This statement can only be used in the triggered action of a trigger.
2. This statement can only be used in an SQL function, SQL procedure, or SQL trigger.
3. This statement can only be used in a procedure.
4. This statement is not applicable in a Java program.
5. This statement is not supported in a REXX program.
6. The target of the SET variable statement must be a global variable.

SQL statement data access classification for routines

Indicates the level of SQL data access that must be specified to use the SQL statement in a routine.

The following table indicates whether an SQL statement (specified in the first column) is allowed to execute in a function or procedure with the specified SQL data access classification. If an executable SQL statement is encountered in a function or procedure defined with NO SQL, SQLSTATE 38001 is returned. For other executions contexts, SQL statements that are not supported in any context return SQLSTATE 38003. For other SQL statements not allowed in a CONTAINS SQL context, SQLSTATE 38004 is returned and in a READS SQL DATA context, SQLSTATE 38002 is returned. During creation of an SQL function or SQL procedure, a statement that does not match the SQL data access classification will cause SQLSTATE 42895 to be returned.

Table 140. SQL Statement and SQL Data Access Classification

SQL Statement	NO SQL	CONTAINS SQL	READS SQL DATA	MODIFIES SQL DATA
ALLOCATE CURSOR			Y	Y
ALLOCATE DESCRIPTOR			Y	Y
ALTER ...				Y
ASSOCIATE LOCATORS			Y	Y
BEGIN DECLARE SECTION	Y ¹	Y	Y	Y
CALL		Y	Y	Y
CLOSE			Y	Y
COMMENT				Y
COMMIT ³		Y	Y	Y
compound (dynamic)		Y ²	Y ²	Y
CONNECT (type 1 and type 2) ³				
CREATE ...				Y
DEALLOCATE DESCRIPTOR			Y	Y
DECLARE CURSOR	Y ¹	Y	Y	Y

Table 140. SQL Statement and SQL Data Access Classification (continued)

SQL Statement	NO SQL	CONTAINS SQL	READS SQL DATA	MODIFIES SQL DATA
DECLARE GLOBAL TEMPORARY TABLE				Y
DECLARE PROCEDURE	Y ¹	Y	Y	Y
DECLARE STATEMENT	Y ¹	Y	Y	Y
DECLARE VARIABLE	Y ¹	Y	Y	Y
DELETE				Y
DESCRIBE			Y	Y
DESCRIBE CURSOR			Y	Y
DESCRIBE INPUT			Y	Y
DESCRIBE PROCEDURE			Y	Y
DESCRIBE TABLE			Y	Y
DISCONNECT ³				
DROP ...				Y
END DECLARE SECTION	Y ¹	Y	Y	Y
EXECUTE		Y ²	Y ²	Y
EXECUTE IMMEDIATE		Y ²	Y ²	Y
FETCH			Y	Y
FREE LOCATOR		Y	Y	Y
GET DESCRIPTOR			Y	Y
GET DIAGNOSTICS		Y	Y	Y
GRANT ...				Y
HOLD LOCATOR		Y	Y	Y
INCLUDE	Y ¹	Y	Y	Y
INSERT				Y
LABEL				Y
LOCK TABLE		Y	Y	Y
MERGE				Y
OPEN			Y	Y
PREPARE		Y	Y	Y
REFRESH TABLE				Y
RELEASE CONNECTION ³				
RELEASE SAVEPOINT				Y
RENAME				Y
REVOKE ...				Y

Table 140. SQL Statement and SQL Data Access Classification (continued)

SQL Statement	NO SQL	CONTAINS SQL	READS SQL DATA	MODIFIES SQL DATA
ROLLBACK ³		Y	Y	Y
ROLLBACK TO SAVEPOINT				Y
SAVEPOINT				Y
SELECT INTO			Y	Y
SET CONNECTION ³				
SET CURRENT DEBUG MODE			Y	Y
SET CURRENT DECFLOAT ROUNDING MODE		Y	Y	Y
SET CURRENT DEGREE			Y	Y
SET CURRENT IMPLICIT XMLPARSE OPTION		Y	Y	Y
SET CURRENT TEMPORAL SYSTEM_TIME		Y	Y	Y
SET DESCRIPTOR			Y	Y
SET ENCRYPTION PASSWORD		Y	Y	Y
SET OPTION	Y ¹	Y	Y	Y
SET PATH		Y	Y	Y
SET RESULT SETS		Y	Y	Y
SET SCHEMA			Y	Y
SET SESSION AUTHORIZATION			Y	Y
SET TRANSACTION		Y	Y	Y
SET variable		Y	Y	Y
SIGNAL		Y	Y	Y
TRANSFER OWNERSHIP				Y
TRUNCATE				Y
UPDATE				Y
VALUES				
VALUES INTO			Y	Y
WHENEVER	Y ¹	Y	Y	Y

Note:

1. Although the NO SQL option implies that no SQL statements can be specified, non-executable statements are not restricted.
2. It depends on the statement being executed. The statement specified for the EXECUTE statement or any statement executed within a compound (dynamic) statement must be a statement that is allowed in the context of the particular SQL access level in effect. For example, if the SQL access level in effect is READS SQL DATA, the statement must not be an INSERT, UPDATE, or DELETE.

3. Connection management and transaction statements are not allowed in a procedure running on a remote server. COMMIT and ROLLBACK are not allowed in an ATOMIC SQL procedure.

Considerations for using distributed relational database

This section contains information that may be useful in developing applications that use application servers which are not the same product as their application requesters.

All Db2 products support extensions to IBM SQL. Some of these extensions are product-specific, but many are already shared by more than one product or support is planned but not yet generally available.

For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running through the application requester of a database manager that does not support some of those statements and clauses. Restrictions to this general rule are identified by application requester:

- for Db2 for z/OS Application Server application requester, see [Table 141 on page 1427](#)
- for Db2 for i Application Server application requester, see [Table 142 on page 1428](#)
- for Db2 LUW application requester, see [Table 143 on page 1428](#).

Note that an 'R' in the table indicates that this SQL function is not supported in the specified environment. An 'R' in every column of the same row means that the function is available only if the current server and requester are the same product or that the statement is blocked by the application requester from being processed at the application server.

Table 141. Db2 for z/OS Application Requester

SQL Statement or Function	Db2 for z/OS Application Server	Db2 for i Application Server	Db2 LUW Application Server
COMMIT HOLD	R	R	R
DECLARE STATEMENT			
DECLARE TABLE			
DECLARE VARIABLE			
DESCRIBE TABLE			R
DESCRIBE with USING clause			R
DISCONNECT	R	R	R
ROWID data types			R
DATALINK data types	R	R	R
BINARY and VARBINARY data types			R
Host declarations not documented in language specific appendices		152	152
PREPARE with USING clause			R
ROLLBACK HOLD	R	R	R
SET CURRENT PACKAGESET			
SET variable		R	R
SET TRANSACTION	R	R	R
Scrollable Cursor statements	R	R	R
UPDATE cursor - FOR UPDATE clause not specified			

Table 142. Db2 for i Application Requester

SQL Statement or Function	Db2 for z/OS Application Server	Db2 for i Application Server	Db2 LUW Application Server
COMMIT HOLD	R		R
DECLARE STATEMENT			
DECLARE TABLE			
DECLARE VARIABLE			
DESCRIBE TABLE			R
DESCRIBE with USING clause			R
DISCONNECT			
Host Variables - optional colon	R	R	R
ROWID data types			R
DATALINK data types	R		R
BINARY and VARBINARY data types			R
Host declarations not documented in language specific appendices	152		152
PREPARE with USING clause			R
ROLLBACK HOLD	R		R
SET CURRENT PACKAGESET	R	R	R
SET variable	R	R	R
SET TRANSACTION	R		R
Scrollable Cursor statements	R		R
UPDATE cursor - FOR UPDATE clause not specified	R		

Table 143. Db2 LUW application requester

SQL Statement or Function	Db2 for z/OS Application Server	Db2 for i Application Server	Db2 LUW Application Server
COMMIT HOLD	R	R	R

DECLARE TABLE	R	R	R
DECLARE VARIABLE	R	R	R
DESCRIBE TABLE	R	R	R
DESCRIBE with USING clause	R	R	R
DISCONNECT			
Host Variables - optional colon	R	R	R

¹⁵² The statement is supported if the application requester understands it.

Table 143. Db2 LUW application requester (continued)

SQL Statement or Function	Db2 for z/OS Application Server	Db2 for i Application Server	Db2 LUW Application Server
ROWID data types	153	153	R
DATALINK data types	R	R	R
BINARY and VARBINARY data types	R	R	R
Host declarations not documented in language specific appendices	152	152	
PREPARE with USING clause	R	R	R
ROLLBACK HOLD	R	R	R
SET CURRENT PACKAGESET			
SET variable	R	R	R
SET TRANSACTION	R	R	R
Scrollable Cursor statements	R	R	R
UPDATE cursor - FOR UPDATE clause not specified	R		

CONNECT (type 1) and CONNECT (type 2) differences

There are two types of CONNECT statements.

They have the same syntax, but they have different semantics:

- CONNECT (type 1) is used for remote unit of work. See “[Remote unit of work](#)” on page 37.
- CONNECT (type 2) is used for distributed unit of work. See “[CONNECT \(type 2\)](#)” on page 806.

The following table summarizes the differences between CONNECT (type 1) and CONNECT (type 2) rules:

Table 144. CONNECT (type 1) and CONNECT (type 2) Differences

Type 1 Rules	Type 2 Rules
CONNECT statements can only be executed when the activation group is in the connectable state. No more than one CONNECT statement can be executed within the same unit of work.	More than one CONNECT statement can be executed within the same unit of work. There are no rules about the connectable state.

¹⁵³ The Db2 LUW application requester application requester will process a ROWID data type at the application server using the compatible VARCHAR(40) FOR BIT DATA data type.

Table 144. CONNECT (type 1) and CONNECT (type 2) Differences (continued)

Type 1 Rules	Type 2 Rules
If the CONNECT statement fails because the server name is not listed in the local directory, the connection state of the activation group is unchanged.	If a CONNECT statement fails, the current SQL connection is unchanged and any subsequent SQL statements are executed by the current server.
If a CONNECT statement fails because the activation group is not in the connectable state, the SQL connection status of the activation group is unchanged.	
If a CONNECT statement fails for any other reason, the activation group is placed in the unconnected state.	
CONNECT ends all existing connections of the activation group. Accordingly, CONNECT also closes any open cursors for that activation group.	CONNECT does not end connections and does not close cursors.
A CONNECT to the current server is executed like any other CONNECT (type 1) statement.	A CONNECT to the current server causes an error.

Determining the CONNECT rules that apply

A program preparation option is used to specify the type of CONNECT that will be performed by a program. The program preparation option is specified using the RDBCNNMTH parameter on the CRTSQLxxx command.

Connecting to servers that only support remote unit of work

CONNECT (type 2) connections to application servers that only support remote unit of work might result in connections that are read-only.

If a CONNECT (type 2) is performed to an application server that only supports remote unit of work:

- The connection allows read-only operations if, at the time of the connect, there are any dormant connections that allow updates. In this case, the connection does not allow updates.
- Otherwise, the connection allows updates.

If a CONNECT (type 2) is performed to an application server that supports distributed unit of work:

- The connection allows read-only operations when there are dormant connections that allow updates to application servers that only support remote unit of work. In this case, the connection allows updates as soon as the dormant connection is ended.
- Otherwise, the connection allows updates.

¹⁵⁴ Db2 for i using the initial DRDA support for native TCP/IP is an example of an application server that supports only remote unit of work.

Appendix C. SQLCA (SQL communication area)

An SQLCA is a set of variables that may be updated at the end of the execution of every SQL statement. A program that contains executable SQL statements may provide one, but no more than one SQLCA (unless a stand-alone SQLCODE or a stand-alone SQLSTATE variable is used instead), except in Java, where the SQLCA is not applicable.

Instead of using an SQLCA, the GET DIAGNOSTICS statement can be used in all languages to return return codes and other information about the previous SQL statement. For more information, see “[GET DIAGNOSTICS](#)” on page 1144.

The SQL INCLUDE statement can be used to provide the declaration of the SQLCA in all host languages except Java, RPG, or REXX. For information about the use of the SQLCA in a REXX procedure, see the [Embedded SQL Programming](#) topic collection. For information about how to access the information regarding errors and warnings in Java, refer to the [IBM Developer Kit for Java](#) topic collection.

In C, COBOL, and PL/I, the name of the storage area must be SQLCA. Every SQL statement must be within the scope of its declaration.

If a stand-alone SQLCODE or SQLSTATE is specified in the program, the SQLCA must not be included. For more information, see “[SQL diagnostic information](#)” on page 664.

The stand-alone SQLCODE and stand-alone SQLSTATE must not be specified in the Java or REXX language.

Field descriptions

The names in the following table are those provided by the SQL INCLUDE statement.

For the most part, C (and C++), COBOL, and PL/I use the same names. RPG names are different, because in RPG/400, they are limited to 6 characters. In ILE RPG, both a long name and the short 6 character name is supported. Note one instance where PL/I names differ from the COBOL names.

Table 145. Names Provided by the SQL INCLUDE Statement

C Name COBOL Name PL/I Name	ILE RPG Name RPG/400 Name	Field Data Type	Field Value
SQLCAID sqlcaid	SQLCAID SQLAID	CHAR(8)	An "eye catcher" for storage dumps, containing 'SQLCA'.
SQLCABC sqlcbc	SQLCABC SQLABC	INTEGER	Contains the length of the SQLCA, 136.
SQLCODE sqlcode	SQLCODE SQLCOD	INTEGER	Contains an SQL return code. Code Meaning 0 Successful execution although SQLWARN indicators might have been set. positive Successful execution, but with a warning condition. negative Error condition.

Table 145. Names Provided by the SQL INCLUDE Statement (continued)

C Name COBOL Name PL/I Name	ILE RPG Name RPG/400 Name	Field Data Type	Field Value
SQLERRML ¹ sqlerrml	SQLERRML SQLERL	SMALLINT	Length indicator for SQLERRMC, in the range 0 through 70. 0 means that the value of SQLERRMC is not pertinent.
SQLERRMC ¹ sqlerrmc	SQLERRMC SQLERM	CHAR(70)	Contains message replacement text associated with the SQLCODE. For CONNECT and SET CONNECTION, the SQLERRMC field contains information about the connection, see Table 148 on page 1436 for a description of the replacement text.
SQLERRP sqlerrp	SQLERRP SQLERP	CHAR(8)	<p>Contains the name of the product and module returning the error or warning. The first three characters identify the product:</p> <ul style="list-style-type: none"> • ARI for Db2 for VM and VSE • DSN for Db2 for z/OS • QSQ for Db2 for i • SQL for all other Db2 products <p>See “CONNECT (type 1)” on page 801 or “CONNECT (type 2)” on page 806 for additional information.</p>
SQLERRD sqlerrd	SQLERRD SQLERR ²	Array	Contains six INTEGER variables that provide diagnostic information, see Table 147 on page 1434 for a description of the diagnostic information.
SQLWARN sqlwarn	SQLWARN SQLWRN ³	CHAR(11)	A set of 11 CHAR(1) warning indicators, each containing blank or 'W' or 'N'.
SQLSTATE sqlstate	SQLSTATE SQLSTT	CHAR(5)	A return code that indicates the outcome of the most recently executed SQL statement.

Notes:

1

In COBOL, SQLERRM includes SQLERRML and SQLERRMC. In PL/I, the varying-length string SQLERRM is equivalent to SQLERRML prefixed to SQLERRMC.

2

In RPG/400, SQLERR is defined as 24 characters (not an array) that are redefined by the fields SQLER1 through SQLER6. The fields are full-word binary. In ILE RPG, SQLERR is also redefined as an array. The name of the array is SQLERRD.

3

In RPG/400, SQLWRN is defined as 11 characters (not an array) that are redefined by the fields SQLWNO through SQLWNA. The fields are full-word binary. In ILE RPG, SQLWRN is also redefined as an array. The name of the array is SQLWARN.

Table 146. SQLWARN Diagnostic Information

C Name COBOL Name PL/I Name	ILE RPG Name RPG/400 Name	Field Value
SQLWARN0 sqlwarn[0]	SQLWARN(1) SQLWN0	Contains 'W' if at least one other indicator contains 'W' or 'N'; it is blank if all other indicators are blank.
SQLWARN1 sqlwarn[1]	SQLWARN(2) SQLWN1	Contains 'W' if the value of a string column was truncated when assigned to a host variable. Contains 'N' if *NOCNULRQD was specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) and if the value of a string column was assigned to a C NUL-terminated host variable and if the host variable was large enough to contain the result but not large enough to contain the NUL-terminator.
SQLWARN2 sqlwarn[2]	SQLWARN(3) SQLWN2	Contains 'W' if the null values were eliminated from the argument of a function; not necessarily set to 'W' for the MIN or MAX function because its results are not dependent on the elimination of null values.
SQLWARN3 sqlwarn[3]	SQLWARN(4) SQLWN3	Contains 'W' if the number of columns is larger than the number of host variables.
SQLWARN4 sqlwarn[4]	SQLWARN(5) SQLWN4	Contains 'W' if a prepared UPDATE or DELETE statement does not include a WHERE clause.
SQLWARN5 sqlwarn[5]	SQLWARN(6) SQLWN5	Contains a character value of 1 (read only), 2 (read and delete), or 4 (read, delete, and update) to reflect capability of a cursor after the OPEN statement.
SQLWARN6 sqlwarn[6]	SQLWARN(7) SQLWN6	Contains 'W' if date arithmetic results in an end-of-month adjustment.
SQLWARN7 sqlwarn[7]	SQLWARN(8) SQLWN7	Reserved
SQLWARN8 sqlwarn[8]	SQLWARN(9) SQLWN8	Contains 'W' if the result of a character conversion contains the substitution character.
SQLWARN9 sqlwarn[9]	SQLWARN(10) SQLWN9	Reserved
SQLWARNA sqlwarn[10]	SQLWARN(11) SQLWNA	Reserved

Table 147. SQLERRD Diagnostic Information

C Name COBOL Name PL/I Name	ILE RPG Name RPG/400 Name	Field Value
SQLERRD(1) sqlerrd[0]	SQLERRD(1) SQLER1	<p>Contains the last four characters of the CPF escape message if SQLCODE is less than 0. For example, if the message is CPF5715, X'F5F7F1F5' is placed in SQLERRD(1).¹</p> <p>For a call to a procedure, contains the return status value specified on the RETURN statement. If a return status value is not specified on the RETURN statement or the procedure is an external procedure,</p> <ul style="list-style-type: none"> • 0 is returned if the CALL statement is successful, or • –1 is returned if the CALL statement is not successful.
SQLERRD(2) sqlerrd[1]	SQLERRD(2) SQLER2	<p>Contains the last four characters of a CPD diagnostic message if the SQL code is less than 0.¹</p> <p>For a CALL statement, SQLERRD(2) contains the number of result sets.</p> <p>For an OPEN statement, SQLERRD(2) contains an estimated number of rows in the result set.</p>
SQLERRD(3) sqlerrd[2]	SQLERRD(3) SQLER3	<p>For a CONNECT for status statement, SQLERRD(3) contains information about the connection status. See “CONNECT (type 2)” on page 806 for more information.</p> <p>For INSERT, MERGE, UPDATE, REFRESH, and DELETE, shows the number of rows affected.</p> <p>For a TRUNCATE statement, the value will be -1.</p> <p>For a FETCH statement, SQLERRD(3) contains the number of rows fetched.</p> <p>For the PREPARE statement, contains the estimated number of rows selected. If the number of rows is greater than 2 147 483 647, then 2 147 483 647 is returned.</p>

Table 147. SQLERRD Diagnostic Information (continued)

C Name COBOL Name PL/I Name	ILE RPG Name RPG/400 Name	Field Value
SQLERRD(4) sqlerrd[3]	SQLERRD(4) SQLER4	<p>For the PREPARE statement, contains a relative number estimate of the resources required for every execution. This number varies depending on the current availability of indexes, file sizes, CPU model, etc. It is an estimated cost for the access plan chosen by the Db2 for i Query Optimizer.</p> <p>For a CONNECT and SET CONNECTION statement, SQLERRD(4) contains the type of conversation used and whether or not committable updates can be performed. See “CONNECT (type 2)” on page 806 for more information.</p> <p>For a CALL statement, SQLERRD(4) contains the message key of the error that caused the procedure to fail. The QMHRTVPM API can be used to return the message description for the message key.</p> <p>For a trigger error in a DELETE, INSERT MERGE, or UPDATE statement, SQLERRD(4) contains the message key of the error that was signaled from the trigger program. The QMHRTVPM API can be used to return the message description for the message key.</p> <p>For a FETCH statement, if the result row does not contain a LOB, SQLERRD(4) contains the length of the row(s) retrieved.</p> <p>For an OPEN statement, if the result row does not contain a LOB, SQLERRD(4) contains the length of a result row.</p>
SQLERRD(5) sqlerrd[4]	SQLERRD(5) SQLER5	<p>For a CONNECT or SET CONNECTION statement, SQLERRD(5) contains:</p> <ul style="list-style-type: none"> • -1 if the connection is unconnected • 0 if the connection is local • 1 if the connection is remote <p>For a DELETE, INSERT, MERGE, or UPDATE statement, shows the number of rows affected by referential constraints and triggers.</p> <p>For an EXECUTE IMMEDIATE or PREPARE statement, may contain the position of a syntax error.</p> <p>For a multiple-row FETCH statement, SQLERRD(5) contains +100 if the last row currently in the table has been fetched.</p> <p>For a PREPARE statement, SQLERRD(5) contains the number of parameter markers in the prepared statement.</p>
SQLERRD(6) sqlerrd[5]	SQLERRD(6) SQLER6	<p>Contains the SQL completion message identifier when the SQLCODE is 0.</p> <p>In all other cases, it is undefined.</p>

Note:

¹

SQLERRD(1) and SQLERRD(2) are set only if appropriate and only if the current server is Db2 for i.

Table 148. SQLERRMC Replacement Text for CONNECT and SET CONNECTION

Description	Data type
Relational Database Name	CHAR(18)
Product Identification (same as SQLERRP)	CHAR(8)
User ID of the server job	CHAR(10)
Connection method (*DUW or *RUW)	CHAR(10)
DDM server class name	CHAR(10)
QAS Db2 for i	
QDB2 Db2 for z/OS	
QDB2/6000 Db2 for AIX	
QDB2/HPUX Db2 for HP-UX**	
QDB2/LINUX Db2 for Linux®	
QDB2/NT Db2 for Windows** NT, 2000, and XP	
QDB2/SUN Db2 for SUN** Solaris**	
QSQLDS/VM Db2 Server for VM	
QSQLDS/VSE Db2 Server for VSE	
Connection type (same as SQLERRD(4))	SMALLINT

INCLUDE SQLCA declarations

This section shows the equivalent INCLUDE SQLCA declaration for C and C++, COBOL, PL/I, RPG/400, and ILE RPG.

In **C and C++**, INCLUDE SQLCA declarations are equivalent to the following:

```
#ifndef SQLCODE
struct sqlca
{
    unsigned char sqlcaid[8];
    long sqlcabc;
    long sqlcode;
    short sqlerrml;
    unsigned char sqlerrmc[70];
    unsigned char sqlerrrp[8];
    long sqlerrrd[6];
    unsigned char sqlwarn[11];
    unsigned char sqlstate[5];
};
#define SQLCODE sqlca.sqlcode
#define SQLWARN0 sqlca.sqlwarn[0]
#define SQLWARN1 sqlca.sqlwarn[1]
#define SQLWARN2 sqlca.sqlwarn[2]
#define SQLWARN3 sqlca.sqlwarn[3]
#define SQLWARN4 sqlca.sqlwarn[4]
#define SQLWARN5 sqlca.sqlwarn[5]
#define SQLWARN6 sqlca.sqlwarn[6]
#define SQLWARN7 sqlca.sqlwarn[7]
#define SQLWARN8 sqlca.sqlwarn[8]
```

```

#define      SQLWARN9  sqlca.sqlwarn[9]
#define      SQLWARNA sqlca.sqlwarn[10]
#define      SQLSTATE   sqlca.sqlstate
#endif
struct sqlca sqlca;

```

In **COBOL**, INCLUDE SQLCA declarations are equivalent to the following:

```

01 SQLCA.
 05 SQLCAID      PIC X(8).
 05 SQLCABC      PIC S9(9) BINARY.
 05 SQLCODE      PIC S9(9) BINARY.
 05 SQLERRM.
    49 SQLERRML  PIC S9(4) BINARY.
    49 SQLERRMC  PIC X(70).
 05 SQLERRP      PIC X(8).
 05 SQLERRD      OCCURS 6 TIMES
                  PIC S9(9) BINARY.
 05 SQLWARN.
    10 SQLWARN0   PIC X(1).
    10 SQLWARN1   PIC X(1).
    10 SQLWARN2   PIC X(1).
    10 SQLWARN3   PIC X(1).
    10 SQLWARN4   PIC X(1).
    10 SQLWARN5   PIC X(1).
    10 SQLWARN6   PIC X(1).
    10 SQLWARN7   PIC X(1).
    10 SQLWARN8   PIC X(1).
    10 SQLWARN9   PIC X(1).
    10 SQLWARNA   PIC X(1).
 05 SQLSTATE     PIC X(5).

```

Note: In COBOL, INCLUDE SQLCA must not be specified outside the Working Storage Section.

In **PL/I**; INCLUDE SQLCA declarations are equivalent to the following:

```

DCL 1 SQLCA,
 2 SQLCAID      CHAR(8),
 2 SQLCABC      BIN FIXED(31),
 2 SQLCODE      BIN FIXED(31),
 2 SQLERRM      CHAR(70) VAR,
 2 SQLERRP      CHAR(8),
 2 SQLERRD(6)   BIN FIXED(31),
 2 SQLWARN,
  3 SQLWARN0   CHAR(1),
  3 SQLWARN1   CHAR(1),
  3 SQLWARN2   CHAR(1),
  3 SQLWARN3   CHAR(1),
  3 SQLWARN4   CHAR(1),
  3 SQLWARN5   CHAR(1),
  3 SQLWARN6   CHAR(1),
  3 SQLWARN7   CHAR(1),
  3 SQLWARN8   CHAR(1),
  3 SQLWARN9   CHAR(1),
  3 SQLWARNA   CHAR(1),
 2 SQLSTATE     CHAR(5);

```

In **RPG/400**; SQLCA declarations are equivalent to the following:

I	SQLCA	DS	
I		1 8 SQLAID	SQL
I		B 9 120SQLABC	SQL
I		B 13 160SQLCOD	SQL
I		B 17 180SQLERL	SQL
I		19 88 SQLERM	SQL
I		89 96 SQLERP	SQL
I		97 120 SQLERR	SQL
I		B 97 1000SQLER1	SQL
I		B 101 1040SQLER2	SQL
I		B 105 1080SQLER3	SQL
I		B 109 1120SQLER4	SQL
I		B 113 1160SQLER5	SQL

I	B	117	1200SQLER6	SQL
I		121	131 SQLWRN	SQL
I		121	121 SQLWN0	SQL
I		122	122 SQLWN1	SQL
I		123	123 SQLWN2	SQL
I		124	124 SQLWN3	SQL
I		125	125 SQLWN4	SQL
I		126	126 SQLWN5	SQL
I		127	127 SQLWN6	SQL
I		128	128 SQLWN7	SQL
I		129	129 SQLWN8	SQL
I		130	130 SQLWN9	SQL
I		131	131 SQLWNA	SQL
I		132	136 SQLSTT	SQL

In **ILE RPG**; SQLCA declarations are equivalent to the following:

```
// SQL COMMUNICATION AREA
DCL-DS SQLCA;
  SQLCAID CHAR(8) INZ(X'0000000000000000');
  SQLAID CHAR(8) OVERLAY(SQLCAID);
  SQLCABC INT(10);
  SQLABC BINDEC(9) OVERLAY(SQLCABC);
  SQLCODE INT(10);
  SQLCOD BINDEC(9) OVERLAY(SQLCODE);
  SQLERRML INT(5);
  SQLERL BINDEC(4) OVERLAY(SQLERRML);
  SQLERRMC CHAR(70);
  SQLERM CHAR(70) OVERLAY(SQLERRMC);
  SQLERRP CHAR(8);
  SQLERP CHAR(8) OVERLAY(SQLERRP);
  SQLERR CHAR(24);
  SQLER1 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER2 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER3 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER4 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER5 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER6 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLERRD INT(10) DIM(6) OVERLAY(SQLERR);
  SQLWRN CHAR(11);
  SQLWN0 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN1 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN2 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN3 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN4 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN5 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN6 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN7 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN8 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN9 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWNA CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWARN CHAR(1) DIM(11) OVERLAY(SQLWRN);
  SQLSTATE CHAR(5);
  SQLSTT CHAR(5) OVERLAY(SQLSTATE);
END-DS SQLCA;
```

Appendix D. SQLDA (SQL descriptor area)

An SQLDA is a set of variables that is used for execution of the SQL DESCRIBE statement, and it may optionally be used by the PREPARE, OPEN, CALL, FETCH, and EXECUTE statements.

An SQLDA can be used in a DESCRIBE or PREPARE statement, altered with the addresses of storage areas¹⁵⁵, and then used again in a FETCH statement.

SQLDAs are supported for all languages, but predefined declarations are provided only for C (and C++), COBOL, ILE RPG, PL/I, and REXX. In REXX, the SQLDA is somewhat different than in the other languages; for information about the use of SQLDAs in REXX, see the [Embedded SQL Programming](#) topic collection.

The meaning of the information in an SQLDA depends on its use.

- When an SQLDA is used in a DESCRIBE or PREPARE statement, an SQLDA provides information to an application program about a prepared *select-statement*. Each column of the result table is described in an SQLVAR occurrence or set of related SQLVAR occurrences.
- In OPEN, EXECUTE, CALL, and FETCH, an SQLDA provides information to the database manager about storage areas for input or output data. Each storage area is described in the SQLVARs.
 - For OPEN and EXECUTE of a statement other than CALL, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an input value which is substituted for a parameter marker in the associated SQL statement that was previously prepared.
 - For FETCH, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an output value from a row of the result table.
 - For CALL and EXECUTE of a prepared CALL statement, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an input or output value (or both) that corresponds to an argument in the argument list for the procedure.

An SQLDA consists of four variables in a header followed by an arbitrary number of occurrences of a *base SQLVAR*. When the SQLDA describes either LOBs or distinct types the base SQLVARs are followed by the same number of occurrences of an *extended SQLVAR*.

Base SQLVAR entry

The base SQLVAR entry is always present. The fields of this entry contain the base information about the column or variable such as data type code, length attribute (except for LOBs), column name (or label), CCSID, variable address, and indicator variable address.

Extended SQLVAR entry

The extended SQLVAR entry is needed (for each column) if the result includes any LOB or distinct type columns. For distinct types, the extended SQLVAR contains the distinct type name. For LOBs, the extended SQLVAR contains the length attribute of the variable and a pointer to the buffer that contains the actual length. If locators or file reference variables are used to represent LOBs, an extended SQLVAR is not necessary.

The extended SQLVAR entry is also needed for each column when:

- USING BOTH is specified, which indicates that column names and labels are returned.
- USING ALL is specified, which indicates that column names, labels, and system column names are returned.

The fields in the extended SQLVAR that return LOB and distinct type information do not overlap, and the fields that return LOB and label information do not overlap. Depending on the combination of labels, LOBs and distinct types, more than one extended SQLVAR entry per column may be required to return the information. See “[Determining how many SQLVAR occurrences are needed](#)” on page 1441.

¹⁵⁵ A storage area could be the storage for a variable defined in the program (that may also be a host variable) or an area of storage explicitly allocated by the application.

Field descriptions in an SQLDA header

An SQLDA consists of four variables in a header structure followed by an arbitrary number of occurrences of a sequence of five variables collectively named SQLVAR. In OPEN, CALL, FETCH, and EXECUTE, each occurrence of SQLVAR describes a variable. In PREPARE and DESCRIBE, each occurrence describes a column of a result table.

The SQL INCLUDE statement provides the following field names:

Table 149. Field Descriptions for an SQLDA Header

C Name ¹⁵⁶ PL/I Name COBOL Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager except for SQLN)	Usage in FETCH, OPEN, CALL, or EXECUTE (set by the user prior to executing the statement)
sqlaid SQLDAID	CHAR(8)	<p>An 'eye catcher' for storage dumps, containing 'SQLDA'.</p> <p>The 7th byte of the SQLDAID can be used to determine whether more than one SQLVAR entry is needed for each column. For details, see "Determining how many SQLVAR occurrences are needed" on page 1441.</p>	<p>A '2' in the 7th byte indicates that two SQLVAR entries were allocated for each column.</p> <p>A '3' in the 7th byte indicates that three SQLVAR entries were allocated for each column.</p> <p>A '4' in the 7th byte indicates that four SQLVAR entries were allocated for each column.</p>
sqldabc SQLDABC	INTEGER	Length of the SQLDA.	<p>Number of bytes of storage allocated for the SQLDA. Enough storage must be allocated to contain SQLN occurrences. SQLDABC must be set to a value greater than or equal to $16+SQLN*(80)$, where 80 is the length of an SQLVAR occurrence. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker.</p>
sqln SQLN	SMALLINT	<p>Unchanged by the database manager. Must be set to a value greater than or equal to zero before the PREPARE or DESCRIBE statement is executed. It should be set to a value that is greater than or equal to the number of columns in the result or a multiple of the number of columns in the result when multiple sets of SQLVAR entries are necessary. Indicates the total number of occurrences of SQLVAR.</p>	<p>Total number of occurrences of SQLVAR provided in the SQLDA. SQLN must be set to a value greater than or equal to zero.</p> <p>If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.</p>

¹⁵⁶ In this column, the lowercase name is the C Name. The uppercase name is the COBOL, PL/I, or RPG Name.

Table 149. Field Descriptions for an SQLDA Header (continued)

C Name ¹⁵⁶ PL/I Name COBOL Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager except for SQLN)	Usage in FETCH, OPEN, CALL, or EXECUTE (set by the user prior to executing the statement)
sqld SQLD	SMALLINT	The number of columns described by occurrences of SQLVAR (zero if the statement being described is not a select-statement, CALL, or VALUES INTO).	Number of occurrences of SQLVAR entries in the SQLDA that are used when executing the statement. SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

Determining how many SQLVAR occurrences are needed

The number of SQLVAR occurrences needed depends on the statement that the SQLDA was provided for and the data types of the columns or parameters being described. See the tables above for more information.

The 7th byte of SQLDAID is always set to the number of sets of SQLVARs necessary when LOBs or UDTs are in the result set.

If SQLD is not set to a sufficient number of SQLVAR occurrences:

- When LOBs and UDTs are not in the result set, SQLD is set to the total number of SQLVAR occurrences needed for all sets. When there are LOBs or UDTs in the result set, SQLD is set to the number of columns in the result table and the seventh byte of SQLDAID indicates the number of sets of SQLVAR entries needed. The number of required SQLVAR entries can always be determined by multiplying SQLD by the value in the seventh byte of SQLDAID.
- A warning (SQLSTATE 01594) is returned if at least enough SQLVARs were specified for the Base SQLVAR Entries. The Base SQLVAR entries are returned, but no extended SQLVARs are returned.
- A warning (SQLSTATE 01005) is returned if enough SQLVARs were not specified for even the Base SQLVAR Entries. No SQLVAR entries are returned.¹⁵⁷

Table 150 on page 1441, Table 151 on page 1442, and Table 152 on page 1442 show how to map the base and extended SQLVAR entries. For an SQLDA that contains both base and extended SQLVAR entries, the base SQLVAR entries are in the first block, followed by a block of extended SQLVAR entries, which if necessary, are followed by a second or third block of extended SQLVAR entries. In each block, the number of occurrences of the SQLVAR entry is equal to the value in SQLD even though many of the extended SQLVAR entries might be unused.

Table 150. Contents of SQLVAR Arrays for USING NAMES, USING SYSTEM NAMES, USING LABELS or USING ANY

LOBs	DISTINCT types	7th byte of SQLDAID	SQLN Minimum	First Set (Base)	Second Set (Extended)	Third Set (Extended)	Fourth Set (Extended)
No	No	Blank	n	Column names, system column names, or labels	Not used	Not used	Not used

¹⁵⁷ If LOBs or UDTs are not in the result set, the warning is only returned if the standards option is specified. For information about the standards option, see “Standards compliance” on page xix.

Table 150. Contents of SQLVAR Arrays for USING NAMES, USING SYSTEM NAMES, USING LABELS or USING ANY (continued)

LOBs	DISTINCT types	7th byte of SQLDAID	SQLN Minimum	First Set (Base)	Second Set (Extended)	Third Set (Extended)	Fourth Set (Extended)
Yes	No	2	2n	Column names, system column names, or labels	LOBs	Not used	Not used
No	Yes	2	2n	Column names, system column names, or labels	Distinct types	Not used	Not used
Yes	Yes	2	2n	Column names, system column names, or labels	LOBs and distinct types	Not used	Not used

Table 151. Contents of SQLVAR Arrays for USING BOTH

LOBs	DISTINCT types	7th byte of SQLDAID	SQLN Minimum	First Set (Base)	Second Set (Extended)	Third Set (Extended)	Fourth Set (Extended)
No	No	2	2n	Column names	Labels	Not used	Not used
Yes	No	2	2n	Column names	LOBs and labels	Not used	Not used
No	Yes	3	3n	Column names	Distinct types	Labels	Not used
Yes	Yes	3	3n	Column names	LOBs and distinct types	Labels	Not used

Table 152. Contents of SQLVAR Arrays for USING ALL

LOBs	DISTINCT types	7th byte of SQLDAID	SQLN Minimum	First Set (Base)	Second Set (Extended)	Third Set (Extended)	Fourth Set (Extended)
No	No	3	3n	System column names	Labels	Column names	Not used
Yes	No	3	3n	System column names	LOBs and labels	Column names	Not used
No	Yes	4	4n	System column names	Distinct types	Labels	Column names

Table 152. Contents of SQLVAR Arrays for USING ALL (continued)

Field descriptions in an occurrence of SQLVAR

This section includes field descriptions in an occurrence of a base and secondary SQLVAR.

Fields in an occurrence of a base SQLVAR

Table 153. Field Descriptions for an SQLVAR

C Name ¹⁵⁸	COBOL Name	PL/I Name	RPG Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager)	Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)
sqltype SQLTYPE				SMALLINT	<p>Indicates the data type of the column and whether it can contain nulls. For a description of the type codes, see Table 155 on page 1446.</p> <p>For a distinct type, the data type on which the distinct type is based is placed in this field. The base SQLVAR contains no indication that this is part of the description of a distinct type.</p>	<p>Indicates the data type of the host variable and whether an indicator variable is provided. For a description of the type codes, see Table 155 on page 1446.</p>
sqllen SQLLEN				SMALLINT	<p>The length attribute of the column. For datetime columns, the length of the string representation of the values. See Table 155 on page 1446.</p> <p>For a LOB, the value is 0 regardless of the length attribute of the LOB. Field SQLLONGLEN in the extended SQLVAR entry contains the length attribute of the LOB.</p> <p>For XML, the value is 0. Field SQLLONGLEN in the extended SQLVAR entry contains the length attribute of the LOB or XML.</p>	<p>The length attribute of the host variable. See Table 155 on page 1446.</p> <p>For a LOB, the value is 0 regardless of the length attribute of the LOB. Field SQLLONGLEN in the extended SQLVAR entry contains the length attribute of the LOB.</p> <p>For XML AS BLOB, CLOB, or DBCLOB, the value is 0.</p>
sqlres SQLRES				CHAR(12)	Reserved. Provides boundary alignment for SQLDATA.	Reserved. Provides boundary alignment for SQLDATA.

¹⁵⁸ In this column, the lowercase name is the C Name. The uppercase name is the PL/I, COBOL, and RPG Name.

Table 153. Field Descriptions for an SQLVAR (continued)

C Name ¹⁵⁸	COBOL Name	PL/I Name	RPG Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager)	Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)
sqldata SQLDATA				pointer	The CCSID of a string column or XML column as described in Table 156 on page 1449 .	<p>Contains the address of the host variable.</p> <p>For LOB host variables, if the SQLDATALEN field in the extended SQLVAR is null, this points to the four-byte LOB length, followed immediately by the LOB data.</p> <p>If the SQLDATALEN field in the extended SQLVAR is not null, this points to the LOB data and the SQLDATALEN field points to the four-byte LOB length.</p>
sqlind SQLIND				pointer	<p>For a select-statement, indicates whether the column was added as a result of using the WITH ROW CHANGE COLUMNS attribute:</p> <ul style="list-style-type: none"> • -1 ROW CHANGE TOKEN (distinct) • -2 ROW CHANGE TOKEN (not distinct) • -3 RID • -4 RID_BIT <p>Otherwise, reserved.</p>	<p>Contains the address of the indicator variable. Not used if there is no indicator variable (as indicated by an even value of SQLTYPE).</p>
sqlname SQLNAME				VARCHAR(30)	<p>The unqualified name of the column. If the column does not have a name, a string is constructed from the expression and returned.</p> <p>The name is case sensitive and does not contain surrounding delimiters.</p>	<p>Contains the CCSID of the host variable as described in Table 156 on page 1449.</p> <p>For XML data, sqlname can be set as follows to indicate as XML subtype:</p> <p>The length of sqlname is 8</p> <p>Bytes 1 and 2: Must be X'0000'.</p> <p>Bytes 3 and 4: May contain a CCSID.</p> <p>Bytes 5 and 6 X'0100' XML host variable (XML AS CLOB, XML AS DBCLOB, XML AS BLOB, XML AS CLOB_FILE, XML AS DBCLOB_FILE, XML AS BLOB_FILE)</p> <p>Bytes 7 and 8: Must be X'0000'.</p>

Fields in an occurrence of a secondary SQLVAR

Table 154. Field Descriptions for an Extended SQLVAR

C Name ¹⁵⁹	COBOL Name	PL/I Name	RPG Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager)	Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)
len.sqllonglen SQLLONGL SQLLONGLEN				INTEGER	The length attribute of a LOB column. For XML, the value is 0.	The length attribute of a LOB or XML host variable. The database manager ignores the SQLLEN field in the base SQLVAR for these data types. The length attribute indicates the number of bytes for a BLOB, and the number of characters for a CLOB, DBCLOB, or for XML.
*				CHAR(12)	Reserved. Provides boundary alignment for SQLDATALEN.	Reserved. Provides boundary alignment for SQLDATALEN.
*				pointer	Reserved.	Reserved.
sqldatalen SQLDATAL SQLDATALEN				pointer	Not used.	Used only for LOB host variables. If the value of this field is not null, this field points to a four-byte long buffer that contains the actual length of the LOB in bytes (even for DBCLOBs). The SQLDATA field in the matching base SQLVAR then points to the LOB data.
					If the value of this field is null, the actual length of the LOB is stored in the first four bytes pointed to by the SQLDATA field in the matching base SQLVAR, and the LOB data immediately follows the four-byte length. The actual length indicates the number of bytes for a BLOB or CLOB and the number of double-byte characters for a DBCLOB.	Regardless of whether this field is used, field SQLLONGLEN must be set.

¹⁵⁹ In this column, the lowercase name is the C Name. The first uppercase name is the PL/I and RPG Name. The second uppercase name is the COBOL Name.

Table 154. Field Descriptions for an Extended SQLVAR (continued)

C Name ¹⁵⁹ COBOL Name PL/I Name RPG Name	Field Data Type	Usage in DESCRIBE and PREPARE (set by the database manager)	Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)
sqldatatype_name SQLNAME SQLDATATYPE-NAME	VARCHAR (30)	<p>The SQLNAME field of the extended SQLVAR is set to one of the following:</p> <ul style="list-style-type: none"> • For a distinct type column, the database manager sets this to the fully qualified distinct type name. If the qualified name is longer than 30 bytes, it is truncated. • For a label, the database manager sets this to the first 20 bytes of the label. • For a column name, the database manager sets this to the column name. 	Not used.

SQLTYPE and SQLLEN

The following table shows the values that may appear in the SQLTYPE and SQLLEN fields of the SQLDA. In PREPARE and DESCRIBE, an even value of SQLTYPE means the column does not allow nulls, and an odd value means the column does allow nulls.

Note: In an SQLDA used in DESCRIBE or PREPARE statements, an odd value is returned for an expression if one operand is nullable or if the expression may result in a -2 mapping-error null value.

In FETCH, OPEN, CALL, and EXECUTE, an even value of SQLTYPE means no indicator variable is provided, and an odd value means that SQLIND contains the address of an indicator variable.

Table 155. SQLTYPE and SQLLEN values for PREPARE, DESCRIBE, FETCH, OPEN, CALL, or EXECUTE

SQLTYPE	For PREPARE and DESCRIBE		For FETCH, OPEN, CALL, and EXECUTE	
	COLUMN DATA TYPE	SQLLEN	HOST VARIABLE DATA TYPE	SQLLEN
384/385	Date ¹⁶²	10	Fixed-length character-string representation of a date	Length attribute of the host variable
388/389	Time	8	Fixed-length character-string representation of a time	Length attribute of the host variable
392/393	Timestamp	19 for TIMESTAMP(0) otherwise 20+p for TIMESTAMP(p)	Fixed-length character-string representation of a timestamp	Length attribute of the host variable

Table 155. SQLTYPE and SQLLEN values for PREPARE, DESCRIBE, FETCH, OPEN, CALL, or EXECUTE (continued)

SQLTYPE	For PREPARE and DESCRIBE		For FETCH, OPEN, CALL, and EXECUTE	
	COLUMN DATA TYPE	SQLLEN	HOST VARIABLE DATA TYPE	SQLLEN
396/397	DataLink	Length attribute of the column	DataLink	Length attribute of the host variable
400/401	Not Applicable	Not Applicable	NUL-terminated graphic string	Length attribute of the host variable
404/405	BLOB	0 ¹⁶¹	BLOB	Not used. ¹⁶¹
408/409	CLOB	0 ¹⁶¹	CLOB	Not used. ¹⁶¹
412/413	DBCLOB	0 ¹⁶¹	DBCLOB	Not used. ¹⁶¹
448/449	Varying-length character string	Length attribute of the column	Varying-length character string	Length attribute of the host variable
452/453	Fixed-length character string	Length attribute of the column	Fixed-length character string	Length attribute of the host variable
456/457	Long varying-length character string	Length attribute of the column	Long varying-length character string	Length attribute of the host variable
460/461	Not Applicable	Not Applicable	NUL-terminated character string	Length attribute of the host variable
464/465	Varying-length graphic string	Length attribute of the column	Varying-length graphic string	Length attribute of the host variable
468/469	Fixed-length graphic string	Length attribute of the column	Fixed-length graphic string	Length attribute of the host variable
472/473	Long varying-length graphic string	Length attribute of the column	Long graphic string	Length attribute of the host variable
476/477	Not Applicable	Not Applicable	PASCAL L-string	Length attribute of the host variable
480/481	Floating point	4 for single precision, 8 for double precision	Floating point	4 for single precision, 8 for double precision
484/485	Packed decimal	Precision in byte 1; scale in byte 2	Packed decimal	Precision in byte 1; scale in byte 2
488/489	Zoned decimal	Precision in byte 1; scale in byte 2	Zoned decimal	Precision in byte 1; scale in byte 2
492/493	Big integer	8 ¹⁶⁰	Big integer	8
496/497	Large integer	4 ¹⁶⁰	Large integer	4
500/501	Small integer	2 ¹⁶⁰	Small integer	2
504/505	Not Applicable	Not Applicable	DISPLAY SIGN LEADING SEPARATE	Precision in byte 1; scale in byte 2
904/905	ROWID	40	ROWID	40
908/909	Varying-length binary string	Length attribute of the column	Varying-length binary string	Length attribute of the host variable

Table 155. SQLTYPE and SQLLEN values for PREPARE, DESCRIBE, FETCH, OPEN, CALL, or EXECUTE (continued)

SQLTYPE	For PREPARE and DESCRIBE		For FETCH, OPEN, CALL, and EXECUTE	
	COLUMN DATA TYPE	SQLLEN	HOST VARIABLE DATA TYPE	SQLLEN
912/913	Fixed-length binary string	Length attribute of the column	Fixed-length binary string	Length attribute of the host variable
916/917	Not Applicable	Not Applicable	BLOB file reference variable	267
920/921	Not Applicable	Not Applicable	CLOB file reference variable	267
924/925	Not Applicable	Not Applicable	DBCLOB file reference variable	267
960/961	Not Applicable	Not Applicable	BLOB locator	4
964/965	Not Applicable	Not Applicable	CLOB locator	4
968/969	Not Applicable	Not Applicable	DBCLOB locator	4
972	Not Applicable	Not Applicable	Result set locator	8
988/989	XML	0	Not Applicable. Use XML AS CLOB, XML AS DBCLOB, or XML AS BLOB	0
996/997	Not Applicable DECFLOAT(16) DECFLOAT(34)	Not Applicable 8 16	DECFLOAT(7) ¹⁶³ DECFLOAT(16) DECFLOAT(34)	4 8 16
2452/2453	Not Applicable	Not Applicable	XML locator	4

CCSID values in SQLDATA or SQLNAME

In the OPEN, FETCH, CALL, and EXECUTE statements, the SQLNAME field of the SQLVAR element can be used to specify a CCSID for string host variables. If the SQLNAME field is used to specify a CCSID, the SQLNAME length must be set to 8. In addition, the first 4 bytes of SQLNAME must be set as described in the table below. If no CCSID is specified, the job CCSID is used.

In the DESCRIBE, DESCRIBE TABLE, and PREPARE statements, the SQLDATA field of the SQLVAR element contains the CCSID of the column of the result table if that column is a string column. The CCSID is located in bytes 3 and 4 as described in [Table 156 on page 1449](#).

¹⁶⁰ Binary numbers can be represented in the SQLDA with a length of 2, 4, or 8, or with the precision in byte 1 and the scale in byte 2. If the first byte is greater than x'00', it indicates precision and scale.

¹⁶¹ Field SQLLONGLEN in the extended SQLVAR contains the length attribute of the column.

¹⁶² Less for *JUL, *YMD, *DMY, and *MDY formats. For more information, see [Table 8 on page 71](#)

¹⁶³ Db2 does not internally store DECFLOAT(7) numbers, but it will support DECFLOAT(7) numbers from applications. A DECFLOAT(7) variable referenced in an SQL statement will be converted to DECFLOAT(16).

Table 156. CCSID values for SQLDATA or SQLNAME

Data Type	Encoding Scheme	Bytes 1 & 2	Bytes 3 & 4
Character	SBCS data	X'0000'	ccsid
Character	Mixed data	X'0000'	ccsid
Character	Bit data	X'0000'	65535
Graphic	Not Applicable	X'0000'	ccsid
Any other data type	Not Applicable	Not Applicable	Not Applicable

Unrecognized and unsupported SQLTYPES

The values that appear in the SQLTYPE field of the SQLDA are dependent on the level of data type support available at the sender as well as the receiver of the data. This is particularly important as new data types are added to the product.

New data types may or may not be supported by the sender or receiver of the data and may or may not even be recognized by the sender or receiver of the data. Depending on the situation, the new data type may be returned, or a compatible data type agreed upon by both the sender and receiver of the data may be returned or an error may result.

When the sender and receiver agree to use a compatible data type, the following indicates the mapping that will take place. This mapping will take place when at least one of the sender or receiver does not support the data type provided. The unsupported data type can be provided by either the application or the database manager.

Table 157. Compatible Data Types for Unsupported Data Types

Data Type	Compatible Data Type
BIGINT	DECIMAL(19,0)
ROWID	VARCHAR(40) FOR BIT DATA
TIMESTAMP(n)	TIMESTAMP(6)

INCLUDE SQLDA declarations

This section shows the equivalent INCLUDE SQLDA declaration for C and C++, COBOL, ILE COBOL, PL/I, and ILE RPG.

For C and C++

In C and C++, INCLUDE SQLDA declarations are equivalent to the following:

```

#ifndef SQLDASIZE
struct sqlda
{
    unsigned char  sqldaid[8];
    long          sqldabc;
    short         sqln;
    short         sqld;
    struct sqlvar
    {
        short      sqltype;
        short      sqllen;
        union {
            unsigned char *sqldata;
            long long sqld_result_set_locator;  };
        union {
            short *sqlind;
            long sqld_row_change;
            long sqld_result_set_rows;  };
        struct sqlname
        {
            short      length;
            unsigned char  data[30];
        } sqlname;
    } sqlvar[1];
};

struct sqlvar2
{
    struct
    {
        { long           sqllonglen;
        char          reserve1[28];
        } len;
        char *sqldatalen;
        struct sqldistinct_type
        {
            { short      length;
            unsigned char  data[30];
            } sqldatatype_name;
        };
    };
};

#define SQLDASIZE(n) (sizeof(struct sqlda)+(n-1) * sizeof(struct sqlvar))
#endif

```

```

Figure 14. INCLUDE SQLDA Declarations for ILE RPG

The user is responsible for the definition of SQL_NUM. SQL_NUM must be defined as a numeric constant with the dimension required for SQL_VAR.

Since RPG does not support structures within arrays, the SQLDA generates three data structures. The second and third data structures are used to setup/reference the part of the SQLDA which contains the field descriptions.

To set the field descriptions of the SQLDA the program sets up the field description in the subfields of SQLVAR (or SQLVAR2) and then does a MOVEA of SQLVAR (or SQLVAR2) to SQL_VAR, n where n is the number of the field in the SQLDA. This is repeated until all the field descriptions are set.

When the SQLDA field descriptions are to be referenced the user does a MOVEA of SQL_VAR, n to SQLVAR (or SQLVAR2) where n is the number of the field description to be processed.

Appendix E. CCSID values

The tables in this section describe the CCSIDs and conversions provided by the IBM relational database products.

For more information, see “[Character conversion](#)” on page 28.

The following list defines the symbols used in the Db2 product column in the following tables:

X

Indicates that the conversion tables exist to convert from or to that CCSID. This also implies that this CCSID can be used to tag local data.

C

Indicates that conversion tables exist to convert from that CCSID to another CCSID. This also implies that this CCSID cannot be used to tag local data, because the CCSID is in a foreign encoding scheme (for example, a PC-Data CCSID such as 850 cannot be used to tag local data in Db2 for i).

blank

Indicates that the specific product does not support the CCSID at all. Such a CCSID must not be used unless interoperability with the specific product is not necessary.

This information is current as of the publishing date of this book for the CCSIDs listed. Additional CCSIDs may have been added since the publishing date and are not in the lists below.

Table 158. Universal Character Set (UTF-8, UTF-16, and UCS-2)

CCSID	Description	z/OS	i	AIX	HP	Sun	NT	SCO	SGI	Linux
1200	UTF-16	X	X	X	X	X	X	X	X	X
1208	UTF-8 Level 3	X	X	X	X	X	X	X	X	X
13488	UCS-2 Level 1	C	X	C *	C *	C *	C *	C *	C *	C *

Note: * In Db2 LUW, 13488 is only used to tag the GRAPHIC column of eucJP and eucTW databases.

Appendix F. Db2 for i catalog views

The views contained in a Db2 for i catalog are described in this section.

The database manager maintains a set of tables containing information about the data in each relational database. These tables are collectively known as the *catalog*. The *catalog tables* contain information about tables, user-defined functions, distinct types, parameters, procedures, packages, views, indexes, aliases, sequences, variables, constraints, triggers, XSR objects, and languages supported by Db2 for i. The catalog also contains information about all relational databases that are accessible from this system.

There are three classes of catalog views:

- IBM i catalog tables and views

The IBM i catalog tables and views are modeled after the ANSI and ISO catalog views, but are not identical to the ANSI and ISO catalog views.

These tables and views exist in schemas QSYS and QSYS2.

The catalog tables and views contain information about all tables, parameters, procedures, functions, distinct types, packages, XSR objects, views, indexes, aliases, sequences, variables, triggers, and constraints in the entire relational database. When an SQL schema is created, an additional subset of these views are created into the schema that only contain information about tables, packages, views, indexes, and constraints in that schema.

- ODBC and JDBC catalog views

The ODBC and JDBC catalog views are designed to satisfy ODBC and JDBC metadata API requests. For example, SQLCOLUMNS. These views are compatible with views on Db2 LUW Version 8. These views will be modified as ODBC or JDBC enhances or modifies their metadata APIs.

These views exist in schema SYSIBM.

- ANSI and ISO catalog views

The ANSI and ISO catalog views are designed to comply with the ANSI and ISO SQL standard (the Information Schema catalog views). These views will be modified as the ANSI and ISO standard is enhanced or modified.

There are several columns in these views that are reserved for future standard enhancements.

There are two versions of these views. One is in schema INFORMATION_SCHEMA¹⁶⁴ and the other is in schema SYSIBM.

Note: Some of these views use special catalog functions as part of the view definition. These functions exist in SYSIBM and QSYS2. If these functions are used directly in applications, care should be taken because they may be incompatibly changed in future releases or fix packs.

Notes

Names in the Catalog: In general, all names stored in columns of a catalog table are undelimited and case sensitive. For example, assume the following table was created:

```
CREATE TABLE "colname"/"long_table_name"
  ("long_column_name" CHAR(10),
   INTCOL INTEGER)
```

If the following select statement is used to return information about the mapping between SQL names and system names, the following select statement could be used:

¹⁶⁴ INFORMATION_SCHEMA is the ANSI and ISO SQL standard schema name that contains catalog views. It is a synonym for QSYS2.

```

SELECT TABLE_NAME, SYSTEM_TABLE_NAME, COLUMN_NAME, SYSTEM_COLUMN_NAME
FROM QSYS2/SYSCOLUMNS
WHERE TABLE_NAME = 'long_table_name' AND
      TABLE_SCHEMA = 'colname'

```

The following rows would be returned:

TABLE_NAME	SYSTEM_TABLE_NAME	COLUMN_NAME	SYSTEM_COLUMN_NAME
long_table_name	"long0001"	long_column_name	LONG_00001
long_table_name	"long0001"	INTCOL	INTCOL

System Names in the Catalog: In general, the longer SQL column names should be used rather than the short system column names. The short system column names for IBM i catalog tables and views are explicitly maintained for compatibility with prior releases and other Db2 products. The short system column names for the ODBC and JDBC catalog views and the ANS and ISO catalog views are not explicitly maintained and may change between releases.

Null Values in the Catalog: If the information in a column is not applicable, the null value is returned. Using the table created above, the following select statement, which queries the NUMERIC_SCALE and the CHARACTER_MAXIMUM_LENGTH, would return the null value when the data was not applicable to the data type of the column.

```

SELECT COLUMN_NAME, NUMERIC_SCALE, CHARACTER_MAXIMUM_LENGTH
FROM QSYS2/SYSCOLUMNS
WHERE TABLE_NAME = 'long_table_name'      AND
      TABLE_SCHEMA = 'colname'

```

The following rows would be returned:

COLUMN_NAME	NUMERIC_SCALE	CHARACTER_MAXIMUM_LENGTH
long_column_name	?	10
INTCOL	0	?

Because numeric scale is not valid for a character column, the null value is returned for NUMERIC_SCALE for the "long_column_name" column. Because character length is not valid for a numeric column, the null value is returned for CHARACTER_MAXIMUM_LENGTH for the INTCOL column.

Install and Backup Considerations: Certain catalog tables and any views created over the catalog tables and views should be regularly saved:

- The catalog table QSYS.QADBXRDBD contains relational database information. This table should be regularly saved.
- When an ILE external function or procedure or an SQL function or procedure is restored, information is automatically inserted into these catalog tables. This does not occur for non-ILE external functions and procedures. In order to backup the definitions of non-ILE external functions or procedures, ensure that the catalog tables SYSROUTINES and SYSPARMS are saved or ensure you have a backup of the SQL source statements that were used to create these functions and procedures.
- All catalog views in the QSYS2 or SYSIBM schemas are system objects. This means that any user views created over these catalog views must be deleted when the operating system is installed. All dependent objects must be deleted as well. To avoid this requirement, you can save views before installation and then restore them afterwards.
- Catalog tables in the QSYS library are also system objects. However, the catalog tables in the QSYS library are not deleted during installation. Hence, any views created over these tables are preserved throughout the installation process.

Granting Privileges to Catalog Views: Tables and views in the catalog are like any other database tables and views. If you have authorization, you can use SQL statements to look at data in the catalog views in the same way that you retrieve data from any other table. The tables and views in the catalogs are shipped with the SELECT privilege to PUBLIC. This privilege may be revoked and the SELECT privilege granted to individual users.

QSYS Catalog Tables: Most of the catalog views are based on the following tables in the QSYS library (sometimes called the database cross reference files). These tables are not shipped with the SELECT privilege to PUBLIC and should not be used directly:

QADBCCST	QADBPKG	QADBXSFLD
QADBFDEP	QADBXCTLSD	QADBXRIGB
QADBFNST	QADBXRIGC	QADBXRIGD
QADBIFLD	QADBXRDB	QADBXRIGD
QADBKFLD	QADBXRREF	

Use of SELECT *: New columns are likely to be added to tables and views in the catalog as new functionality is implemented and as the ISO/ANSI standards evolve. For this reason, it is recommended that SELECT * not be used when accessing catalog tables and views unless your application is prepared to tolerate these new columns.

IBM i catalog tables and views

The IBM i catalog includes the views and tables in the QSYS2 schema displayed in this section.

Db2 for i name	Corresponding ANSI/ISO name	Description
"SYSCATALOGS" on page 1473	CATALOGS	Information about relational databases
"SYSCHKCST" on page 1474	CHECK_CONSTRAINTS	Information about check constraints
"SYSCOLAUTH" on page 1474	COLUMN_PRIVILEGES	Information about column privileges
"SYSCOLUMNS" on page 1475	COLUMNS	Information about column attributes
"SYSCOLUMNS2" on page 1482		Information about column attributes

“SYTRIGDEP” on page 1596	trigger_table_usage	Information about objects used in a trigger
“SYTRIGGERS” on page 1597	TRIGGERS	Information about triggers
“SYTRIGUPD” on page 1601	triggered_update_columns	Information about columns in the WHEN clause of a trigger
“SYSTYPES” on page 1601	USER_DEFINED_TYPES	Information about built-in data types and distinct types
“SYSUDTAUTH” on page 1606	UDT_PRIVILEGES	Information about type privileges
“SYSVARIABLEAUTH” on page 1606		Information about global variable privileges
“SYSVARIABLEDEP” on page 1607		Information about objects used in global variables

Db2 for i name	Corresponding ANSI/ISO name	Description
“SYSVARIABLES” on page 1608		Information about global variables
“SYSVIEWDEP” on page 1613	VIEW_TABLE_USAGE	Information about view dependencies on tables
“SYSVIEWS” on page 1614	VIEWS	Information about definition of a view
“SYSXSROBJECTAUTH” on page 1615	USAGE_PRIVILEGES	Information about XML schema privileges
“XSRANNOTATIONINFO” on page 1616		Information about annotations
“XSROBJECTCOMPONENTS” on page 1617		Information about components in an XML schema
“XSROBJECTHIERARCHIES” on page 1617		Information about XML schema document hierarchy relationships
“XSROBJECTS” on page 1618		Information about XML schemas

SYSCATALOGS

The SYSCATALOGS view contains one row for each relational database that a user can connect to. The following table describes the columns in the SYSCATALOGS view.

Table 169. SYSCATALOGS view

Column Name	System Column Name	Data Type	Description
CATALOG_NAME	LOCATION	VARCHAR(18)	Relational database name.
CATALOG_STATUS	RDBASPSTAT	CHAR(10)	Status of a relational database.
			ACTIVE The relational database is associated with an independent auxiliary storage pool (IASP) that is active, but not yet available.
			AVAILABLE The relational database is available.
			VARYOFF The relational database is associated with an independent auxiliary storage pool (IASP) that is varied off.
			VARYON The relational database is associated with an independent auxiliary storage pool (IASP) that is varied on, but not yet available.
			UNKNOWN The status of the relational database is unknown. The status of remote relational databases is always unknown.
CATALOG_TYPE	RDBTYPE	CHAR(7)	Relational database type.
			LOCAL The relational database is local to this system.
			MIRROR The relational database is defined for a Db2 Mirror relationship.
			REMOTE The relational database is on a remote system.
CATALOG_ASPGRP	RDBASPGRP	VARCHAR(10)	Independent auxiliary storage pool (IASP) name.
		Nullable	Contains the null value for the system ASP or if CATALOG_STATUS is UNKNOWN.
CATALOG_ASNUM	RDBASPNUM	VARCHAR(10)	Independent auxiliary storage pool (IASP) number.
		Nullable	Contains the null value for the system ASP or if CATALOG_STATUS is UNKNOWN.
CATALOG_TEXT	RDBTEXT	VARGRAPHIC(50) CCSID 1200	Relational database text description.
		Nullable	

SYSCHKCST

The SYSCHKCST view contains one row for each check constraint in the SQL schema. The following table describes the columns in the SYSCHKCST view.

Table 170. SYSCHKCST view

Column Name	System Column Name	Data Type	Description
CONSTRAINT_SCHEMA	DBNAME	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint
CHECK_CLAUSE	CHECK	VARGRAPHIC(2000) CCSID 1200 Nullable	Text of the check constraint clause Contains the null value if the check clause cannot be expressed without truncation.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	The rounding mode for the check constraint: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.
INSERT_ACTION	INS_ACTION	VARGRAPHIC(500) CCSID 1200 Nullable	If an insert violation action has been defined, contains the text of the ON INSERT clause. Otherwise, contains the null value.
UPDATE_ACTION	UPD_ACTION	VARGRAPHIC(500) CCSID 1200 Nullable	If an update violation action has been defined, contains the text of the ON UPDATE clause. Otherwise, contains the null value.

SYSCOLAUTH

The SYSCOLAUTH view contains one row for every privilege granted on a column. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ). Furthermore, the privilege to use a column is also acquired through privileges granted on the table.

The following table describes the columns in the SYSCOLAUTH view:

Table 171. SYSCOLAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Name of the schema
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table
COLUMN_NAME	NAME	VARCHAR(128)	Name of the column

Table 171. SYSCOLAUTH view (continued)

Column Name	System Column Name	Data Type	Description
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: UPDATE The privilege to update the column. REFERENCES The privilege to reference the column in a referential constraint.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	Contains the null value.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table or view
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	System name of the column

SYSOLUMNS

The SYSCOLUMNS view contains one row for every column of each table and view in the SQL schema (including the columns of the SQL catalog).

The following table describes the columns in the SYSCOLUMNS view:

Table 172. SYSCOLUMNS view

Column name	System Column Name	Data Type	Description
COLUMN_NAME	NAME	VARCHAR(128)	Name of the column. This will be the SQL column name if one exists; otherwise, it will be the system column name.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table or view that contains the column. This will be the SQL table or view name if one exists; otherwise, it will be the system table or view name.
TABLE_OWNER	TBCREATOR	VARCHAR(128)	The owner of the table or view.
ORDINAL_POSITION	COLNO	INTEGER	Numeric place of the column in the table or view, ordered from left to right.

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
DATA_TYPE	COLTYPE	VARCHAR(8)	Type of column: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal FLOAT Floating point; FLOAT, REAL, or DOUBLE PRECISION DECFLOAT Decimal floating-point CHAR Fixed-length character string VARCHAR Varying-length character string CLOB Character large object string GRAPHIC Fixed-length graphic string VARG Varying-length graphic string DBCLOB Double-byte character large object string BINARY Fixed-length binary string VARBIN Varying-length binary string BLOB Binary large object string DATE Date TIME Time TIMESTMP Timestamp DATALINK Datalink ROWID Row ID XML XML DISTINCT Distinct type

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
LENGTH	LENGTH	INTEGER	The length attribute of the column; or, in the case of a decimal, numeric, or nonzero precision binary column, its precision: 8 bytes BIGINT 4 bytes INTEGER 2 bytes SMALLINT Precision of number DECIMAL Precision of number NUMERIC 8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION 4 bytes FLOAT(n) where n = 1 to 24, or REAL 8 bytes DECFLOAT(16) 16 bytes DECFLOAT(34) Length of string CHAR Maximum length of string VARCHAR or CLOB Length of graphic string GRAPHIC Maximum length of graphic string VARGRAPHIC or DBCLOB Length of string BINARY Maximum length of binary string VARBINARY or BLOB 4 bytes DATE 3 bytes TIME The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP Maximum length of datalink URL and comment DATALINK 40 bytes ROWID 2147483647 bytes XML Same value as the source type DISTINCT
NUMERIC_SCALE	SCALE	INTEGER Nullable	Scale of numeric data. Contains the null value if the column is not decimal, numeric, or binary.
IS_NULLABLE	NULLS	CHAR(1)	If the column can contain null values: N No Y Yes

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
IS_UPDATABLE	UPDATES	CHAR(1)	If the column can be updated: N No Y Yes
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
HAS_DEFAULT	DEFAULT	CHAR(1)	If the column has a default value (DEFAULT clause or null capable): N No Y Yes A The column has a ROWID data type and the GENERATED ALWAYS attribute. D The column has a ROWID data type and the GENERATED BY DEFAULT attribute. E The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED ALWAYS attribute. F The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED BY DEFAULT attribute. I The column is defined with the AS IDENTITY and GENERATED ALWAYS attributes. J The column is defined with the AS IDENTITY and GENERATED BY DEFAULT attributes. Q The column is defined with the GENERATED AS ROW BEGIN attribute. R The column is defined with the GENERATED AS ROW END attribute. X The column is defined with the GENERATED AS TRANSACTION START ID attribute. a The column is defined as a generated expression using a special register. c The column is defined as a generated expression using a global variable. d The column is defined as a generated expression using DATA CHANGE OPERATION. If the column is for a view, N is returned.
COLUMN_HEADING	LABEL	VARGRAPHIC(60) CCSID 1200 Nullable	A character string supplied with the LABEL statement (column headings) Contains the null value if there is no column heading.

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
STORAGE	STORAGE	INTEGER	<p>The storage requirements for the column:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>(Precision/2) + 1 DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHAR or BINARY</p> <p>Maximum length of string + 2 VARCHAR or VARBINARY</p> <p>Maximum length of string + 29 CLOB or BLOB</p> <p>Length of string * 2 GRAPHIC</p> <p>Maximum length of string * 2 + 2 VARGRAPHIC</p> <p>Maximum length of string * 2 + 29 DBCLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>Maximum length of datalink URL and comment + 24 DATALINK</p> <p>42 bytes ROWID</p> <p>2147483647 bytes XML</p> <p>Same value as the source type DISTINCT</p> <p>Note: This column supplies the storage requirements for all data types.</p>
NUMERIC_PRECISION	PRECISION	INTEGER Nullable	<p>The precision of all numeric columns.</p> <p>Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.</p> <p>Contains the null value if the column is not numeric.</p>

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
CCSID	CCSID	INTEGER Nullable	The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK columns. Contains 65535 if the column is a BINARY, VARBINARY, BLOB, or ROWID. Contains the null value if the column is a numeric data type.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	The name of the SQL schema containing the table or view.
COLUMN_DEFAULT	DFTVALUE	VARGRAPHIC(2000) CCSID 1200 Nullable	The default value of a column, if one exists. If the default value of the column cannot be represented without truncation, then the value of the column is the string 'TRUNCATED'. The default value is stored in character form. The following special values also exist: CURRENT_DATE The default value is the current date. CURRENT_TIME The default value is the current time. CURRENT_TIMESTAMP The default value is the current timestamp. NULL The default value is the null value and DEFAULT NULL was explicitly specified. USER The default value is the current job user. special-register When column HAS_DEFAULT contains the value 'a', the name of the special register. global-variable When column HAS_DEFAULT contains the value 'c', the qualified name of the global variable. DATA CHANGE OPERATION When column HAS_DEFAULT contains the value 'd'. Contains the null value if: <ul style="list-style-type: none"> • The column has no default value. For example, if the column has an IDENTITY attribute, is a row ID, or is a row change timestamp, row begin, row end, or transaction start ID column; or • A DEFAULT value was not explicitly specified.
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the column is not numeric.

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
DATETIME_PRECISION	DATPRC	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the column is not a date, time, or timestamp.
COLUMN_TEXT	LABELTEXT	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement (column text) Contains the null value if the column has no column text.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	The system name of the column
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	The system name of the table or view
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	The system name of the schema
USER_DEFINED_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128) Nullable	The name of the schema if this is a distinct type. Contains the null value if the column is not a distinct type.
USER_DEFINED_TYPE_NAME	TYPENAME	VARCHAR(128) Nullable	The name of the distinct type. Contains the null value if the column is not a distinct type.
IS_IDENTITY	IDENTITY	VARCHAR(3)	This column identifies whether the column is an identity column. NO The column is not an identity column. YES The column is an identity column.
IDENTITY_GENERATION	GENERATED	VARCHAR(10) Nullable	This column identifies whether the column is GENERATED ALWAYS or GENERATED BY DEFAULT. ALWAYS The column value is always generated. BY DEFAULT The column value is generated by default. Contains the null value if the column is not a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression.
IDENTITY_START	START	DECIMAL(31,0) Nullable	Starting value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_INCREMENT	INCREMENT	DECIMAL(31,0) Nullable	Increment value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MINIMUM	MINVALUE	DECIMAL(31,0) Nullable	Minimum value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MAXIMUM	MAXVALUE	DECIMAL(31,0) Nullable	Maximum value of the identity column. Contains the null value if the column is not an IDENTITY column.

Table 172. SYSCOLUMNS view (continued)

Column name	System Column Name	Data Type	Description
IDENTITY_CYCLE	CYCLE	VARCHAR(3) Nullable	This column identifies whether the identity column values will continue to be generated after the minimum or maximum value has been reached. NO Values will not continue to be generated. YES Values will continue to be generated. Contains the null value if the column is not an IDENTITY column.
IDENTITY_CACHE	CACHE	INTEGER Nullable	Specifies the number of identity values that may be preallocated for faster access. Zero indicates that the values will not be preallocated. Contains the null value if the column is not an IDENTITY column.
IDENTITY_ORDER	ORDER	VARCHAR(3) Nullable	Specifies whether the identity values must be generated in order of the request. NO Values do not need to be generated in order of the request. YES Values must be generated in order of the request. Contains the null value if the column is not an IDENTITY column.
COLUMN_EXPRESSION	EXPRESSION	DBCLOB(2097152) CCSID 1200 Nullable	If the column is an expression, contains the expression. Contains the null value if the column is not an expression.
HIDDEN	HIDDEN	CHAR(1)	Specifies whether the column is included in an implicit column list. P Partially hidden. N Not hidden.
HAS_FLDPROC	FLDPROC	CHAR(1)	Specifies whether the column has a field procedure. N Column does not have a field procedure. Y Column has a field procedure.

SYSCOLUMNS2

The SYSCOLUMNS2 view contains one row for every column of each table and view in the SQL schema (including the columns of the SQL catalog).

For information related to a single table or view, a query that uses SYSCOLUMNS2 will typically perform better than querying SYSCOLUMNS. SYSCOLUMNS2 also contains a few more column attributes than SYSCOLUMNS.

The following table describes the columns in the SYSCOLUMNS2 view:

Table 173. SYSCOLUMNS2 view

Column name	System Column Name	Data Type	Description
COLUMN_NAME	NAME	VARCHAR(128)	Name of the column. This will be the SQL column name if one exists; otherwise, it will be the system column name.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table or view that contains the column. This will be the SQL table or view name if one exists; otherwise, it will be the system table or view name.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
TABLE_OWNER	TBCREATOR	VARCHAR(128)	The owner of the table or view.
ORDINAL_POSITION	COLNO	INTEGER	Numeric place of the column in the table or view, ordered from left to right.
DATA_TYPE	COLTYPE	VARCHAR(8)	Type of column: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal FLOAT Floating point; FLOAT, REAL, or DOUBLE PRECISION DECFLOAT Decimal floating-point CHAR Fixed-length character string VARCHAR Varying-length character string CLOB Character large object string GRAPHIC Fixed-length graphic string VARG Varying-length graphic string DBCLOB Double-byte character large object string BINARY Fixed-length binary string VARBIN Varying-length binary string BLOB Binary large object string DATE Date TIME Time TIMESTMP Timestamp DATALINK Datalink ROWID Row ID XML XML DISTINCT Distinct type

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
LENGTH	LENGTH	INTEGER	The length attribute of the column; or, in the case of a decimal, numeric, or nonzero precision binary column, its precision: 8 bytes BIGINT 4 bytes INTEGER 2 bytes SMALLINT Precision of number DECIMAL Precision of number NUMERIC 8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION 4 bytes FLOAT(n) where n = 1 to 24, or REAL 8 bytes DECFLOAT(16) 16 bytes DECFLOAT(34) Length of string CHAR Maximum length of string VARCHAR or CLOB Length of graphic string GRAPHIC Maximum length of graphic string VARGRAPHIC or DBCLOB Length of string BINARY Maximum length of binary string VARBINARY or BLOB 4 bytes DATE 3 bytes TIME The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP Maximum length of datalink URL and comment DATALINK 40 bytes ROWID 2147483647 bytes XML Same value as the source type DISTINCT
NUMERIC_SCALE	SCALE	INTEGER Nullable	Scale of numeric data. Contains the null value if the column is not decimal, numeric, or binary.
IS_NULLABLE	NULLS	CHAR(1)	If the column can contain null values: N No Y Yes

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
IS_UPDATABLE	UPDATES	CHAR(1)	If the column can be updated: N No Y Yes
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
HAS_DEFAULT	DEFAULT	CHAR(1)	If the column has a default value (DEFAULT clause or null capable): N No Y Yes A The column has a ROWID data type and the GENERATED ALWAYS attribute. D The column has a ROWID data type and the GENERATED BY DEFAULT attribute. E The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED ALWAYS attribute. F The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED BY DEFAULT attribute. I The column is defined with the AS IDENTITY and GENERATED ALWAYS attributes. J The column is defined with the AS IDENTITY and GENERATED BY DEFAULT attributes. Q The column is defined with the GENERATED AS ROW BEGIN attribute. R The column is defined with the GENERATED AS ROW END attribute. X The column is defined with the GENERATED AS TRANSACTION START ID attribute. a The column is defined as a generated expression using a special register. c The column is defined as a generated expression using a global variable. d The column is defined as a generated expression using DATA CHANGE OPERATION. If the column is for a view, N is returned.
COLUMN_HEADING	LABEL	VARGRAPHIC(60) CCSID 1200 Nullable	A character string supplied with the LABEL statement (column headings) Contains the null value if there is no column heading.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
STORAGE	STORAGE	INTEGER	<p>The storage requirements for the column:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>(Precision/2) + 1 DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHAR or BINARY</p> <p>Maximum length of string + 2 VARCHAR or VARBINARY</p> <p>Maximum length of string + 29 CLOB or BLOB</p> <p>Length of string * 2 GRAPHIC</p> <p>Maximum length of string * 2 + 2 VARGRAPHIC</p> <p>Maximum length of string * 2 + 29 DBCLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>Maximum length of datalink URL and comment + 24 DATALINK</p> <p>42 bytes ROWID</p> <p>2147483647 bytes XML</p> <p>Same value as the source type DISTINCT</p> <p>Note: This column supplies the storage requirements for all data types.</p>
NUMERIC_PRECISION	PRECISION	INTEGER Nullable	<p>The precision of all numeric columns.</p> <p>Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.</p> <p>Contains the null value if the column is not numeric.</p>

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
CCSID	CCSID	INTEGER Nullable	The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK columns. Contains 65535 if the column is a BINARY, VARBINARY, BLOB, or ROWID. Contains the null value if the column is a numeric data type.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	The name of the SQL schema containing the table or view.
COLUMN_DEFAULT	DFTVALUE	VARGRAPHIC(2000) CCSID 1200 Nullable	The default value of a column, if one exists. If the default value of the column cannot be represented without truncation, then the value of the column is the string 'TRUNCATED'. The default value is stored in character form. The following special values also exist: CURRENT_DATE The default value is the current date. CURRENT_TIME The default value is the current time. CURRENT_TIMESTAMP The default value is the current timestamp. NULL The default value is the null value and DEFAULT NULL was explicitly specified. USER The default value is the current job user. special-register When column HAS_DEFAULT contains the value 'a', the name of the special register. global-variable When column HAS_DEFAULT contains the value 'c', the qualified name of the global variable. DATA CHANGE OPERATION When column HAS_DEFAULT contains the value 'd'. Contains the null value if: <ul style="list-style-type: none"> • The column has no default value. For example, if the column has an IDENTITY attribute, is a row ID, or is a row change timestamp, row begin, row end, or transaction start ID column; or • A DEFAULT value was not explicitly specified.
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the column is not numeric.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
DATETIME_PRECISION	DATPRC	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds).
			Contains the null value if the column is not a date, time, or timestamp.
COLUMN_TEXT	LABELTEXT	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement (column text) Contains the null value if the column has no column text.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	The system name of the column
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	The system name of the table or view
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	The system name of the schema
USER_DEFINED_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128) Nullable	The name of the schema if this is a distinct type. Contains the null value if the column is not a distinct type.
USER_DEFINED_TYPE_NAME	TYPENAME	VARCHAR(128) Nullable	The name of the distinct type. Contains the null value if the column is not a distinct type.
IS_IDENTITY	IDENTITY	VARCHAR(3)	This column identifies whether the column is an identity column. NO The column is not an identity column. YES The column is an identity column.
IDENTITY_GENERATION	GENERATED	VARCHAR(10) Nullable	This column identifies whether the column is GENERATED ALWAYS or GENERATED BY DEFAULT. ALWAYS The column value is always generated. BY DEFAULT The column value is generated by default. Contains the null value if the column is not a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression.
IDENTITY_START	START	DECIMAL(31,0) Nullable	Starting value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_INCREMENT	INCREMENT	DECIMAL(31,0) Nullable	Increment value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MINIMUM	MINVALUE	DECIMAL(31,0) Nullable	Minimum value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MAXIMUM	MAXVALUE	DECIMAL(31,0) Nullable	Maximum value of the identity column. Contains the null value if the column is not an IDENTITY column.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
IDENTITY_CYCLE	CYCLE	VARCHAR(3) Nullable	This column identifies whether the identity column values will continue to be generated after the minimum or maximum value has been reached. NO Values will not continue to be generated. YES Values will continue to be generated. Contains the null value if the column is not an IDENTITY column.
IDENTITY_CACHE	CACHE	INTEGER Nullable	Specifies the number of identity values that may be preallocated for faster access. Zero indicates that the values will not be preallocated. Contains the null value if the column is not an IDENTITY column.
IDENTITY_ORDER	ORDER	VARCHAR(3) Nullable	Specifies whether the identity values must be generated in order of the request. NO Values do not need to be generated in order of the request. YES Values must be generated in order of the request. Contains the null value if the column is not an IDENTITY column.
COLUMN_EXPRESSION	EXPRESSION	DBCLOB(2097152) CCSID 1200 Nullable	If the column is an expression, contains the expression. Contains the null value if the column is not an expression.
HIDDEN	HIDDEN	CHAR(1)	Specifies whether the column is included in an implicit column list. P Partially hidden. N Not hidden.
HAS_FLDPROC	FLDPROC	CHAR(1)	Specifies whether the column has a field procedure. N Column does not have a field procedure. Y Column has a field procedure.
INLINE_LENGTH	ALLOCATE	INTEGER Nullable	Specifies the allocated length (ALLOCATE) for a varying length column. Contains the null value if the column is not varying length.
NORMALIZE	NORMALIZE	CHAR(1) Nullable	Specifies whether the column data should be normalized when passed from the application. 0 Column should not be normalized. 1 Column should be normalized. Contains the null value if the column does not contain Unicode data.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
DATALINK_LINK_CONTROL	DL_LINKC	CHAR(1) Nullable	Specifies whether a check will be performed to determine if the DATALINK column's linked files exist. 0 No check will be performed. 1 A check will be performed. Contains the null value if the data type of the column is not DATALINK.
DATALINK_INTEGRITY	DL_INTEG	CHAR(1) Nullable	Specifies the level of integrity of the link between the DATALINK value and the linked files. 0 ALL Contains the null value if the data type of the column is not DATALINK or if the datalink has NO LINK CONTROL.
DATALINK_READ_PERMISSION	DL_READP	CHAR(1) Nullable	Specifies how permission to read the file specified in the DATALINK value is determined. 0 FS 1 DB Contains the null value if the data type of the column is not DATALINK or if the datalink has NO LINK CONTROL.
DATALINK_WRITE_PERMISSION	DL_WRITEP	CHAR(1) Nullable	Specifies how permission to write to the file specified in the DATALINK value is determined. 0 FS 1 BLOCKED Contains the null value if the data type of the column is not DATALINK or if the datalink has NO LINK CONTROL.
DATALINK_RECOVERY	DL_RECOVER	CHAR(1) Nullable	Specifies whether point in time recovery of the linked files of the DATALINK column is supported. 0 NO Contains the null value if the data type of the column is not DATALINK or if the datalink has NO LINK CONTROL.
DATALINK_UNLINK_CONTROL	DL_UNLINKC	CHAR(1) Nullable	Specifies the action the DataLink File Manager will take when a file is unlinked. 0 RESTORE 1 DELETE Contains the null value if the data type of the column is not DATALINK or if the datalink has NO LINK CONTROL.
DDS_TYPE	DDS_TYPE	CHAR(1) Nullable	Specifies the Data Description Specification (DDS) data type for the column. See the following link for the list DDS data types: https://www.ibm.com/support/knowledgecenter/ssw_ibm_i_74/rzakb/ldata.htm

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
SECURE	SECURE	CHAR(1) Nullable	Specifies whether the column contains data that should be secured in a database monitor or plan cache. 0 The column does not contain data that needs to be secured in a database monitor or plan cache. 1 The column contains data that needs to be secured in a database monitor or plan cache.
DATE_FORMAT	DATFMT	CHAR(3) Nullable	Date format for the column. Contains the null value if this column is not a date.
DATE_SEPARATOR	DATSEP	CHAR(1) Nullable	Date separator for the column. Contains the null value if this column is not a date or if there is no separator value.
TIME_FORMAT	TIMFMT	CHAR(3) Nullable	Time format for the column. Contains the null value if this column is not a time.
TIME_SEPARATOR	TIMSEP	CHAR(1) Nullable	Time separator for the column. Contains the null value if this column is not a time or if there is no separator value.
REFERENCE_LIBRARY	REFFLD_LIB	VARCHAR(10) Nullable	Library for the reference field. Contains the null value if there is no reference information for this column.
REFERENCE_FILE	REFFLD_FIL	VARCHAR(10) Nullable	File for the reference field. Contains the null value if there is no reference information for this column.
REFERENCE_FORMAT	REFFLD_FMT	VARCHAR(10) Nullable	Record format name for the reference field. Contains the null value if there is no reference information for this column.
REFERENCE_FIELD	REFFLD	VARCHAR(10) Nullable	Reference field name Contains the null value if there is no reference information for this column.
EDIT_CODE	EDTCDE	CHAR(1) Nullable	The edit code for this column. Contains the null value if there is no edit code.
EDIT_CODE_FILL	EDTCDEFILL	CHAR(1) Nullable	Contains an * if the edit code uses asterisk fill. Any other character is the floating currency symbol. Contains the null value if there is no edit code or if there is no fill character.
EDIT_WORD	EDTWRD	VARCHAR(65) Nullable	The edit word for this column. Contains the null value if there is no edit word.
COLUMN_USAGE	USAGE	VARCHAR(5)	Usage for the column. BOTH The column can be used for both input and output. INPUT The column can be used for input only. This means the data can be read but not changed.
JOIN_REFERENCE	JREF	INTEGER Nullable	For columns whose names are specified in more than one physical file, this value identifies which physical file contains the field. Contains the null value if there is no join reference value.

Table 173. SYSCOLUMNS2 view (continued)

Column name	System Column Name	Data Type	Description
INTERNAL_FIELD_NAME	FIELD_I	VARCHAR(10) Nullable	Internal field name. The name of the physical format field. If this is a logical format, the name of the physical field on which the logical field is based. Contains the null value if there is no internal field name.
BUFFER_LENGTH	BUF_LEN	INTEGER	The length (number of bytes) of the column in the record buffer.
BUFFER_POSITION	BUF_POS	INTEGER	The start position of the column in the record buffer.

SYSCOLUMNS2_SESSION

The SYSCOLUMNS2_SESSION view contains one row for every column of each table and view in the SESSION (or QTEMP) schema.

The columns returned by the SYSCOLUMNS2_SESSION view are identical to the columns in the SYSCOLUMNS2 view. See “[SYSCOLUMNS2](#)” on page 1482.

SYSCOLUMNSTAT

The SYSCOLUMNSTAT view contains one row for every column in a table partition or table member that has a column statistics collection. If the table is a distributed table, the partitions that reside on other database nodes are not contained in this catalog view.

They are contained in the catalog views of the other database nodes. The following table describes the columns in the SYSCOLUMNSTAT view:

Table 174. SYSCOLUMNSTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
PARTITION_NUMBER	PARTNBR	INTEGER Nullable	The partition number of this partition. If the table is a distributed table, contains null.
NUMBER_DISTRIBUTED_PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
NUMBER_COLUMN_NAMES	NBRCOLS	INTEGER	Number of column names in this collection. If only individual column statistics are wanted, only select rows where NUMBER_COLUMN_NAMES is one. Currently, only one name is returned.
COLUMN_NAME	COLNAME	VARCHAR(1280)	Name of the column(s). Up to 10 columns may be returned. Currently, only one name is returned.

Table 174. SYSCOLUMNSTAT view (continued)

Column name	System Column Name	Data Type	Description
NUMBER_DISTINCT_VALUES	COLCARD	BIGINT	Number of distinct values in the column. This is an estimated value determined by the statistics engine at the time that the column statistics were last collected. Contains -1 if statistics are not collected.
HIGH2KEY	HIGH2KEY	VARCHAR(254)	Not applicable for Db2 for i. Contains the empty string.
LOW2KEY	LOW2KEY	VARCHAR(254)	Not applicable for Db2 for i. Contains the empty string.
AVERAGE_COLUMN_LENGTH	AVGCOLLEN	INTEGER	The average length of all values stored in the column for this partition. For varying-length character and binary strings, this is the number of bytes of data. For varying-length graphic strings, this is the number of bytes divided by 2. For fixed-length columns, this is the length attribute of the column.
MAXIMUM_COLUMN_LENGTH	MAXCOLLEN	INTEGER	The maximum length of any value stored in the column for this partition. For varying-length character and binary strings, this is the number of bytes of data. For varying-length graphic strings, this is the number of bytes divided by 2. For fixed-length columns, this is the length attribute of the column.
LENGTH_AT_90TH_PERCENTILE	LEN_AT_90P	INTEGER Nullable	The length where at least 90 percent of the rows in the partition have values in this column with an actual length less than or equal to this length value. Up to 10 percent of the rows exceed this length. This information can help guide the use of the ALLOCATE clause for varying-length columns. A value of 0 is returned if this information has not been collected. NULL if not a varying-length column.
OVERFLOW_ROWS	OVERFLOW	BIGINT Nullable	The number of rows for this partition where the column overflows the fixed storage defined by the ALLOCATE clause. NULL if not a varying-length column.
NUMBER_NULLS	NUMNULLS	BIGINT	The estimated number of NULL values. -1 if statistics are not collected.
SUB_COUNT	SUB_COUNT	SMALLINT	Not applicable for Db2 for i. Will always be -1.
SUB_DELIM_LENGTH	SUBDLENGTH	SMALLINT	Not applicable for Db2 for i. Will always be -1.
NUMBER_HISTOGRAM_RANGES	NQUANTILES	INTEGER	Number of histogram ranges available for this statistics collection. The actual histogram range values can be obtained using the List Statistics Collection Details (QDBSTLDS, QdbstListDetailStatistics) API. Contains -1 if statistics are not collected.
NUMBER_MOST_FREQUENT_VALUES	NMOSFREQ	INTEGER	Number of most frequent values available. The actual most frequent values can be obtained using the List Statistics Collection Details (QDBSTLDS, QdbstListDetailStatistics) API. Contains -1 if statistics are not collected.
AVGDISTINCTPERPAGE	AVGDSTPAGE	DOUBLE Nullable	Not applicable for Db2 for i. Will always be NULL.
PAGEVARIANCERATIO	PVARRATIO	DOUBLE Nullable	Not applicable for Db2 for i. Will always be NULL.
STATISTICS_NAME	STATNAME	VARCHAR(128) Nullable	Unique name of this statistics collection for this table partition. NULL if statistics are not collected.
INTERNAL_STATISTICS_ID	STATID	VARCHAR(16) FOR BIT DATA Nullable	Internal statistics identifier of this statistics collection for this table partition. NULL if statistics are not collected.
STATISTIC_CREATED	STATCREATE	TIMESTAMP Nullable	Timestamp when the statistics collection was created. NULL if statistics are not collected.

Table 174. SYSCOLUMNSTAT view (continued)

Column name	System Column Name	Data Type	Description
STATISTIC_CREATOR	STATCUSER	VARCHAR(128) Nullable	User that created the statistic collection. *SYS if the system created the statistic collection. NULL if statistics are not collected.
STATISTIC_LAST_UPDATED	UPDATEDTS	TIMESTAMP Nullable	Timestamp when the statistics collection was last updated. NULL if statistics are not collected.
STATISTIC_UPDATER	STATUUSER	VARCHAR(128) Nullable	User that last updated the statistic collection. *SYS if the system automatically updated the statistic collection. NULL if statistics are not collected.
STATISTICS_SIZE	STATSIZE	BIGINT Nullable	Size of the statistics collection for this table partition. NULL if statistics are not collected.
AGING_MODE	AGING_MODE	VARCHAR(10) Nullable	Indicates whether the system can automatically age or remove statistics collections for this table partition. *SYS The statistic collection will be automatically refreshed or removed by the system when necessary. *USER The statistic collection will only be refreshed or removed when explicitly requested by the user.
AGING_STATUS	AGING_STS	CHAR(1) Nullable	Indicates how current the statistics collection is for this table partition. 0 There are no indications that the statistics data needs to be refreshed. 1 There are indications that the statistics data needs to be refreshed. NULL if statistics are not collected.
BLOCK_OPTION	BLKOPTION	CHAR(1) Nullable	Indicates whether automatic statistics collection create requests are allowed for this table partition. 0 Automatic system initiated statistics collections are not blocked. 1 Automatic system initiated statistics collections are blocked.
CURRENT_LAST_CHANGE	UPDATED	TIMESTAMP Nullable	Timestamp when the data in the table partition was last changed. NULL if statistics are not collected.
CURRENT_ROWS	CURROWS	BIGINT Nullable	Current number of valid rows in the table partition. NULL if statistics are not collected.
CURRENT_DELETED_ROWS	CURDELROWS	BIGINT Nullable	Current number of deleted rows in the table partition. NULL if statistics are not collected.
CURRENT_DATA_CHANGES	CURDATACHG	BIGINT Nullable	The number of inserts, updates, and deletes that have ever occurred to this table partition. NULL if statistics are not collected.
STATISTICS_ROWS	STATROWS	BIGINT Nullable	Number of valid rows in the table partition at the time the statistic was collected. NULL if statistics are not collected.
STATISTICS_DELETED_ROWS	STATDELROW	BIGINT Nullable	Number of deleted rows in the table partition at the time the statistic was collected. NULL if statistics are not collected.
STATISTICS_DATA_CHANGES	STATDATCHG	BIGINT Nullable	Number of inserts, updates, and deletes that had occurred to the table partition at the time the statistic was collected. NULL if statistics are not collected.

Table 174. SYSCOLUMNSTAT view (continued)

Column name	System Column Name	Data Type	Description
TRANSLATION_ATTRIBUTES	TRANSATRS	VARCHAR(10) Nullable	Indicates the type of translations that were used on data values when the statistic was collected. 0 Unique weight translation. 1 Shared weight translation. 9 No translation.
			If multiple columns are used in this collection, multiple translations are possible. Currently, only one translation is returned.
TRANSLATION_TABLES	TRANSTBLS	VARCHAR(210) Nullable	Qualified names of the translation tables, if translation tables were used on the statistic collection. The empty string is returned if no translation table was used. NULL if statistics are not collected. If multiple columns are used in this collection, multiple translation tables are possible. Currently, only one translation table is returned.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.
SYSTEM_COLUMN_NAME	SYS_CNAME	VARCHAR(100)	System column name. An array of up to 10 names are possible. Currently, only one name is returned.

SYSCONTROLS

The SYSCONTROLS view contains one row for each row permission or column mask defined by the CREATE PERMISSION or CREATE MASK statements.

The following table describes the columns in the SYSCONTROLS view:

Table 175. SYSCONTROLS view

Column Name	System Column Name	Data Type	Description
RCAC_SCHEMA	SCHEMA	VARCHAR(128)	Schema name of the row permission or column mask.
RCAC_NAME	NAME	VARCHAR(128)	Name of the row permission or column mask.
RCAC_OWNER	CREATOR	VARCHAR(128)	Creator of the row permission or column mask.
TABLE_SCHEMA	TBSchema	VARCHAR(128)	Schema name of the table for which the row permission or column mask is defined.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table for which the row permission or column mask is defined.
TBCORRELATION	TBCORRNAME	VARCHAR(128)	The correlation name of the table for which the row permission or column mask is defined. If not specified, a value is generated.
COLUMN_NAME	COLNAME	VARCHAR(128)	Column name for which the column mask is defined. Contains a blank for a row permission.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	The system name of the column. Contains a blank for a row permission
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	The system name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	The system name of the schema.

Table 175. SYSCONTROLS view (continued)

Column Name	System Column Name	Data Type	Description
CONTROL_TYPE	CONTROLTYP	CHAR(1)	Indicates the type of access control: R Row permission M Column mask
ENFORCED	ENFORCED	CHAR(1)	Indicates the type of access enforced by the row permission. Column mask is always 'A': A All access
IMPLICIT	IMPLICIT	CHAR(1)	Indicates whether the row permission was implicitly created: N The row permission was not implicitly created or this is a column mask. Y Row permission was implicitly created.
ENABLE	ENABLE	CHAR(1)	Indicates whether the row permission or the column mask is enabled for access control: N Not enabled Y Enabled
CREATE_TIME	CREATEDTS	TIMESTAMP	Identifies the timestamp when the row permission or column mask was created.
LAST_ALTERED	ALTERDTS	TIMESTAMP Nullable	Identifies the timestamp when the row permission or column mask was last changed. Contains the null value if it has never been altered.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
LABEL	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string provided by the LABEL statement. Contains the null value if a label does not exist.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
RULETEXT	RULETEXT	DBCLOB(2M) CCSID 1200	The source text of the search condition or expression portion of the CREATE PERMISSION or CREATE MASK statement.

SYSCONTROLSDEP

The SYSCONTROLSDEP view records the dependencies of row permissions and column masks.

The following table describes the columns in the SYSCONTROLSDEP view:

Table 176. SYSCONTROLSDEP view

Column Name	System Column Name	Data Type	Description
RCAC_SCHEMA	SCHEMA	VARCHAR(128)	Schema name of the row permission or column mask.
RCAC_NAME	NAME	VARCHAR(128)	Name of the row permission or column mask.
CONTROL_TYPE	CONTROLTYP	CHAR(1)	Indicates the type of access control: R Row permission M Column mask

Table 176. SYSCONTROLSDEP view (continued)

Column Name	System Column Name	Data Type	Description
OBJECT_SCHEMA	BSCHEMA	VARCHAR(128)	Name of the schema that contains the object.
OBJECT_NAME	BNAME	VARCHAR(128)	Name of the object the row permission or column mask is dependent on.
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object referenced in the row permission or column mask.
			COLUMN The object is a column in a table.
			FUNCTION The object is a function.
			MATERIALIZED QUERY TABLE The object is a materialized query table.
			SEQUENCE The object is a sequence.
			TABLE The object is a table.
			TYPE The object is a distinct type.
			VARIABLE The object is a variable.
			VIEW The object is a view.
COLUMN_NAME	BCOLNAME	VARCHAR(128)	Column name for the object when OBJECT_TYPE has a value of 'COLUMN'. In this case, OBJECT_NAME contains the table name for the column. Contains a blank if object is not a column.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	The system name of the table upon which the row permission or column mask is defined.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	The system name of the schema of the table upon which the row permission or column mask is defined.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
PARM_SIGNATURE	SIGNATURE	BLOB(3M)	This column identifies the routine signature. Contains the null value if the object is not a routine.

SYSCST

The SYSCST view contains one row for each constraint in the SQL schema.

The following table describes the columns in the SYSCST view:

Table 177. SYSCST view

Column Name	System Column Name	Data Type	Description
CONSTRAINT_SCHEMA	CDBNAME	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.
CONSTRAINT_TYPE	TYPE	VARCHAR(11)	Constraint Type <ul style="list-style-type: none"> • CHECK • UNIQUE • PRIMARY KEY • FOREIGN KEY
TABLE_SCHEMA	TDBNAME	VARCHAR(128)	Name of the schema containing the table.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table which the constraint is created over. This will be the SQL table name if it exists; otherwise, it will be the system table name.

Table 177. SYSCST view (continued)

Column Name	System Column Name	Data Type	Description
IS_DEFERRABLE	ISDEFER	VARCHAR(3)	Indicates whether the constraint checking can be deferred. Will always be 'NO'.
INITIALLY_DEFERRED	INITDEFER	VARCHAR(3)	Indicates whether the constraint was defined as initially deferred. Will always be 'NO'.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the table.
CONSTRAINT_KEYS	COLCOUNT	SMALLINT Nullable	Specifies the number of key columns if this is a UNIQUE, PRIMARY KEY, or FOREIGN KEY constraint. Contains the null value if the constraint is a CHECK constraint.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
CONSTRAINT_STATE	CST_STATE	VARCHAR(11)	Indicates whether the constraint is established or defined: ESTABLISHED The referential constraint is established. The parent table exists. DEFINED The referential constraint is defined. The parent table does not exist.
ENABLED	ENABLED	VARCHAR(3) Nullable	Indicates whether the constraint is enabled: NO The constraint is disabled. YES The constraint is enabled. Contains the null value if the constraint is defined or is a unique constraint.
CHECK_PENDING	CHECKFLAG	VARCHAR(3) Nullable	Indicates whether the constraint is in check pending state: NO The constraint is not in check pending. YES The constraint is in check pending. Contains the null value if the constraint is defined, disabled, or is a unique constraint.
CONSTRAINT_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string provided with the LABEL statement. Contains the null value if there is no label.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.

SYSCSTCOL

The SYSCSTCOL view records the columns on which constraints are defined. There is one row for every column in a unique, primary key, and check constraint and the referencing columns of a referential constraint.

The following table describes the columns in the SYSCSTCOL view:

Table 178. SYSCSTCOL view

Column Name	System Column Name	Data Type	Description
TABLE_SCHEMA	TDBNAME	VARCHAR(128)	Name of the SQL schema that contains the table the constraint is dependent on.

Table 178. SYSCSTCOL view (continued)

Column Name	System Column Name	Data Type	Description
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table the constraint is dependent on. This is the SQL table name if it exists; otherwise, it is the system table name.
COLUMN_NAME	COLUMN	VARCHAR(128)	Column that the constraint was created over. This is the SQL column name if it exists; otherwise, it is the system column name.
CONSTRAINT_SCHEMA	CDBNAME	VARCHAR(128)	Name of the schema of the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	System name of the column.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the table.
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.

SYSCSTDEP

The SYSCSTDEP view records the tables on which constraints are defined.

The following table describes the columns in the SYSCSTDEP view:

Table 179. SYSCSTDEP view

Column Name	System Column Name	Data Type	Description
TABLE_SCHEMA	TDBNAME	VARCHAR(128)	Name of the SQL schema that contains the table on which the constraint is dependent
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table on which the constraint is dependent. This is the SQL table name if it exists otherwise it is the system table name.
CONSTRAINT_SCHEMA	CDBNAME	VARCHAR(128)	Name of the schema of the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the table.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.

SYSDUMMY1

The SYSDUMMY1 table contains exactly one row. It is used for SQL statements in which a table reference is required, but the contents of the table are not important.

The schema is SYSIBM.

The following table describes the column in the SYSDUMMY1 table:

Table 180. SYSDUMMY1 table

Column name	System Column Name	Data Type	Description
IBMRREQD	IBMRREQD	VARCHAR(1)	Always contains a value of Y.

SYSFIELDS

The SYSFIELDS view contains one row for every column that has a field procedure.

The column attributes in SYSFIELDS describe the internal column attributes defined by the field procedure. The following table describes the columns in the SYSFIELDS view:

Table 181. SYSFIELDS view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	DBNAME	VARCHAR(128)	The name of the SQL schema containing the table.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table that contains the column. This will be the SQL table name if one exists; otherwise, it will be the system table name.
COLUMN_NAME	NAME	VARCHAR(128)	Name of the column. This will be the SQL column name if one exists; otherwise, it will be the system column name.
ORDINAL_POSITION	COLNO	INTEGER	Numeric place of the column in the table, ordered from left to right.
DATA_TYPE	COLTYPE	VARCHAR(8)	Type of column: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal FLOAT Floating point; FLOAT, REAL, or DOUBLE PRECISION DECFLOAT Decimal floating-point CHAR Fixed-length character string VARCHAR Varying-length character string CLOB Character large object string GRAPHIC Fixed-length graphic string VARG Varying-length graphic string DBCLOB Double-byte character large object string BINARY Fixed-length binary string VARBIN Varying-length binary string BLOB Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML DISTINCT Distinct type

Table 181. SYSFIELDS view (continued)

Column name	System Column Name	Data Type	Description
LENGTH	LENGTH	INTEGER	The length attribute of the column; or, in the case of a decimal, numeric, or nonzero precision binary column, its precision: 8 bytes BIGINT 4 bytes INTEGER 2 bytes SMALLINT Precision of number DECIMAL Precision of number NUMERIC 8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION 4 bytes FLOAT(n) where n = 1 to 24, or REAL 8 bytes DECFLOAT(16) 16 bytes DECFLOAT(34) Length of string CHAR Maximum length of string VARCHAR or CLOB Length of graphic string GRAPHIC Maximum length of graphic string VARGRAPHIC or DBCLOB Length of string BINARY Maximum length of binary string VARBINARY or BLOB 4 bytes DATE 3 bytes TIME The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP Maximum length of datalink URL and comment DATALINK 40 bytes ROWID 2147483647 bytes XML Same value as the source type DISTINCT
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
NUMERIC_SCALE	SCALE	INTEGER Nullable	Scale of numeric data. Contains the null value if the column is not decimal, numeric, or binary.

Table 181. SYSFIELDS view (continued)

Column name	System Column Name	Data Type	Description
NUMERIC_PRECISION	PRECISION	INTEGER Nullable	The precision of all numeric columns. Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if the column is not numeric.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the column is not numeric.
CCSID	CCSID	INTEGER Nullable	The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK columns. Contains 65535 if the column is a BINARY, VARBINARY, BLOB, or ROWID. Contains the null value if the column is a numeric data type.
DATETIME_PRECISION	DATPRC	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the column is not a date, time, or timestamp.
FIELD_PROC	FLDPROC	VARCHAR(279) Nullable	The name of the procedure.
PARMLIST	PARMLIST	DBCLOB(1M) CCSID 1200 Nullable	The parameter list following FIELDPROC in the statement that defined the field procedure with insignificant blanks removed.
EXITPARM	EXITPARM	BLOB(1M) Nullable	The parameter value block of the field procedure. This is the control block passed to the field procedure when it is invoked.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	The system name of the column
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	The system name of the table
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	The system name of the schema

SYSFILES

The SYSFILES view contains one row for every Db2 for i database file, including native files. This view includes attributes not returned by QSYS2.SYSTABLES.

See [QSYS2.SYSFILES](#) for a description of the view.

SYSFUNCS

The SYSFUNCS view contains one row for each function created by the CREATE FUNCTION statement.

The following table describes the columns in the SYSFUNCS view:

Table 182. SYSFUNCS view

Column Name	System Column Name	Data Type	Description
SPECIFIC_SCHEMA	SPECSCHEMA	VARCHAR(128)	Schema name of the routine (function) instance.
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine instance.
ROUTINE_SCHEMA	FUNCSchema	VARCHAR(128)	Name of the SQL schema (schema) that contains the routine.
ROUTINE_NAME	FUNCNAME	VARCHAR(128)	Name of the routine.
ROUTINE_CREATED	RTNCREATE	TIMESTAMP	Identifies the timestamp when the routine was created.
ROUTINE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the routine.
ROUTINE_BODY	BODY	VARCHAR(8)	The type of the routine body: EXTERNAL This is an external routine. SQL This is an SQL routine.
EXTERNAL_NAME	EXTNAME	VARCHAR(279) Nullable	This column identifies the external program name. <ul style="list-style-type: none">• For SQL functions or ILE service programs, the external program name is <i>schema-name/service-program-name(entry-point-name)</i>.• For Java programs, the external program name is an optional jar-id followed by a <i>fully-qualified-class-name/method-name</i> or <i>fully-qualified-class-name.method-name</i>.• For all other languages, the external program name is <i>schema-name/program-name</i>. Contains the null value if this is a system-generated function.
EXTERNAL_LANGUAGE	LANGUAGE	VARCHAR(8) Nullable	If this is an external routine, this column identifies the external program's language. C The external program is written in C. C++ The external program is written in C++. CL The external program is written in CL. COBOL The external program is written in COBOL. COBOLLE The external program is written in ILE COBOL. JAVA The external program is written in JAVA. PLI The external program is written in PL/I. RPG The external program is written in RPG. RPGLE The external program is written in ILE RPG. Contains the null value if this is not an external routine.

Table 182. SYSFUNCS view (continued)

Column Name	System Column Name	Data Type	Description
PARAMETER_STYLE	PARM_STYLE	VARCHAR(7) Nullable	If this is an external routine, this column identifies the parameter style (calling convention).
			DB2SQL This is the DB2SQL calling convention.
			DB2GNRL This is the DB2GENERAL calling convention.
			GENERAL This is the GENERAL calling convention.
			JAVA This is the JAVA calling convention.
			NULLS This is the GENERAL WITH NULLS calling convention.
			SQL This is the SQL standard calling convention.
			Contains the null value if this is not an external routine.
IS_DETERMINISTIC	DETERMINE	VARCHAR(3)	This column identifies whether the routine is deterministic. That is, whether a call to the routine with the same arguments will always return the same result.
			NO The routine is not deterministic.
			YES The routine is global deterministic.
			STM The routine is statement deterministic.
SQL_DATA_ACCESS	DATAACCESS	VARCHAR(8) Nullable	This column identifies whether a routine contains SQL and whether it reads or modifies data.
			NONE The routine does not contain any SQL statements.
			CONTAINS The routine contains SQL statements.
			READS The routine possibly reads data from a table or view.
			MODIFIES The routine possibly modifies data in a table or view or issues SQL DDL statements.
SQL_PATH	SQL_PATH	VARCHAR(3483) Nullable	If this is an SQL routine, this column identifies the path.
			Contains the null value if this is an external routine.
PARM_SIGNATURE	SIGNATURE	VARCHAR(16000)	This column identifies the routine signature.
NUMBER_OF_RESULTS	NUMRESULTS	SMALLINT Nullable	Identifies the number of results.
IN_PARMS	IN_PARMS	SMALLINT	Identifies the number of input parameters. 0 indicates that there are no input parameters.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement.
			Contains the null value if there is no long comment.
ROUTINE_DEFINITION	ROUTINEDEF	DBCLOB(2M) CCSID 13488 Nullable	If this is an SQL routine, this column contains the SQL routine body.
			If this is an obfuscated routine, the text starts with the WRAPPED keyword and is followed by the encoded form of the statement text.
			Contains the null value if this is not an SQL routine.

Table 182. SYSFUNCS view (continued)

Column Name	System Column Name	Data Type	Description
FUNCTION_ORIGIN	ORIGIN	CHAR(1)	<p>Identifies the type of function. If this is a procedure, this column contains a blank.</p> <p>B This is a built-in function (defined by Db2 for i).</p> <p>E This is a user-defined function.</p> <p>U This is a user-defined function that is based on another function.</p> <p>S This is a system-generated function.</p>
FUNCTION_TYPE	TYPE	CHAR(1)	<p>Identifies the form of the function. If this is a procedure, this column contains a blank.</p> <p>S This is a scalar function.</p> <p>C This is a column function.</p> <p>T This is a table function.</p>
EXTERNAL_ACTION	EXT_ACTION	CHAR(1) Nullable	<p>Identifies the whether the invocation of the function has external effects.</p> <p>E This function has external side effects.</p> <p>N This function does not have any external side effects.</p>
IS_NULL_CALL	NULL_CALL	VARCHAR(3) Nullable	<p>Identifies whether the function needs to be called if an input parameter is the null value.</p> <p>NO This function need not be called if an input parameter is the null value. If this is a scalar function, the result of the function is implicitly null if any of the operands are null. If this is a table function, the result of the function is an empty table if any of the operands are the null value.</p> <p>YES This function must be called even if an input operand is null.</p>
SCRATCH_PAD	SCRATCHPAD	INTEGER Nullable	<p>Identifies whether the address of a static memory area (scratch pad) is passed to the function.</p> <p>0 The function does not have a scratch pad.</p> <p>integer Indicates the size of the scratch pad passed to the function.</p>
FINAL_CALL	FINAL_CALL	VARCHAR(3) Nullable	<p>Indicates whether a final call to the function should be made to allow the function to clean up its work areas (scratch pads).</p> <p>NO No final call is made.</p> <p>YES A final call to the function is made when the statement is complete.</p>
PARALLELIZABLE	PARALLEL	VARCHAR(3) Nullable	<p>Identifies whether the function can be run in parallel.</p> <p>NO The function must be synchronous.</p> <p>YES The function can be run in parallel.</p>

Table 182. SYSFUNCS view (continued)

Column Name	System Column Name	Data Type	Description
DBINFO	DBINFO	VARCHAR(3)	Identifies whether information about the database is passed to the function.
		Nullable	NO No database information is passed to the function.
			YES Information about the database is passed to the function.
SOURCE_SPECIFIC_SCHEMA	SRCSCHHEMA	VARCHAR(128) Nullable	If this is sourced function and the source is user-defined, this column contains the name of the source schema. If this is a sourced function and the source is built-in, this column contains 'QSYS2'. Contains the null value if this is not a sourced function.
SOURCE_SPECIFIC_NAME	SRCNAME	VARCHAR(128) Nullable	If this is sourced function and the source is user-defined, this column contains the specific name of the source function name. Contains the null value if this is not a sourced function.
IS_USER_DEFINED_CAST	CAST_FUNC	VARCHAR(3)	Identifies whether this function is a cast function created when a distinct type was created.
		Nullable	NO This function is not a cast function.
			YES This function is a cast function.
CARDINALITY	CARD	BIGINT	Specifies the cardinality for a table function.
		Nullable	Contains the null value if the function is not a table function or if cardinality was not specified.
FENCED	FENCED	VARCHAR(3)	Identifies whether the function is fenced.
		Nullable	NO The function is not fenced.
			YES The function is fenced.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
ROUNDING_MODE	DECFLTRND	CHAR(1)	If this is an SQL function, identifies the DECFLOAT rounding mode.
		Nullable	C ROUND_CEILING
			D ROUND_DOWN
			F ROUND_FLOOR
			G ROUND_HALF_DOWN
			E ROUND_HALF_EVEN
			H ROUND_HALF_UP
			U ROUND_UP
			Contains the null value if the function is not an SQL function.

Table 182. SYSFUNCS view (continued)

Column Name	System Column Name	Data Type	Description
INLINE	INLINE	VARCHAR(3)	Identifies whether the function can potentially be inlined.
		Nullable	NO The function cannot be inlined.
			YES The function can be inlined.
ROUTINE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Contains the label for a routine. Contains the null value if a label does not exist.
SECURE	SECURE	CHAR(1)	Indicates whether the function is considered secure for row access control and column access control.
		N	The function is not considered secure for row access control and column access control.
		Y	The function is considered secure for row access control and column access control.
PIPELINED	PIPELINED	VARCHAR(3)	Identifies whether the table function is pipelined.
		Nullable	NO The table function is not a pipelined table function.
			YES The table function is a pipelined function.
			Contains the null value if the routine is not a table function.

SYSHISTORYTABLES

The SYSHISTORYTABLES view contains one row for every history table, whether or not the history table is part of an established versioning relationship.

The following table describes the columns in the SYSHISTORYTABLES view:

Table 183. SYSHISTORYTABLES view

Column name	System Column Name	Data Type	Description
HISTORY_TABLE_SCHEMA	HSTDBNAME	VARCHAR(128)	Schema name of the history table.
HISTORY_TABLE_NAME	HSTTBNAME	VARCHAR(128)	Name of the history table.
VERSIONING_STATUS	VERSIONSTS	CHAR(1)	Status of versioning
		E	A versioning relationship between the system-period temporal table and the history table has been established. The system-period temporal table is storing previous versions of modified rows in this history table.
		D	A versioning relationship between this history table and the system-period temporal table has been defined but not established.
PERIOD_NAME	PERIODNAME	VARCHAR(128)	Name of the period.
TABLE_SCHEMA	DBNAME	VARCHAR(128) Nullable	Name of the SQL schema that contains the temporal table. Contains the null value if the system-period temporal table does not exist.

Table 183. SYSHISTORYTABLES view (continued)

Column name	System Column Name	Data Type	Description
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the temporal table.
		Nullable	Contains the null value if the system-period temporal table does not exist.
SYSTEM_HISTORY_SCHEMA	SYSHSTLIB	CHAR(10)	System schema name of the history table.
SYSTEM_HISTORY_TABLE_NAME	SYSHSTNAME	CHAR(10)	System name of the history table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name of the temporal table.
		Nullable	Contains the null value if the system-period temporal table does not exist.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the temporal table.
		Nullable	Contains the null value if the system-period temporal table does not exist.

SYSINDEXES

The SYSINDEXES view contains one row for every index in the SQL schema created using the SQL CREATE INDEX statement, including indexes on the SQL catalog.

The following table describes the columns in the SYSINDEXES view:

Table 184. SYSINDEXES view

Column Name	System Column Name	Data Type	Description
INDEX_NAME	NAME	VARCHAR(128)	Name of the index. This will be the SQL index name if one exists; otherwise, it will be the system index name.
INDEX_OWNER	CREATOR	VARCHAR(128)	Owner of the index
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table on which the index is defined. This will be the SQL table name if one exists; otherwise, it will be the system table name.
TABLE_OWNER	TBCREATOR	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	TBDBNAME	VARCHAR(128)	Name of the SQL schema that contains the table on which the index is defined
IS_UNIQUE	UNIQUERULE	CHAR(1)	If the index is unique: D No (duplicates are allowed) V Yes (duplicate NULL values are allowed) U Yes E Encoded vector index
COLUMN_COUNT	COLCOUNT	INTEGER	Number of columns in the key
INDEX_SCHEMA	DBNAME	VARCHAR(128)	Name of the SQL schema that contains the index
SYSTEM_INDEX_NAME	SYS_IXNAME	CHAR(10)	System index name
SYSTEM_INDEX_SCHEMA	SYS_IDNAME	CHAR(10)	System index schema name
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System table schema name
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200	A character string supplied with the COMMENT statement. Nullable Contains the null value if there is no long comment.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

Table 184. SYSINDEXES view (continued)

Column Name	System Column Name	Data Type	Description
INDEX_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200	A character string supplied with the LABEL statement.
IS_SPANNING_INDEX	SPANNING	VARCHAR(11) Nullable	Indicates whether the index is built over multiple partitions or members: DISTRIBUTED The index is built over a distributed table. NO The index is not built over multiple partitions or members. YES The index is built over multiple partitions or members. Contains the null value if the base table is not a partitioned table.
INDEX_DEFINER	DEFINER	VARCHAR(128) Nullable	Name of the user that defined the index.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	Indicates the DECFLOAT rounding mode of the index: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the index does not have an expression that references a DECFLOAT column, function, or constant.
INDEX_HAS_SEARCH_CONDITION	IXHASWHERE	CHAR(1)	If the index has a search condition: N The index does not have a search condition. Y The index has a search condition.
SEARCH_CONDITION_HAS_UDF	IXWHEREUDF	CHAR(1)	If the index search condition contains a user-defined function: N The index is not sparse or does not contain a user-defined function. Y The index is sparse and the search condition contains a UDF.
SEARCH_CONDITION	IXWHERECON	DBCLOB(2M) CCSID 1200 Nullable	If the index is sparse, contains the search condition. Contains the null value if the index is not sparse.
INDEX_HAS_INCLUDE_EXPRESSION	IXHASINCEX	CHAR(1)	If the index contains an INCLUDE clause: N The index does not contain an INCLUDE clause. Y The index contains an INCLUDE clause.

Table 184. SYSINDEXES view (continued)

Column Name	System Column Name	Data Type	Description
INCLUDE_EXPRESSION	IXINCEXPR	DBCLOB(2M) CCSID 1200 Nullable	If the index has an INCLUDE clause, contains the list of INCLUDE expressions. Contains the null value if there is no include clause.
CREATED	CREATED	TIMESTAMP	The timestamp when the SQL index was created.

SYSINDEXSTAT

The SYSINDEXSTAT view contains one row for every SQL index partition.

Use this view when you want to see information for a specific SQL index or set of SQL indexes. The information is similar to that returned via Show Indexes in System i Navigator.

The following table describes the columns in the SYSINDEXSTAT view:

Table 185. SYSINDEXSTAT view

Column name	System Column Name	Data Type	Description
INDEX_SCHEMA	INDSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the SQL index.
INDEX_NAME	INDNAME	VARCHAR(128)	Name of the SQL index.
INDEX_PARTITION	INDPART	VARCHAR(128)	Partition or member name of the SQL index.
INDEX_OWNER	INDOWNER	VARCHAR(128)	SQL index owner.
INDEX_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the SQL index. Contains null if text does not exist for the SQL index.
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
INDEX_VALID	VALID	VARCHAR(3)	An indication of whether the SQL index is invalid and needs to be rebuilt: NO The SQL index is invalid. YES The SQL index is valid.
INDEX_CREATE_TIMESTAMP	INDCREATED	TIMESTAMP	The timestamp when the SQL index was created.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	The timestamp when the SQL index partition was created.
LAST_BUILD_TIMESTAMP	LASTBUILD	TIMESTAMP Nullable	The timestamp when the SQL index was last rebuilt. Contains null if the SQL index has never been built.
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	The timestamp of the last time the SQL index was used in a query since the last time the usage statistics were reset. If the SQL index has never been used in a query since the last time the usage statistics were reset, contains null.
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	The timestamp of the last time the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. If the SQL index has never been used for statistics since the last time the usage statistics were reset, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	The number of times the SQL index was used in a query since the last time the usage statistics were reset. If the SQL index has never been used in a query since the last time the usage statistics were reset, contains 0.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	The number of times the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. If the SQL index has never been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the SQL index was used directly by an application for native record I/O or SQL operations. If the SQL index has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the SQL index was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the SQL index has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the SQL index. For more information see the Change Object Description (CHGOBJD) command. If the SQL index's last used timestamp has never been reset, contains null.
NUMBER_KEY_COLUMNS	INDKEYS	BIGINT	Number of columns that define the SQL index key.
COLUMN_NAMES	COLNAMES	VARCHAR(1024)	A comma separated list of column names that define the SQL index key. If the length of all the column names exceeds 1024, '...' is returned at the end of the column value.
NUMBER_KEYS	NUMRIDS	BIGINT	Number of keys in the SQL index. If the SQL index is invalid, -1 is returned.
INDEX_SIZE	SIZE	BIGINT	Size (in bytes) of the data space index used by the SQL index.
NUMBER_PAGES	PAGES	BIGINT Nullable	Number of pages in the SQL index. The page unit is the LOGICAL_PAGE_SIZE of the index. If the SQL index is invalid or is an encoded vector index, contains null.
LOGICAL_PAGE_SIZE	PAGE_SIZE	INTEGER Nullable	The logical page size of the index. If the index is an encoded vector index, contains null.
UNIQUE	UNIQUE	VARCHAR(21)	Indicates whether an SQL index is unique: UNIQUE The SQL index is a UNIQUE index. UNIQUE WHERE NOT NULL The SQL index is a UNIQUE WHERE NOT NULL index. FIFO The SQL index is a non-unique first-in-first-out (FIFO) index. LIFO The SQL index is a non-unique last-in-last-out (LIFO) index. FCFO The SQL index is a non-unique first-change-first-out (FCFO) index.
MAXIMUM_KEY_LENGTH	KEY_LENGTH	INTEGER Nullable	Maximum key length of an SQL index. If the SQL index is an encoded vector index, contains null.
UNIQUE_PARTIAL_KEY_VALUES	KEYCARDS	VARCHAR(96) Nullable	The unique partial key values for the SQL index. If the index is an encoded vector index, the first unique partial key value is the total number of unique values for the entire index key. The remaining unique partial key values returned are not applicable.
OVERFLOW_VALUES	OVERFLOW	INTEGER Nullable	The number of distinct key values that have overflowed the encoded vector index. If the SQL index is not an encoded vector index, contains null.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
EVI_CODE_SIZE	CODE_SIZE	INTEGER Nullable	The size of the byte code of the encoded vector index. If the SQL index is not an encoded vector index, contains null.
SPARSE	SPARSE	VARCHAR(3)	Indicates whether the SQL index contains keys for all the rows of its depended on table: NO The index contains keys for all the rows of its depended on table. YES The SQL index includes a WHERE clause and does not contain keys for all the rows of its depended on table.
DERIVED_KEY	DERIVED	VARCHAR(3)	Indicates whether the any key columns in the SQL index are expressions: NO No key columns of the SQL index are expressions. YES At least one key column is an expression.
PARTITIONED	PARTITION	VARCHAR(11)	Indicates whether the SQL index is partitioned or not partitioned: DISTRIBUTED The index is built over a distributed table. NO The SQL index is not partitioned (spans multiple partitions). YES The SQL index is not built over a partitioned table or built over a partitioned table and is partitioned (does not span multiple partitions). Contains the null value if the base table is not a partitioned table.
ACCPHT_TYPE	ACCPHTTYPE	VARCHAR(4)	Indicates the type of SQL index: 1 TB The SQL index is a maximum 1 terabyte (*MAX1TB) binary radix index. 4 GB The SQL index is a maximum 4 gigabyte (*MAX4GB) binary radix index. EVI The SQL index is an encoded vector index.
SORT_SEQUENCE	SRTSEQ	VARCHAR(12)	Indicates whether the SQL index uses a collating sequence: BY HEX VALUE The SQL index does not use a collating table. *LANGIDSHR The SQL index uses a shared weight collating sequence (SRTSEQ). *LANGIDUNQ The SQL index uses a unique weight collating sequence (SRTSEQ). ALTSEQ The SQL index uses an alternate collating sequence (ALTSEQ).
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	The language ID of the SQL index. Contains null if the collating sequence is hex.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10) Nullable	Schema name of the sort sequence to use. Contains null if there is no sort sequence schema name.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
SORT_SEQUENCE_NAME	SRTSEQNAM	CHAR(10) Nullable	Name of the sort sequence to use. Contains null if there is no sort sequence name.
ESTIMATED_BUILD_TIME	ESTBLDTIME	INTEGER	Estimated time (in seconds) required to rebuild the SQL index.
LAST_BUILD_TIME	LSTBLDTIME	INTEGER Nullable	Elapsed time (in seconds) the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_KEYS	LSTBLDKEYS	BIGINT Nullable	Number of keys the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_DEGREE	LSTBLDDEG	SMALLINT Nullable	Parallel degree the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_TYPE	LSTBLDTYPE	CHAR(1) Nullable	An indication of whether the last index build was a complete build or a build from the delayed maintenance keys: 0 The last rebuild of the index was from the delayed maintenance keys. 1 The last build or rebuild of the index was a complete build from the rows in the table. If the index has never been built, contains null.
LAST_INVALIDATION_TIMESTAMP	LSTINVAL	TIMESTAMP Nullable	An indication of when the index was last invalidated. If the index has never been invalidated, contains null.
LAST_INVALIDATION_REASON_CODE	LSTINVRC	SMALLINT Nullable	The reason code when the index was last invalidated. 1 User requested. LAST_INVALIDATION_REASON_TYPE contains additional information. 2 Create or build index 3 Load. LAST_INVALIDATION_REASON_TYPE contains additional information. 4 IPL 5 Runtime error. LAST_INVALIDATION_REASON_TYPE contains additional information. 6 Modify index 7 Journal failed to build the index 8 Marked index as fixable during runtime 9 Marked index as fixable during IPL 10 Change end of data If the index has never been invalidated, contains null.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
LAST_INVALIDATION_REASON_TYPE	LSTINVRT	SMALLINT Nullable	The reason type when the index was last invalidated. When LAST_INVALIDATION_REASON_CODE is 1, the following reason types can be returned: 257 Reorganize 258 Copy 259 ALTER TABLE or CHGPF 260 Converting new member 261 Change to *FRCRBDAP 262 Change to *UNIQUE 416 Change to *REBLD When LAST_INVALIDATION_REASON_CODE is 3, the following reason types can be returned: 769 Index was marked for invalidation but the system crashed before the invalidation occurred 770 Index was associated with the overlaid data space header during a load 773 Partial load 774 Delayed maintenance mismatch 775 Pad key mismatch 777 Logical page size mismatch 778 Index not restored. File might have been saved with ACCPTH(*NO) or index did not exist when file was saved. 779 Index not restored. File might have been saved with ACCPTH(*NO) or index did not exist when file was saved. When LAST_INVALIDATION_REASON_CODE is 5, the following reason type can be returned: 1281 Index out of sync with file (Retrieve) 1282 Index out of sync with file (Enforce Constraint) If the index has never been invalidated, contains null.
INDEX_HELD	HELD	VARCHAR(3)	An indication of whether a pending rebuild of the SQL index is currently held by the user: NO A rebuild of the SQL index is not pending or is not held. YES A pending rebuild of the SQL index is held.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
MAINTENANCE	MAINT	VARCHAR(11) Nullable	The maintenance of the SQL index: REBUILD The SQL index is not maintained and is rebuilt at open time. DELAYED The SQL index maintenance is delayed until the index is opened. DO NOT WAIT The SQL index is immediately maintained. If the SQL index is an encoded vector index, contains null.
DELAYED_MAINT_KEYS	DLYKEYS	INTEGER Nullable	Number of keys that need to be inserted into the binary tree of a delayed maintenance index. If the SQL index is not a delayed maintenance index, contains null.
RECOVERY	RECOVERY	VARCHAR(10) Nullable	The recovery attribute of the SQL index: DURING IPL The SQL index is recovered, if necessary, at IPL. AFTER IPL The SQL index is recovered, if necessary, after IPL. NEXT OPEN The SQL index is recovered, if necessary, on the next open. If the SQL index is an encoded vector index, contains null.
ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode of the index: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP Contains the null value if the index does not have an expression that references a DECFLOAT column, function, or constant.
DECFLT_WARNING	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether DECFLOAT warnings are returned: NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned. Contains the null value if the index does not have an expression that references a DECFLOAT column, function, or constant.
LOGICAL_READS	LGLREADS	BIGINT	Number of logical read operations for the SQL index since the last IPL.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the index since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the index since the last IPL.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
SEARCH_CONDITION	IXWHERECON	VARGRAPHIC(1024) CCSID 1200 Nullable	If an index is sparse, the search condition of the index. If the length of the search condition exceeds 1024, '...' is returned at the end of the column value. Contains null if the index is not sparse.
SEARCH_CONDITION_HAS_UDF	IXWHEREUDF	VARCHAR(3) Nullable	If an index is sparse, indicates whether the search condition of the index contains a user-defined function. Contains null if the index is not sparse. NO The index search condition does not contain a UDF. YES The index search condition contains a UDF.
KEEP_IN_MEMORY	KEEPINMEM	VARCHAR(3)	Indicates whether the index should be kept in memory: NO No memory preference. YES The index should be kept in memory, if possible.
MEDIA_PREFERENCE	MEDIAPREF	VARCHAR(3)	Indicates the media preference of the index: ANY No media preference. SSD The index should be allocated on Solid State Disk (SSD), if possible.
INCLUDE_EXPRESSION	IXINCEXPR	VARGRAPHIC(1024) CCSID 1200 Nullable	Index INCLUDE expression. Contains null if the index does not have an INCLUDE expression.
OWNING_INDEX_SCHEMA	OWNINDSCH	VARCHAR(128)	Name of the schema of the object that owns the index.
OWNING_INDEX_NAME	OWNINDNAME	VARCHAR(128)	Name of the object that owns the index.
OWNING_INDEX_TYPE	OWNINDTYPE	VARCHAR(11)	The type of the object that owns the index: INDEX The owner is an SQL index. LOGICAL The owner is part of a logical file. PHYSICAL The owner is a part of a keyed physical file. PRIMARY KEY The owner is a primary key constraint. UNIQUE The owner is a unique constraint. FOREIGN KEY The owner is a foreign key constraint.
OWNING_INDEX_OWNER	OWNINDOWN	VARCHAR(128)	The owner of the object that owns the index.
OWNING_SYSTEM_INDEX_SCHEMA	OWNSYS_IXD	CHAR(10) Nullable	System index schema name of the owner of the index. Contains null if the owner is a constraint.
OWNING_SYSTEM_INDEX_NAME	OWNSYS_Ixn	CHAR(10) Nullable	The system name of the owner of the index. Contains null if the owner is a constraint.
OWNING_INDEX_TEXT	OWNLABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the object that owns the index. Contains null if text does not exist for the object.
OWNING_INDEX_PARTITION	OWNINDMMBR	VARCHAR(128) Nullable	Partition or member name of the object that owns the index. Contains null if the owner is a constraint.
SYSTEM_INDEX_SCHEMA	SYS_IDXDNAM	CHAR(10)	System index schema name.

Table 185. SYSINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
SYSTEM_INDEX_NAME	SYS_IXNAME	CHAR(10)	System index name.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System table schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSJARCONTENTS

The SYSJARCONTENTS table contains one row for each class defined by a jarid in the SQL schema.

The following table describes the columns in the SYSJARCONTENTS table.

Table 186. SYSJARCONTENTS table

Column Name	System Column Name	Data Type	Description
JARSCHEMA	JARSCHEMA	VARCHAR(128)	Name of the schema containing the jar_id.
JAR_ID	JAR_ID	VARCHAR(128)	Name of the jar_id.
CLASS	CLASS	VARCHAR(128)	Name of the class.
CLASS_SOURCE	CLASSSRC	DBCLOB(10485760) CCSID 13488 Nullable	Reserved. Contains the null value.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

SYSJAROBJECTS

The SYSJAROBJECTS table contains one row for each jarid in the SQL schema.

The following table describes the columns in the SYSJAROBJECTS table.

Table 187. SYSJAROBJECTS table

Column Name	System Column Name	Data Type	Description
JARSCHEMA	JARSCHEMA	VARCHAR(128)	Name of the schema containing the jar_id.
JAR_ID	JAR_ID	VARCHAR(128)	Name of the jar_id.
DEFINER	DEFINER	VARCHAR(128)	Name of the owner of the jarid.
JAR_DATA	JAR_DATA	BLOB(104857600) Nullable	Byte-codes for the jar.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
JAR_CREATED	CREATEDTS	TIMESTAMP	Jar created timestamp.
LAST_ALTERED	ALTEREDTS	TIMESTAMP Nullable	Reserved. Contains the null value.

Table 187. SYSJAROBJECTS table (continued)

Column Name	System Column Name	Data Type	Description
DEBUG_MODE	DEBUG_MODE	CHAR(1)	Identifies whether the routine is debuggable. 0 The routine is not debuggable. 1 The routine is debuggable by the Unified Debugger. 2 The routine is debuggable by the system debugger. N The routine is disabled from being debugged by the Unified Debugger.
DEBUG_DATA	DEBUG_DATA	CLOB(1048576) Nullable	Reserved. Contains the null value.

SYSKEYCST

The SYSKEYCST view contains one or more rows for each UNIQUE KEY, PRIMARY KEY, or FOREIGN KEY in the SQL schema. There is one row for each column in every unique or primary key constraint and the referencing columns of a referential constraint.

The following table describes the columns in the SYSKEYCST view:

Table 188. SYSKEYCST view

Column Name	System Column Name	Data Type	Description
CONSTRAINT_SCHEMA	CDBNAME	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.
TABLE_SCHEMA	TDBNAME	VARCHAR(128)	Name of the schema containing the table.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table.
COLUMN_NAME	COLNAME	VARCHAR(128)	Name of the column.
ORDINAL_POSITION	COLSEQ	INTEGER	The position of the column within the key
COLUMN_POSITION	COLNO	INTEGER	The position of the column within the row
TABLE_OWNER	CREATOR	VARCHAR(128)	Owner of the table.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	System name of the column.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the schema table.
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.

SYSKEYS

The SYSKEYS view contains one row for every column of an index in the SQL schema, including the keys for the indexes on the SQL catalog.

The following table describes the columns in the SYSKEYS view:

Table 189. SYSKEYS view

Column Name	System Column Name	Data Type	Description
INDEX_NAME	IXNAME	VARCHAR(128)	Name of the index. This will be the SQL index name if one exists; otherwise, it will be the system index name.
INDEX_OWNER	IXCREATOR	VARCHAR(128)	Owner of the index

Table 189. SYSKEYS view (continued)

Column Name	System Column Name	Data Type	Description
COLUMN_NAME	COLNAME	VARCHAR(128)	Name of the column of the key. This will be the SQL column name if one exists; otherwise, it will be the system column name.
COLUMN_POSITION	COLNO	INTEGER Nullable	Numeric position of the column in the row. Contains the null value if the key column is an expression.
ORDINAL_POSITION	COLSEQ	INTEGER	Numeric position of the column in the key
ORDERING	ORDERING	CHAR(1)	Order of the column in the key: A Ascending D Descending
INDEX_SCHEMA	IXDBNAME	VARCHAR(128)	Name of the schema containing the index.
SYSTEM_COLUMN_NAME	SYS_CNAME	CHAR(10)	System name of the column
SYSTEM_INDEX_NAME	SYS_IXNAME	CHAR(10)	System name of the index
SYSTEM_INDEX_SCHEMA	SYS_IDNAME	CHAR(10)	System name of the schema containing the index
COLUMN_IS_EXPRESSION	IXISEXP	CHAR(1)	If the key column is an expression: Y The key column is not an expression. N The key column is an expression.
EXPRESSION_HAS_UDF	IXEXPUDF	CHAR(1) Nullable	If the key column is an expression and the expression contains a user-defined function: N The key column is not an expression or the expression does not contain a user-defined function. Y The key column is an expression and the expression contains a UDF.
KEY_EXPRESSION	IXKEYEXP	DBCLOB(2097152) CCSID 1200 Nullable	If the key column is an expression, contains the expression. Contains the column name if the key column is not an expression.

SYSMEMBERSTAT

The SYSMEMBERSTAT view contains one row for every file member, including members for program described files.

See [QSYS2.SYSMEMBERSTAT](#) for a description of the view.

SYSMQTSTAT

The SYSMQTSTAT view contains one row for every materialized table partition.

Use this view when you want to see information about a specified materialized query table or set of materialized query tables. The information is similar to that returned via Show Materialized Query Tables in System i Navigator.

The following table describes the columns in the SYSMQTSTAT view:

Table 190. SYSMQTSTAT view

Column name	System Column Name	Data Type	Description
MQT_SCHEMA	MQTSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the materialized query table.

Table 190. SYSMQTSTAT view (continued)

Column name	System Column Name	Data Type	Description
MQT_NAME	MQTNAME	VARCHAR(128)	Name of the materialized query table.
MQT_PARTITION	MQTMEMBER	VARCHAR(128)	Partition or member name of the materialized query table.
MQT_OWNER	MQTOWNER	VARCHAR(128)	Materialized query table owner.
MQT_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the materialized query table. Contains null if text does not exist for the materialized query table.
ENABLED	ENABLED	VARCHAR(3)	An indication of whether the materialized query table is enabled: NO The materialized query table is not enabled for use. YES The materialized query table is enabled for use by the database manager.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	The timestamp when the materialized query table was created.
REFRESH_TIME	REFRESHDTS	TIMESTAMP Nullable	The timestamp when the materialized query table was last refreshed. Contains null if the materialized query table has never been refreshed.
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains null.
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used by the optimizer for statistics since the last time the usage statistics were reset. If the materialized query table has never been used for statistics since the last time the usage statistics were reset, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	The number of times the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains 0.
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	The number of times the materialized query table was used by the optimizer for statistics since the last time the usage statistics were reset. If the materialized query table has never been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used directly by an application for native record I/O or SQL operations. If the materialized query table has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the materialized query table was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the materialized query table has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the materialized query table. For more information see the Change Object Description (CHGOBJD) command. If the materialized query table's last used timestamp has never been reset, contains null.
NUMBER_ROWS	CARD	BIGINT	Number of rows in the materialized query table.
MQT_SIZE	SIZE	BIGINT	Size (in bytes) of the materialized query table.

Table 190. SYSMQTSTAT view (continued)

Column name	System Column Name	Data Type	Description
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was changed. If the materialized query table has never been changed since the last time the usage statistics were reset, contains null.
MAINTENANCE	MAINTAIN	VARCHAR(6)	Indicates the maintenance for the materialized query table: SYSTEM The materialized query table is system maintained. USER The materialized query table is user maintained.
INITIAL_DATA	INITIAL	VARCHAR(19)	Indicates the initial data for the materialized query table: INITIALLY DEFERRED Data is not inserted into the materialized query table when it is created. INITIALLY IMMEDIATE Data is inserted into the materialized query table when it is created.
REFRESH	REFRESH	VARCHAR(9)	Indicates when the data in the materialized query table can be refreshed: DEFERRED Data in the materialized query table can be refreshed at any time using the REFRESH TABLE statement.
ISOLATION	ISOLATION	VARCHAR(27)	Indicates the isolation level used to refresh the materialized query table: NO COMMIT The isolation level is NO COMMIT. UNCOMMITTED READ The isolation level is UNCOMMITTED READ. CURSOR STABILITY The isolation level is CURSOR STABILITY. CURSOR STABILITY KEEP LOCKS The isolation level is CURSOR STABILITY KEEP LOCKS. READ STABILITY The isolation level is READ STABILITY. REPEATABLE READ The isolation level is REPEATABLE READ.
SORT_SEQUENCE	SRTSEQ	VARCHAR(12)	Indicates whether the materialize query table uses a collating sequence: BY HEX VALUE The materialize query table does not use a collating table. *LANGIDSHR The materialize query table uses a shared weight sort sequence (SRTSEQ). *LANGIDUNQ The materialize query table uses a unique weight sort sequence (SRTSEQ). ALTSEQ The materialize query table uses an alternate collating sequence (ALTSEQ).
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	The language ID of the materialize query table. Contains null if the sort sequence is hex.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10) Nullable	The sort sequence table system schema. Contains null if the sort sequence is hex.

Table 190. SYSMQTSTAT view (continued)

Column name	System Column Name	Data Type	Description
SORT_SEQUENCE_NAME	SRTSEQNAME	CHAR(10) Nullable	The sort sequence table name. Contains null if the sort sequence is hex.
MQT_RESTORE_DEFERRED	MQTRSTDFR	VARCHAR(3)	An indication of whether a restore of the MQT is pending the restore of one of its dependents: NO The restore of the MQT is not deferred pending the restore of one of its dependent tables. YES The restore of the MQT is deferred pending the restore of one of its dependent tables.
ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode of the materialized query table: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP Contains the null value if the materialized query table does not have an expression that references a DECFLOAT column, function, or constant.
DECFLOAT_WARNING	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether DECFLOAT warnings are returned: NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned. Contains the null value if the materialized query table does not have an expression that references a DECFLOAT column, function, or constant.
MQT_DEFINITION	MQTDEF	VARGRAPHIC(5000) CCSID 1200	The query of the materialized query table. If the length of the query exceeds 5000, '...' is returned at the end of the column value.
SYSTEM_MQT_SCHEMA	SYS_MQDNAM	CHAR(10)	System materialized query table schema name.
SYSTEM_MQT_NAME	SYS_MQNAME	CHAR(10)	System materialized query table name.

SYSPACKAGE

The SYSPACKAGE view contains one row for each SQL package in the SQL schema.

The following table describes the columns in the SYSPACKAGE view:

Table 191. SYSPACKAGE view

Column Name	System Column Name	Data Type	Description
PACKAGE_CATALOG	LOCATION	VARCHAR(128)	Relational database name (RDBNAME) of the SQL package
PACKAGE_SCHEMA	COLLID	VARCHAR(128)	Name of the schema
PACKAGE_NAME	NAME	VARCHAR(128)	Name of the SQL package
PACKAGE_OWNER	OWNER	VARCHAR(128)	Owner of the SQL package

Table 191. SYSPACKAGE view (continued)

Column Name	System Column Name	Data Type	Description
PACKAGE_CREATOR	CREATOR	VARCHAR(128)	Creator of the SQL package
CREATION_TIMESTAMP	TIMESTAMP	CHAR(26)	Timestamp of when the SQL package was created
DEFAULT_SCHEMA	QUALIFIER	VARCHAR(128)	Implicit name for unqualified tables, views, and indexes
PROGRAM_NAME	PROGNAME	VARCHAR(128)	Name of program the package was created from
PROGRAM_SCHEMA	LIBRARY	VARCHAR(128)	Name of schema containing the program
PROGRAM_CATALOG	RDB	VARCHAR(128)	Name of the relational database where the program resides
ISOLATION	ISOLATION	CHAR(2)	Isolation option specification. RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NO None (*NONE)
QUOTE	QUOTE	CHAR(1)	Escape character specification. Y Quotation mark N Apostrophe
COMMA	COMMA	CHAR(1)	Comma option specification. Y Comma N Period
PACKAGE_TEXT	LABEL	VARCHAR(50)	A character string you supply with the LABEL statement.
LONG_COMMENT	REMARKS	VARCHAR(2000)	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
CONSISTENCY_TOKEN	CONTOKEN	CHAR(8) FOR BIT DATA	Consistency token of package
SYSTEM_PACKAGE_NAME	SYS_NAME	CHAR(10)	System name of the package.
SYSTEM_PACKAGE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the package.
SYSTEM_DEFAULT_SCHEMA	SYS_DDNAME	CHAR(10)	System name of the implicit qualifier for unqualified table, views, indexes, and packages.
SYSTEM_PROGRAM_NAME	SYS_PNAME	CHAR(10)	System name of the program.
SYSTEM_PROGRAM_SCHEMA	SYS_PDNAME	CHAR(10)	System name of the schema containing the program
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

Table 191. SYSPACKAGE view (continued)

Column Name	System Column Name	Data Type	Description
ROUNDING_MODE	DECFLTRND	CHAR(1)	The rounding mode for the package: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP
CONCURRENTACCESSRESOLUTION	CONCURRENT	CHAR(1)	Specifies the concurrent access resolution: blank Not specified W Wait for outcome U Use currently committed

SYSPACKAGEAUTH

The SYSPACKAGEAUTH view contains one row for every privilege granted on a package. Note that this catalog view cannot be used to determine whether a user is authorized to a package because the privilege to use a package could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSPACKAGEAUTH view:

Table 192. SYSPACKAGEAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
PACKAGE_SCHEMA	COLLID	VARCHAR(128)	Name of the schema
PACKAGE_NAME	NAME	VARCHAR(128)	Name of the SQL package
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the package. EXECUTE The privilege to execute the package.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_PACKAGE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the package

Table 192. SYSPACKAGEAUTH view (continued)

Column Name	System Column Name	Data Type	Description
SYSTEM_PACKAGE_NAME	SYS_NAME	CHAR(10)	System name of the package

SYSPACKAGESTAT

The SYSPACKAGESTAT view contains one row for each SQL package in the SQL schema.

The following table describes the columns in the SYSPACKAGESTAT view:

Table 193. SYSPACKAGESTAT view

Column Name	System Column Name	Data Type	Description
PACKAGE_SCHEMA	COLLID	VARCHAR(128)	Name of the schema
PACKAGE_NAME	NAME	VARCHAR(128)	Name of the SQL package
PACKAGE_OWNER	OWNER	VARCHAR(128)	Owner of the SQL package
PACKAGE_CREATOR	CREATOR	VARCHAR(128)	Creator of the SQL package
CREATION_TIMESTAMP	TIMESTAMP	CHAR(26)	Timestamp of when the SQL package was created
DEFAULT_SCHEMA	QUALIFIER	VARCHAR(128)	Implicit name for unqualified tables, views, and indexes
ISOLATION	ISOLATION	CHAR(2)	Isolation option specification: RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NC No Commit (*NONE)
CONCURRENTACCESSRESOLUTION	CONCURRENT	CHAR(1)	Specifies the concurrent access resolution: blank Not specified W Wait for outcome U Use currently committed
SECONDARY_SPACE_COUNT	PKG_SPACES	INTEGER	Number of spaces in the package.
PENDING_FULL	PENDFULL	VARCHAR(3)	Indicates whether the package is pending full. NO The package is not pending full. YES The package is pending full. Contains null for a DRDA package.
ADHOC_PACKAGE	ADHOC	VARCHAR(3)	Indicates whether the package is created for single use only statements. NO The package includes statements that are prepared once and executed many times. YES The package includes statements that are prepared once and executed one time. Package compression will be activated before a second secondary space is added to the package. Contains null for a DRDA package.

Table 193. SYSPACKAGESTAT view (continued)

Column Name	System Column Name	Data Type	Description
PACKAGE_TYPE	PKG_TYPE	VARCHAR(16)	Indicates the type of package. EXTENDED_DYNAMIC The package is an extended dynamic package.
			DRDA The package is a DRDA package.
NUMBER_STATEMENTS	NBRSTMTS	INTEGER	Number of SQL statements in the package
PACKAGE_USED_SIZE	PKSIZE	INTEGER	Number of bytes that are used for SQL statements and access plans in the package
NUMBER_DUMMIES	NBRDUMMIES	INTEGER Nullable	Number of dummy statements in the package. Contains null for a DRDA package.
NUMBER_COMPRESSIONS	PGM_CMP	INTEGER Nullable	Number of times the package has been compressed. Contains null for a DRDA package.
STATEMENT_CONTENTION_COUNT	CONTENTION	BIGINT	Number of times contention occurred when attempting to store a new access plan.
EXTENDED_INDICATOR	EXTIND	VARCHAR(9)	Indicates the EXTIND attribute: *EXTIND Extended indicator support is enabled. *NOEXTIND Extended indicator support is not enabled.
C_NUL_REQUIRED	CNULRQD	VARCHAR(10)	Indicates the CNULRQD attribute: *CNULRQD C nuls are required. *NOCNULRQD C nuls are not required.
NAMING	NAMING	VARCHAR(4)	Indicates the NAMING attribute: *SYS This is system naming. *SQL This is SQL naming.
TARGET_RELEASE	TGTRLS	VARCHAR(6)	Indicates the target release of the package (VxRxMx).
EARLIEST_POSSIBLE_RELEASE	MINRLS	VARCHAR(6) Nullable	Indicates the earliest IBM i release that supports all the SQL statements in the package (VxRxMx). ANY The statements are valid on any supported IBM i release. VxRxMx The statement is valid on IBM i VxRxMx release or later. Contains null if the earliest release has not yet been determined.
RDB	RDB	VARCHAR(18)	Indicates the RDB specified for the package. rdb-name The name of the relational database. *NONE A relational database was not specified.
CONSISTENCY_TOKEN	CONTOKEN	VARBINARY(8) Nullable	Indicates the consistency token of the package. Contains null if the package is not a DRDA package.

Table 193. SYSPACKAGESTAT view (continued)

Column Name	System Column Name	Data Type	Description
ALLOW_COPY_DATA	ALWCPYDTA	VARCHAR(9)	<p>Indicates the ALWCPYDTA attribute:</p> <p>*NO A copy of the data is not allowed.</p> <p>*OPTIMIZE A copy of the data is allowed whenever it might result in better performance.</p> <p>*YES A copy of the data is allowed, but only when necessary.</p>
LOB_FETCH_OPTIMIZATION	OPTLOB	VARCHAR(9)	<p>Indicates the LOB optimization attribute:</p> <p>*OPTLOB The first FETCH for a cursor determines how the cursor will be used for LOB and XML result columns on all subsequent FETCHes.</p> <p>*NOOPTLOB Any FETCH may retrieve a LOB or XML result column into either a locator or variable.</p>
DECIMAL_POINT	DECPNT	VARCHAR(7)	<p>Indicates the decimal point for numeric constants used in SQL statements.</p> <p>*PERIOD The decimal point is a period.</p> <p>*COMMA The decimal point is a comma.</p>
SQL_STRING_DELIMITER	STRDLM	VARCHAR(9)	<p>Indicates the character used as the string delimiter in the SQL statements.</p> <p>*APOSTSQL The string delimiter is an apostrophe (').</p> <p>*QUOTESQL The string delimiter is a quote (").</p>
DATE_FORMAT	DATFMT	VARCHAR(4)	<p>Indicates the DATFMT attribute:</p> <p>*JOB The date format specified in the job at runtime is used.</p> <p>*USA The date format is *USA.</p> <p>*ISO The date format is *ISO.</p> <p>*EUR The date format is *EUR.</p> <p>*JIS The date format is *JIS.</p> <p>*MDY The date format is *MDY.</p> <p>*DMY The date format is *DMY.</p> <p>*YMD The date format is *YMD.</p> <p>*JUL The date format is *JUL.</p>
DATE_SEPARATOR	DATSEP	CHAR(1)	Indicates the date separator.

Table 193. SYSPACKAGESTAT view (continued)

Column Name	System Column Name	Data Type	Description
TIME_FORMAT	TIMFMT	VARCHAR(4)	<p>Indicates the TIMFMT attribute:</p> <p>*JOB The time format specified in the job at runtime is used.</p> <p>*USA The time format is *USA.</p> <p>*ISO The time format is *ISO.</p> <p>*EUR The time format is *EUR.</p> <p>*JIS The time format is *JIS.</p> <p>*HMS The date format is *HMS.</p>
TIME_SEPARATOR	TIMSEP	CHAR(1)	Indicates the time separator.
DYNAMIC_DEFAULT_SCHEMA	DYNDFTCOL	VARCHAR(4) Nullable	<p>Indicates whether the value for DFTRDBCOL should be used for implicit qualification on dynamic SQL statements:</p> <p>*NO The schema specified in DFTDRBCOL is not used for dynamic SQL statements.</p> <p>*YES The schema specified in DFTDRBCOL is used for dynamic SQL statements.</p> <p>Contains null if a default schema was not specified (DFTRDBCOL).</p>
CURRENT_RULES	SQLCURRULE	VARCHAR(4)	<p>Indicates the SQLCURRULE attribute:</p> <p>*DB2 The semantics of all SQL statements will default to the rules established for Db2.</p> <p>*STD The semantics of all SQL statements will default to the rules established by the ISO and ANSI SQL standards.</p>
ALLOW_BLOCK	ALWBLK	VARCHAR(8)	<p>Indicates the ALWBLK attribute:</p> <p>*ALLREAD Rows are blocked for read-only cursors.</p> <p>*NONE Rows are not blocked for retrieval of data for cursors.</p> <p>*READ Records are blocked for read-only retrieval of data for cursors when: <ul style="list-style-type: none"> • *NONE is specified for the Commitment control (COMMIT) parameter. • The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor. </p>
DELAY_PREPARE	DLYPRP	VARCHAR(4)	<p>Indicates the DLYPRP attribute:</p> <p>*NO Dynamic statement validation is performed when the dynamic statements are prepared.</p> <p>*YES Dynamic statement validation is delayed until the dynamic statements are used.</p>

Table 193. SYSPACKAGESTAT view (continued)

Column Name	System Column Name	Data Type	Description
USER_PROFILE	USRPRF	VARCHAR(7)	<p>Specifies the user profile used for authority checking:</p> <p>*USER The profile of the user running statements in the package is used.</p> <p>*OWNER The profiles of both the owner of the package and the user running statements in the package is used.</p> <p>*NAMING If the naming convention is *SQL, *OWNER is used. If the naming convention is *SYS, *USER is used.</p>
DYNAMIC_USER_PROFILE	DYNUSRPRF	VARCHAR(6)	<p>Specifies the user profile used for dynamic SQL statements:</p> <p>*USER Local dynamic SQL statements are run under the profile of the job or thread. Distributed dynamic SQL statements are run under the profile of the application server job.</p> <p>*OWNER Local dynamic SQL statements are run under the profile of the package's owner. Distributed dynamic SQL statements are run under the profile of the SQL package's owner.</p>
SORT_SEQUENCE	SRTSEQ	VARCHAR(12)	<p>Indicates whether the package uses a collating sequence:</p> <p>BY HEX VALUE The package does not use a collating table.</p> <p>*LANGIDSHR The package uses a shared weight sort sequence (SRTSEQ).</p> <p>*LANGIDUNQ The package uses a unique weight sort sequence (SRTSEQ).</p> <p>ALTSEQ The package uses an alternate collating sequence (ALTSEQ).</p>
LANGUAGE_IDENTIFIER	LANGID	CHAR(3)	The language ID sort sequence.
		Nullable	Contains null if the sort sequence is not *LANGIDSHR or *LANGIDUNQ.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10)	The sort sequence table system schema. Contains null if the sort sequence is hex.
		Nullable	
SORT_SEQUENCE_NAME	SRTSEQNAME	CHAR(10)	The sort sequence table name. Contains null if the sort sequence is hex.
		Nullable	
RDB_CONNECTION_METHOD	RDBCNNMTH	VARCHAR(4)	<p>Specifies the semantics used for CONNECT statements:</p> <p>*RUW CONNECT (Type 1) semantics are used to support remote unit of work.</p> <p>*DUW CONNECT (Type 2) semantics are used to support distributed unit of work.</p>
DECRESULT_MAXIMUM_PRECISION	DECMAXPRC	SMALLINT	Specifies the maximum precision.
			<p>31 The maximum precision is 31.</p> <p>63 The maximum precision is 63.</p>
DECRESULT_MAXIMUM_SCALE	DECMAXSCL	SMALLINT	The maximum scale (number of decimal positions to the right of the decimal point) that should be returned for result data types.

Table 193. SYSPACKAGESTAT view (continued)

Column Name	System Column Name	Data Type	Description
DECRESULT_MINIMUM_DIVIDE_SCALE	DECINDIV	SMALLINT	The minimum divide scale (number of decimal positions to the right of the decimal point) that should be returned for both intermediate and result data types.
DECFLOAT_ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP
DECFLOAT_WARNING	DECFLTWRN	VARCHAR(3)	Indicates whether DECFLOAT warnings are returned. NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned.
SQLPATH	SQLPATH	VARCHAR(3483) Nullable	Identifies the SQL path. Contains the null value if an SQL path is not specified.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the package was used. If the package has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the package was used since the last time the usage statistics were reset. If the package has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset. If the statistics have never been reset, contains null.
SYSTEM_PACKAGE_NAME	SYS_NAME	CHAR(10)	System name of the package.
SYSTEM_PACKAGE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the package.
IASP_NUMBER	IASPNUMBER	INTEGER	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
SYSTEM_TIME_SENSITIVE	SYSTIME	VARCHAR(3) Nullable	Specifies whether the CURRENT TEMPORAL SYSTEM_TIME special register affects static and dynamic SQL statements in the package. YES Any references to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. NO Any references to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. Contains null, which is treated like NO, if the package was created prior to 7.3.
NUMBER_COMPRESS_LOCK_CONFLICTS	NBRCMPLCK	INTEGER	The number of times a compress of the package space was not attempted because of a lock conflict.

SYSPACKAGESMTSTAT

The SYSPACKAGESMTSTAT view contains one row for each SQL statement in every SQL package.

The following table describes the columns in the SYSPACKAGESMTSTAT view:

Table 194. SYSPACKAGESMTSTAT view

Column Name	System Column Name	Data Type	Description
PACKAGE_SCHEMA	COLLID	VARCHAR(128)	Name of the schema.
PACKAGE_NAME	NAME	VARCHAR(128)	Name of the SQL package.
SPACE_NAME	SPCNAME	VARCHAR(10) Nullable	Generated space name within the package for extended dynamic packages. Contains the null value for DRDA packages which have only 1 internal space.
STATEMENT_NUMBER	STMTNBR	INTEGER	Number of this statement in the space.
STATEMENT_NAME	STMTNAME	VARCHAR(128) Nullable	Name of the statement. Contains the null value for DRDA packages.
NUMBER_TIMES_PREPARED	NBRPREP	INTEGER	Number of times this statement has been prepared.
NUMBER_TIMES_EXECUTED	NBREXEC	INTEGER	Number of times this statement has been executed. This value is not maintained for CALL, SET, or VALUES INTO statements.
ROWS_AFFECTED	ROWCNT	INTEGER	Total rows fetched, updated, inserted, or deleted for all executions of the statement. Contains 0 if the statement is not a FETCH, SET, VALUES INTO, UPDATE, INSERT, DELETE, or MERGE. Will contain 0 for a SET or VALUES INTO statement that is not implemented using a cursor.
COMPRESSES_SINCE_LAST_USED	CMPLU	INTEGER	Number of times the package has had storage compressed since this statement was last run. This value is used when processing the SQL_STMT_COMPRESS_MAX QAQQINI option to determine when to remove the space used for the QDT for a statement. Will always be 0 for DRDA packages.
PARAMETER_MARKER_CONVERTED	PMCNVT	CHAR(3)	For a dynamic statement, indicates whether literals were converted to parameter markers for statement reuse. YES Literals were converted to parameter markers. NO No conversion done or statement is not dynamic.
WITH_HOLD	WITHHOLD	CHAR(3) Nullable	Specifies the WITH HOLD option for statement: YES WITH HOLD clause specified. Contains the null value if the clause was not specified.
FETCH_ONLY	FETCHONLY	CHAR(3) Nullable	Specifies the FOR READ ONLY option for statement: YES FOR READ ONLY clause specified. Contains the null value if the clause was not specified.
CONCURRENTACCESSRESOLUTION	CONCURRENT	CHAR(1) Nullable	Specifies the concurrent access resolution for the statement: W Wait for outcome U Use currently committed S Skip locked data Contains the null value if concurrent access was not specified at the statement level.
NUMBER_REBUILDS	NBRREBLD	INTEGER	Number of times QDT or access plan has been rebuilt.

Table 194. SYSPACKAGESMTSTAT view (continued)

Column Name	System Column Name	Data Type	Description
ISOLATION	ISOLATION	CHAR(2) Nullable	Isolation option specification: RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NC No Commit (*NONE) Contains the null value if isolation level was not specified at the statement level.
NUMBER_ROWS_TO_OPTIMIZE	OPTROWS	INTEGER Nullable	Number of rows specified on the OPTIMIZE FOR <i>n</i> ROWS clause. -1 means that the value *ALL was specified. Contains the null value if the clause was not specified.
NUMBER_ROWS_TO_FETCH	FETCHROWS	INTEGER Nullable	Number of rows specified on FETCH FIRST <i>n</i> ROWS clause. Contains the null value if the clause was not specified.
LAST_QDT_REBUILD_REASON	QDTRBLD	CHAR(2) Nullable	Reason code for last QDT rebuild. This corresponds to column QVC22 in the STRDBMON outfile when QRID = 1000. Contains the null value if the statement does not use a QDT or has never had a QDT rebuilt.
STATEMENT_TEXT	STMTTEXT	DBCLOB(2M) CCSID(1200)	Text of the SQL statement.
SYSTEM_PACKAGE_NAME	SYS_NAME	CHAR(10)	System name of the package.
SYSTEM_PACKAGE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the package.
ACCESS_PLAN_LENGTH	AP_LENGTH	INTEGER	Number of bytes that are used for the QDT and access plan for the statement.

SYSPARMS

The SYSPARMS table contains one row for each parameter of a procedure created by the CREATE PROCEDURE statement or function created by the CREATE FUNCTION statement. The result of a scalar function and the result columns of a table function are also returned.

The following table describes the columns in the SYSPARMS table:

Table 195. SYSPARMS table

Column Name	System Column Name	Data Type	Description
SPECIFIC_SCHEMA	SPECSchema	VARCHAR(128)	Schema name of the routine instance.
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine instance.
ORDINAL_POSITION	PARMNO	INTEGER	Numeric place of the parameter in the parameter list, ordered from left to right from 1 (leftmost parameter) to <i>n</i> (<i>n</i> th parameter). For scalar functions, the result of the function has a value of <i>n</i> +1. For table functions, the result columns are numbered from <i>n</i> +1 (leftmost result column) to <i>n</i> + <i>m</i> (<i>m</i> th result column).

Table 195. SYSPARMS table (continued)

Column Name	System Column Name	Data Type	Description
PARAMETER_MODE	PARMMODE	VARCHAR(5)	Type of the parameter: IN This is an input parameter. OUT This is an output parameter. INOUT This is an input/output parameter.
PARAMETER_NAME	PARMNAME	VARCHAR(128) Nullable	Name of the parameter. Contains the null value if the parameter does not have a name.
DATA_TYPE	DATA_TYPE	VARCHAR(128)	Type of parameter: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Floating point; DOUBLE PRECISION REAL Floating point; REAL DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML DISTINCT Distinct type ARRAY Array type

Table 195. SYSPARMS table (continued)

Column Name	System Column Name	Data Type	Description
NUMERIC_SCALE	SCALE	INTEGER	Scale of numeric data.
		Nullable	Contains the null value if the parameter is not decimal, numeric, or binary.
NUMERIC_PRECISION	PRECISION	INTEGER	The precision of all numeric parameters.
		Nullable	<p>Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.</p> <p>Contains the null value if the parameter is not numeric.</p>
CCSID	CCSID	INTEGER	The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, and DATALINK parameters.
		Nullable	A CCSID of 0 indicates that the CCSID of the job at run time is used.
			XML parameters use the value of SQL_XML_DATA_CCSID from the QAQQINI file.
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER	Maximum length of the string for binary, character, and graphic string and XML data types.
		Nullable	Contains the null value if the parameter is not a string.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER	Number of bytes for binary, character, and graphic string and XML data types.
		Nullable	Contains the null value if the parameter is not a string.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits:
		Nullable	<p>2 Binary; floating-point precision is specified in binary digits.</p>
			<p>10 Decimal; all other numeric types are specified in decimal digits.</p>
			Contains the null value if the parameter is not numeric.
DATETIME_PRECISION	DATPRC	INTEGER	The fractional part of a date, time, or timestamp.
		Nullable	<p>0 For DATE and TIME data types</p>
			<p>0-12 For TIMESTAMP data types (number of fractional seconds).</p>
IS_NULLABLE	NULLS	VARCHAR(3)	Contains the null value if the parameter is not date, time, or timestamp.
			Indicates whether the parameter is nullable.
			<p>NO The parameter does not allow nulls.</p>
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200	A character string supplied with the COMMENT statement.
		Nullable	Contains the null value if there is no long comment.

Table 195. SYSPARMS table (continued)

Column Name	System Column Name	Data Type	Description
ROW_TYPE	ROWTYPE	CHAR(1) Nullable	Indicates the type of row. P Parameter. R If the function is a table function, this indicates a result column. Otherwise, the result before casting. C Result after casting.
DATA_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128) Nullable	Schema of the data type if this is a distinct type. Contains the null value if the parameter is not a distinct type.
DATA_TYPE_NAME	TYPENAME	VARCHAR(128) Nullable	Name of the data type if this is a distinct type. Contains the null value if the parameter is not a distinct type.
AS_LOCATOR	ASLOCATOR	VARCHAR(3)	Indicates whether the parameter was specified as a locator. NO The parameter was not specified as a locator. YES The parameter was specified as a locator.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
NORMALIZE_DATA	NORMALIZE	VARCHAR(3) Nullable	Indicates whether the parameter value should be normalized or not. This attribute only applies to UTF-8 and UTF-16 data. NO The value should not be normalized. YES The value should be normalized.
DEFAULT	DEFAULT	DBCLOB(64K) CCSID 1200 Nullable	The expression string used to calculate the default value of a parameter, if one exists. If the default value is the null value, the expression string is the keyword NULL. Contains the null value if the parameter has no default.

SYSPARTITIONDISK

The SYSPARTITIONDISK view contains one row for every disk unit used to store data of every table partition or table member. If the table is a distributed table, the partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSPARTITIONDISK view:

Table 196. SYSPARTITIONDISK view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
ASP_NUMBER	ASP_NUMBER	SMALLINT	Auxiliary Storage Pool (ASP) containing the partition. 1 indicates the system ASP.
DISK_TYPE	DISK_TYPE	VARCHAR(4)	Disk type number of the disk.
DISK_MODEL	DISK_MODEL	VARCHAR(4)	Model number of the disk.
UNIT_NUMBER	UNITNBR	SMALLINT	Unit number of the disk.

Table 196. SYSPARTITIONDISK view (continued)

Column name	System Column Name	Data Type	Description
LOGICAL_MIRRORED_PAIR_STATUS	MIRRORPS	CHAR(1) Nullable	Indicates the status of a mirrored pair of disks: 0 Indicates that one mirrored unit of a mirrored pair is not active. 1 Indicates that both mirrored units of a mirrored pair are active. Contains null if the unit is not mirrored.
MIRRORED_UNIT_STATUS	MIRRORUS	CHAR(1) Nullable	Indicates the status of a mirrored unit: 1 Indicates that this mirrored unit of a mirrored pair is active (online with current data). 2 Indicates that this mirrored unit is being synchronized. 3 Indicates that this mirrored unit is suspended. Contains null if the unit is not mirrored.
UNIT_MEDIA_CAPACITY	UNITMCAP	BIGINT	Storage capacity (in bytes) of the unit.
UNIT_SPACE_AVAILABLE	UNITSPACE	BIGINT	Space (in bytes) available on the unit for use.
UNIT_SPACE_RESERVED_FOR_SYSTEM	UNITSRES	BIGINT	Space (in bytes) reserved on the unit for use by the system.
UNIT_SPACE_USED	UNITSUSED	BIGINT	Space (in bytes) on the unit used for the partition.
UNIT_TOTAL_ACCESS_TIME	UNITTATIME	INTEGER	The estimated time, in milliseconds, required to sequentially read the fixed-length data on the unit for the partition. The time is based on the amount of data on the unit and the average access time of the unit. The estimate assumes there will be no contention with other threads for the disk.
UNIT_TYPE	UNIT_TYPE	SMALLINT	Indicates the type of disk unit: 0 Not Solid State Disk (SSD). 1 Solid State Disk (SSD).
DATA_SEGMENT_TYPE	SEGMENT	SMALLINT	Segment type of the disk: 0 Indicates that this segment is for fixed-length data. 1 Indicates that this segment is for variable-length data.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPARTITIONINDEXDISK

The SYSPARTITIONINDEXDISK view contains one row for every disk unit used to store the index data of every table partition or table member. If the index is a distributed index, the partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSPARTITIONINDEXDISK view:

Table 197. SYSPARTITIONINDEXDISK view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
PARTITION_NUMBER	PARTNBR	INTEGER Nullable	The partition number of this partition. If the table is a distributed table, contains null.
NUMBER_DISTRIBUTED_PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
INDEX_SCHEMA	INDSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the index, logical file, or constraint.
INDEX_NAME	INDNAME	VARCHAR(128)	Name of the index, logical file, or constraint.
INDEX_MEMBER	INDMEMBER	VARCHAR(128) Nullable	Name of the member of the index or logical file. If the index type is a constraint, the member name is null.
INDEX_TYPE	INDTYPE	VARCHAR(11)	The type of the index: INDEX The index is an SQL index. LOGICAL The index is part of a logical file. PHYSICAL The index is part of a keyed physical file. PRIMARY KEY The index is a primary key constraint. UNIQUE The index is a unique constraint. REFERENTIAL The index is a foreign key constraint.
PARTITIONED	PARTITION	CHAR(1)	Indicates whether the index is partitioned or not partitioned: 0 An SQL index is not partitioned (spans multiple partitions). 1 The index is not built over a partitioned table or built over a partitioned table and is partitioned (does not span multiple partitions or members). 2 The index is a logical file built over multiple partitions or members.
ASP_NUMBER	ASP_NUMBER	SMALLINT	Auxiliary Storage Pool (ASP) containing the index. 1 indicates the system ASP.
DISK_TYPE	DISK_TYPE	VARCHAR(4)	Disk type number of the disk.
DISK_MODEL	DISK_MODEL	VARCHAR(4)	Model number of the disk.
UNIT_NUMBER	UNITNBR	SMALLINT	Unit number of the disk.

Table 197. SYSPARTITIONINDEXDISK view (continued)

Column name	System Column Name	Data Type	Description
LOGICAL_MIRRORED_PAIR_STATUS	MIRRORPS	CHAR(1) Nullable	Indicates the status of a mirrored pair of disks: 0 Indicates that one mirrored unit of a mirrored pair is not active. 1 Indicates that both mirrored units of a mirrored pair are active. Contains null if the unit is not mirrored.
MIRRORED_UNIT_STATUS	MIRRORUS	CHAR(1) Nullable	Indicates the status of a mirrored unit: 1 Indicates that this mirrored unit of a mirrored pair is active (online with current data). 2 Indicates that this mirrored unit is being synchronized. 3 Indicates that this mirrored unit is suspended. Contains null if the unit is not mirrored.
UNIT_MEDIA_CAPACITY	UNITMCAP	BIGINT	Storage capacity (in bytes) of the unit.
UNIT_SPACE_AVAILABLE	UNITSPACE	BIGINT	Space (in bytes) available on the unit for use.
UNIT_SPACE_RESERVED_FOR_SYSTEM	UNITSRES	BIGINT	Space (in bytes) reserved on the unit for use by the system.
UNIT_SPACE_USED	UNITSUSED	BIGINT	Space (in bytes) on the unit used for the index.
UNIT_TYPE	UNIT_TYPE	SMALLINT	Indicates the type of disk unit: 0 Not Solid State Disk (SSD). 1 Solid State Disk (SSD).
SYSTEM_INDEX_SCHEMA	SYS_IXDNAME	CHAR(10)	System index schema name.
SYSTEM_INDEX_NAME	SYS_IXNAME	CHAR(10)	System index name.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPARTITIONINDEXES

The SYSPARTITIONINDEXES view contains one row for every index built over a table partition or table member. Indexes that share another index's binary tree are not included. If the table is a distributed table, the indexes over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

Use this view when you want to see index information for indexes built on a specified table or set of tables. The information is similar to that returned via Show Indexes in System i Navigator

The following table describes the columns in the SYSPARTITIONINDEXES view:

Table 198. SYSPARTITIONINDEXES view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
INDEX_NAME	INDNAME	VARCHAR(128)	Name of the index, logical file, or constraint. If the index type indicates one or more temporary indexes, INDEX_NAME contains the number of maintained temporary indexes that currently exist on the table followed by the string 'MAINTAINED TEMPORARY INDEXES'.
INDEX_TYPE	INDTYPE	VARCHAR(11)	The type of the index: INDEX The index is an SQL index. LOGICAL The index is part of a logical file. PHYSICAL The index is a part of a keyed physical file. PRIMARY KEY The index is a primary key constraint. UNIQUE The index is a unique constraint. FOREIGN KEY The index is a foreign key constraint. TEMPORARY Indicates one or more temporary indexes exist on the table.
INDEX_SCHEMA	INDSCHEMA	VARCHAR(128) Nullable	Name of the SQL schema that contains the index, logical file, or constraint. Contains null if the row indicates one or more maintained temporary indexes.
INDEX_OWNER	INDOWNER	VARCHAR(128) Nullable	Index owner. Contains null if the row indicates one or more maintained temporary indexes.
SYSTEM_INDEX_SCHEMA	SYS_IXDNAME	CHAR(10) Nullable	System index schema name. Contains null unless the index type is INDEX or LOGICAL.
SYSTEM_INDEX_NAME	SYS_IXNAME	CHAR(10) Nullable	System index name. Contains null unless the index type is INDEX or LOGICAL.
INDEX_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the index, logical file, or constraint. Contains null if text does not exist for the index.
INDEX_PARTITION	INDMEMBER	VARCHAR(128) Nullable	Partition or member name of the index. Contains null if the row indicates one or more maintained temporary indexes.
INDEX_VALID	VALID	VARCHAR(3)	An indication of whether the index is invalid and needs to be rebuilt: NO The index is invalid. YES The index is valid.
CREATE_TIMESTAMP	CREATED	TIMESTAMP Nullable	The timestamp when the index was created. Contains null if the row indicates one or more maintained temporary indexes.
LAST_BUILD_TIMESTAMP	LASTBUILD	TIMESTAMP Nullable	The timestamp when the index was last rebuilt. Contains null if the row indicates one or more maintained temporary indexes.
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	The timestamp of the last time the index was used in a query since the last time the usage statistics were reset. If the index has never been used in a query since the last time the usage statistics were reset or if the row indicates one or more maintained temporary indexes, contains null.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	The timestamp of the last time the index was used by the optimizer for statistics since the last time the usage statistics were reset. If the index has never been used for statistics since the last time the usage statistics were reset or if the row indicates one or more maintained temporary indexes, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	The number of times the index was used in a query since the last time the usage statistics were reset. If the index has never been used in a query since the last time the usage statistics were reset, contains 0.
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	The number of times the index was used by the optimizer for statistics since the last time the usage statistics were reset. If the index has never been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP		TIMESTAMP Nullable	The timestamp of the last time the index was used directly by an application for native record I/O or SQL operations. If the index has never been used or if the row indicates one or more maintained temporary indexes, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the index was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the index has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the index. For more information see the Change Object Description (CHGOBJD) command. If the index's last used timestamp has never been reset, contains null.
NUMBER_KEY_COLUMNS	INDKEYS	BIGINT Nullable	Number of columns that define the index key. Contains null if the row indicates one or more maintained temporary indexes.
COLUMN_NAMES	COLNAMES	VARCHAR(1024) Nullable	A comma separated list of column names that define the index key. If the length of all the column names exceeds 1024, '...' is returned at the end of the column value. Contains null if the row indicates one or more maintained temporary indexes.
NUMBER_KEYS	NUMRIDS	BIGINT Nullable	Number of keys in the index. If the index is invalid or is an encoded vector index, -1 is returned. Contains null if the row indicates one or more maintained temporary indexes.
INDEX_SIZE	SIZE	BIGINT	Size (in bytes) of the data space index used by the index.
NUMBER_PAGES	PAGES	BIGINT Nullable	Number of pages in the index. The page unit is the LOGICAL_PAGE_SIZE of the index. If the index is invalid or is an encoded vector index, contains null.
LOGICAL_PAGE_SIZE	PAGE_SIZE	INTEGER Nullable	The logical page size of the index. If the index is an encoded vector index or if the row indicates one or more maintained temporary indexes, contains null.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
UNIQUE	UNIQUE	VARCHAR(21) Nullable	Indicates whether an index is unique: UNIQUE The index is a UNIQUE index. UNIQUE WHERE NOT NULL The index is a UNIQUE WHERE NOT NULL index. FIFO The index is a non-unique first-in-first-out (FIFO) index. LIFO The index is a non-unique last-in-last-out (LIFO) index. FCFO The index is a non-unique first-change-first-out (FCFO) index. Contains null if the row indicates one or more maintained temporary indexes.
MAXIMUM_KEY_LENGTH	KEY_LENGTH	INTEGER Nullable	Maximum key length of an index. If the index is an encoded vector index, contains null.
UNIQUE_PARTIAL_KEY_VALUES	KEYCARDS	VARCHAR(96) Nullable	The unique partial key values for the index. If the index is an encoded vector index, the first unique partial key value is the total number of unique values for the entire index key. The remaining unique partial key values returned are not applicable. If the index is one or more maintained temporary indexes, contains null.
OVERFLOW_VALUES	OVERFLOW	INTEGER Nullable	The number of distinct key values that have overflowed the encoded vector index. If the index is not an encoded vector index, contains null.
EVI_CODE_SIZE	CODE_SIZE	INTEGER Nullable	The size of the byte code of the encoded vector index. If the index is not an encoded vector index, contains null.
SPARSE	SPARSE	VARCHAR(3) Nullable	Indicates whether the index contains keys for all the rows of its depended on table: NO The index contains keys for all the rows of its depended on table. YES The index is a select/omit logical file or an SQL index with a WHERE clause and does not contain keys for all the rows of its depended on table. Contains null if the row indicates one or more maintained temporary indexes.
DERIVED_KEY	DERIVED	VARCHAR(3) Nullable	Indicates whether any key columns in the index are expressions: NO No key columns of the index are expressions. YES At least one key column is an expression. Contains null if the row indicates one or more maintained temporary indexes.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
PARTITIONED	PARTITION	VARCHAR(20) Nullable	Indicates whether the index is partitioned or not partitioned: NO An SQL index is not partitioned (spans multiple partitions). YES The index is not built over a partitioned table or built over a partitioned table and is partitioned (does not span multiple partitions or members). MULTI-MEMBER LOGICAL The index is a logical file built over multiple partitions or members. Contains null if the row indicates one or more maintained temporary indexes.
ACCPHT_TYPE	ACCPHTTYPE	VARCHAR(4) Nullable	Indicates the type of index: 1 TB The index is a maximum 1 terabyte (*MAX1TB) binary radix index. 4 GB The index is a maximum 4 gigabyte (*MAX4GB) binary radix index. EVI The index is an encoded vector index. Contains null if the row indicates one or more maintained temporary indexes.
SORT_SEQUENCE	SRTSEQ	VARCHAR(12) Nullable	Indicates whether the index uses a collating sequence: BY HEX VALUE The index does not use a collating table. *LANGIDSHR The index uses a shared weight sort sequence (SRTSEQ). *LANGIDUNQ The index uses a unique weight sort sequence (SRTSEQ). ALTSEQ The index uses an alternate collating sequence (ALTSEQ). Contains null if the row indicates one or more maintained temporary indexes.
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	The language ID of the index. Contains null if the sort sequence is hex or if the row indicates one or more maintained temporary indexes.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10) Nullable	Schema name of the sort sequence to use. Contains null if there is no schema name.
SORT_SEQUENCE_NAME	SRTSEQNAME	CHAR(10) Nullable	Name of the sort sequence to use. Contains null if there is no sort sequence name.
ESTIMATED_BUILD_TIME	ESTBLDTIME	INTEGER Nullable	Estimated time (in seconds) required to rebuild the index. Contains null if the row indicates one or more maintained temporary indexes.
LAST_BUILD_TIME	LSTBLDTIME	INTEGER Nullable	Elapsed time (in seconds) the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_KEYS	LSTBLDKEYS	BIGINT Nullable	Number of keys the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_DEGREE	LSTBLDDEG	SMALLINT Nullable	Parallel degree the last time the index was built. Contains null if the last build information is not available.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
LAST_BUILD_TYPE	LSTBLDTYPE	CHAR(1) Nullable	An indication of whether the last index build was a complete build or a build from the delayed maintenance keys: 0 The last rebuild of the index was from the delayed maintenance keys. 1 The last build or rebuild of the index was a complete build from the rows in the table. If the index has never been built, contains null.
LAST_INVALIDATION_TIMESTAMP	LSTINVAL	TIMESTAMP Nullable	An indication of when the index was last invalidated. If the index has never been invalidated, contains null.
LAST_INVALIDATION_REASON_CODE	LSTINVRC	SMALLINT Nullable	The reason code when the index was last invalidated. Reason code values are listed in the SYSINDEXSTAT view. If the index has never been invalidated, contains null.
LAST_INVALIDATION_REASON_TYPE	LSTINVRT	SMALLINT Nullable	The reason type when the index was last invalidated. Reason type values are listed in the SYSINDEXSTAT view. If the index has never been invalidated, contains null.
INDEX_HELD	HELD	VARCHAR(3)	An indication or whether a pending rebuild of the index is currently held by the user: NO A rebuild of the index is not pending or is not held. YES A pending rebuild of the index is held.
MAINTENANCE	MAINT	VARCHAR(11) Nullable	The maintenance of the index: REBUILD The index is not maintained and is rebuilt at open time. DELAYED The index maintenance is delayed until the index is opened. DO NOT WAIT The index is immediately maintained. If the index is an encoded vector index or if the row indicates one or more maintained temporary indexes, contains null.
DELAYED_MAINT_KEYS	DLYKEYS	INTEGER Nullable	Number of keys that need to be inserted into the binary tree of a delayed maintenance index. If the index is not a delayed maintenance index, contains null.
RECOVERY	RECOVERY	VARCHAR(10) Nullable	The recovery attribute of the index: DURING IPL The index is recovered, if necessary, at IPL. AFTER IPL The index is recovered, if necessary, after IPL. NEXT OPEN The index is recovered, if necessary, on the next open. If the index is an encoded vector index or if the row indicates one or more maintained temporary indexes, contains null.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode of the index: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP
			Contains the null value if the index does not have an expression that references a DECFLOAT column, function, or constant; or if the row indicates one or more maintained temporary indexes.
DECFLOAT_WARNING	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether DECFLOAT warnings are returned: NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned.
			Contains the null value if the index does not have an expression that references a DECFLOAT column, function, or constant; or if the row indicates one or more maintained temporary indexes.
LOGICAL_READS	LGLREADS	BIGINT Nullable	Number of logical read operations for the index since the last IPL. Contains null if the row indicates one or more maintained temporary indexes.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the index since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the index since the last IPL.
SEARCH_CONDITION	IXWHERECON	VARGRAPHIC(1024) CCSID 1200 Nullable	If an index is sparse, the search condition of the index. If the length of the search condition exceeds 1024, '...' is returned at the end of the column value. Contains null if the index is not sparse.
SEARCH_CONDITION_HAS_UDF	IXWHEREUDF	VARCHAR(3) Nullable	If an index is sparse, indicates whether the search condition of the index contains a user-defined function. Contains null if the index is not sparse. NO The index search condition does not contain a UDF. YES The index search condition contains a UDF.
KEEP_IN_MEMORY	KEEPINMEM	VARCHAR(3)	Indicates whether the index should be kept in memory: NO No memory preference. YES The index should be kept in memory, if possible.
MEDIA_PREFERENCE	MEDIAPREF	VARCHAR(3)	Indicates the media preference of the index: ANY No media preference. SSD The index should be allocated on Solid State Disk (SSD), if possible.

Table 198. SYSPARTITIONINDEXES view (continued)

Column name	System Column Name	Data Type	Description
INCLUDE_EXPRESSION	IXINCEXPR	VARGRAPHIC(1024) CCSID 1200 Nullable	Index INCLUDE expression. Contains null if the index does not have an INCLUDE expression.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPARTITIONINDEXSTAT

The SYSPARTITIONINDEXSTAT view contains one row for every index built over a table partition or table member. Indexes that share another index's binary tree are not included. If the table is a distributed table, the indexes over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSPARTITIONINDEXSTAT view:

Table 199. SYSPARTITIONINDEXSTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
PARTITION_NUMBER	PARTNBR	INTEGER Nullable	The partition number of this partition. If the table is a distributed table, contains null.
NUMBER DISTRIBUTED PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
INDEX_SCHEMA	INDSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the index, logical file, or constraint.
INDEX_NAME	INDNAME	VARCHAR(128)	Name of the index, logical file, or constraint.
INDEX_MEMBER	INDMEMBER	VARCHAR(128) Nullable	Name of the member of the index or logical file. If the index type is a constraint, the member name is null.
INDEX_TYPE	INDTYPE	VARCHAR(11)	The type of the index: INDEX The index is an SQL index. LOGICAL The index is part of a logical file. PHYSICAL The index is part of a keyed physical file. PRIMARY KEY The index is a primary key constraint. UNIQUE The index is a unique constraint. REFERENTIAL The index is a foreign key constraint.

Table 199. SYSPARTITIONINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
NUMBER_KEY_COLUMNS	INDKEYS	BIGINT	Number of columns that define the index key.
COLUMN_NAMES	COLNAMES	VARCHAR(1024)	A comma separated list of column names that define the index key. If the length of all the column names exceeds 1024, '...' is returned at the end of the column value.
NUMBER_LEAF_PAGES	NLEAF	BIGINT	Not applicable for Db2 for i. Will always be -1.
NUMBER_LEVELS	NLEVELS	SMALLINT	Not applicable for Db2 for i. Will always be -1.
FIRSTKEYCARD	KEYCARD1	BIGINT	Number of distinct first key values. If the index is an encoded vector index, this is the total number of unique values for the entire index key.
FIRST2KEYCARD	KEYCARD2	BIGINT	Number of distinct keys using the first two columns of the index. If the index is an encoded vector index, -1 is returned.
FIRST3KEYCARD	KEYCARD3	BIGINT	Number of distinct keys using the first three columns of the index. If the index is an encoded vector index, -1 is returned.
FIRST4KEYCARD	KEYCARD4	BIGINT	Number of distinct keys using the first four columns of the index. If the index is an encoded vector index, -1 is returned.
FULLKEYCARD	KEYCARDF	BIGINT	Number of distinct full key values. If the index has more than 4 key columns or is an encoded vector index, -1 is returned.
CLUSTERRATIO	CLSRATIO	SMALLINT	Not applicable for Db2 for i. Will always be -1.
CLUSTERFACTOR	CLSFACTOR	DOUBLE	Not applicable for Db2 for i. Will always be -1.
SEQUENTIAL_PAGES	SEQPAGES	BIGINT	Not applicable for Db2 for i. Will always be -1.
DENSITY	DENSITY	INTEGER	Not applicable for Db2 for i. Will always be -1.
PAGE_FETCH_PAIRS	FETCHPAIRS	VARCHAR(520)	Not applicable for Db2 for i. Will always be an empty string.
NUMBER_KEYS	NUMRIDS	BIGINT	Number of keys in the index. If the index is invalid or is an encoded vector index, -1 is returned.
NUMRIDS_DELETED	NUMRIDSDLT	BIGINT	Not applicable for Db2 for i. Will always be 0.
NUM_EMPTY_LEAFS	EMPTYLEAFS	BIGINT	Not applicable for Db2 for i. Will always be 0.
AVERAGE_RANDOM_FETCH_PAGES	AVGRNDFTCH	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_RANDOM_PAGES	AVGRNDPAGE	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_GAP	AVGSEQGAP	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_FETCH_GAP	AVGSEQFGAP	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_PAGES	AVGSEQPAGE	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_FETCH_PAGES	AVGSEQFPAG	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVGPARTITION_CLUSTERRATIO	PCLSRATIO	SMALLINT	Not applicable for Db2 for i. Will always be -1.
AVGPARTITION_CLUSTERFACTOR	PCLSFACTOR	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVGPARTITION_PAGE_FETCH_PAIRS	PFETCHPAIR	VARCHAR(520)	Not applicable for Db2 for i. Will always be an empty string.
DATAPARTITION_CLUSTERFACTOR	DCLSFACTOR	DOUBLE	A statistic measuring the "clustering" of the index keys with regard to data partitions. It is a number between 0 and 1, with 1 representing perfect clustering and 0 representing no clustering.
INDCARD	INDCARD	BIGINT	Number of keys in the index. If the index is invalid or is an encoded vector index, -1 is returned.

Table 199. SYSPARTITIONINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
INDEX_VALID	VALID	CHAR(1)	An indication of whether the index is invalid and needs to be rebuilt: 0 The index is invalid. 1 The index is valid. 2 The index was saved with STG(*FREE).
INDEX_HELD	HELD	CHAR(1)	An indication or whether a pending rebuild of the index is currently held by the user: 0 A rebuild of the index is not pending or is not held. 1 A pending rebuild of the index is held.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	The timestamp when the index was created.
LAST_BUILD_TIMESTAMP	LASTBUILD	TIMESTAMP	The timestamp when the index was last rebuilt.
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	The timestamp of the last time the index was used in a query since the last time the usage statistics were reset. If the index has never been used in a query since the last time the usage statistics were reset, contains null.
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	The timestamp of the last time the index was used by the optimizer for statistics since the last time the usage statistics were reset. If the index has never been used for statistics since the last time the usage statistics were reset, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	The number of times the index was used in a query since the last time the usage statistics were reset. If the index has never been used in a query since the last time the usage statistics were reset, contains 0.
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	The number of times the index was used by the optimizer for statistics since the last time the usage statistics were reset. If the index has never been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the index was used directly by an application for native record I/O or SQL operations. If the index has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the index was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the index has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the index. For more information see the Change Object Description (CHGOBJD) command. If the index's last used timestamp has never been reset, contains null.
INDEX_SIZE	SIZE	BIGINT	Size (in bytes) of the data space index used by the index.
ESTIMATED_BUILD_TIME	ESTBLDTIME	INTEGER	Estimated time (in seconds) required to rebuild the index.
LAST_BUILD_TIME	LSTBLDTIME	INTEGER Nullable	Elapsed time (in seconds) the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_KEYS	LSTBLDKEYS	BIGINT Nullable	Number of keys the last time the index was built. Contains null if the last build information is not available.

Table 199. SYSPARTITIONINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
LAST_BUILD_DEGREE	LSTBLDDEG	SMALLINT Nullable	Parallel degree the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_TYPE	LSTBLDTYPE	CHAR(1) Nullable	An indication of whether the last index build was a complete build or a build from the delayed maintenance keys: 0 The last rebuild of the index was from the delayed maintenance keys. 1 The last build or rebuild of the index was a complete build from the rows in the table. If the index has never been built, contains null.
LAST_INVALIDATION_TIMESTAMP	LSTINVAL	TIMESTAMP Nullable	An indication of when the index was last invalidated. If the index has never been invalidated, contains null.
LAST_INVALIDATION_REASON_CODE	LSTINVRC	SMALLINT Nullable	The reason code when the index was last invalidated. Reason code values are listed in the SYSINDEXSTAT view. If the index has never been invalidated, contains null.
LAST_INVALIDATION_REASON_TYPE	LSTINVRT	SMALLINT Nullable	The reason type when the index was last invalidated. Reason type values are listed in the SYSINDEXSTAT view. If the index has never been invalidated, contains null.
DELAYED_MAINT_KEYS	DLYKEYS	INTEGER Nullable	Number of keys that need to be inserted into the binary tree of a delayed maintenance index. If the index is not a delayed maintenance index, contains null.
SPARSE	SPARSE	CHAR(1)	Indicates whether the index contains keys for all the rows of its depended on table: 0 The index contains keys for all the rows of its depended on table. 1 The index is a select/omit logical file or SQL index with a WHERE clause and does not contain keys for all the rows of its depended on table.
DERIVED_KEY	DERIVED	CHAR(1)	Indicates whether the any key columns in the index are expressions: 0 No key columns of the index are expressions. 1 At least one key column is an expression.
PARTITIONED	PARTITION	CHAR(1)	Indicates whether the index is partitioned or not partitioned: 0 An SQL index is not partitioned (spans multiple partitions). 1 The index is not built over a partitioned table or built over a partitioned table and is partitioned (does not span multiple partitions or members). 2 The index is a logical file built over multiple partitions or members.

Table 199. SYSPARTITIONINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
ACCPTH_TYPE	ACCPHTYPE	CHAR(1)	Indicates the type of index: 0 The index is a maximum 1 terabyte (*MAX1TB) binary radix index. 1 The index is a maximum 4 gigabyte (*MAX4GB) binary radix index. 2 The index is an encoded vector index.
UNIQUE	UNIQUE	CHAR(1)	Indicates whether an index is unique: 0 The index is a UNIQUE index. 1 The index is a UNIQUE WHERE NOT NULL index. 2 The index is a non-unique first-in-first-out (FIFO) index. 3 The index is a non-unique last-in-last-out (LIFO) index. 4 The index is a non-unique first-change-first-out (FCFO) index.
SRTSEQ_TYPE	SRTSEQ	CHAR(1)	Indicates whether the index uses a collating sequence: 0 The index does not use a collating table. 1 The index uses an alternate collating sequence (ALTSEQ). 2 The index uses a sort sequence (SRTSEQ).
LOGICAL_PAGE_SIZE	PAGE_SIZE	INTEGER Nullable	The logical page size of the index. If the index is an encoded vector index, contains null.
OVERFLOW_VALUES	OVERFLOW	INTEGER Nullable	The number of distinct key values that have overflowed the encoded vector index. If the index is not an encoded vector index, contains null.
EVI_CODE_SIZE	CODE_SIZE	INTEGER Nullable	The size of the byte code of the encoded vector index. If the index is not an encoded vector index, contains null.
LOGICAL_READS	LGLREADS	BIGINT	Number of logical read operations for the index since the last IPL.
PHYSICAL_READS	PHYREADS	BIGINT	Not applicable for Db2 for i. Will always be 0.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the index since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the index since the last IPL.
SEARCH_CONDITION	IXWWHERECON	VARGRAPHIC(1024) CCSID 1200	If an index is sparse, the search condition of the index. If the length of the search condition exceeds 1024, '...' is returned at the end of the column value.
KEEP_IN_MEMORY	KEEPINMEM	CHAR(1)	Indicates whether the index should be kept in memory: 0 No memory preference. 1 The index should be kept in memory, if possible.

Table 199. SYSPARTITIONINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
MEDIA_PREFERENCE	MEDIAPREF	SMALLINT	Indicates the media preference of the index: 0 No media preference. 255 The index should be allocated on Solid State Disk (SSD), if possible.
INCLUDE_EXPRESSION	IXINCEXPR	VARGRAPHIC(1024) CCSID 1200 Nullable	Index INCLUDE expression. Contains null if the index does not have an INCLUDE expression.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPARTITIONMQTS

The SYSPARTITIONMQTS view contains one row for every materialized table built over a table partition or table member. If the table is a distributed table, the materialized tables over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

Use this view when you want to see materialized query table information for materialized tables built on a specified table or set of tables. The information is similar to that returned via Show Materialized Query Tables in System i Navigator.

The following table describes the columns in the SYSPARTITIONMQTS view:

Table 200. SYSPARTITIONMQTS view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.
MQT_NAME	MQTNAME	VARCHAR(128)	Name of the materialized query table.
MQT_SCHEMA	MQTSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the materialized query table.
MQT_PARTITION	MQTMEMBER	VARCHAR(128)	Partition or member name of the materialized query table.
MQT_OWNER	MQOWNER	VARCHAR(128)	Materialized query table owner.
SYSTEM_MQT_SCHEMA	SYS_MQDNAM	CHAR(10)	System materialized query table schema name.
SYSTEM_MQT_NAME	SYS_MQNAME	CHAR(10)	System materialized query table name.
ENABLED	ENABLED	VARCHAR(3)	An indication or whether the materialized query table is enabled: NO The materialized query table is not enabled for use. YES The materialized query table is enabled for use by the database manager.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	The timestamp when the materialized query table was created.
REFRESH_TIME	REFRESHDTS	TIMESTAMP Nullable	The timestamp when the materialized query table was last refreshed. Contains null if the materialized query table has never been refreshed.

Table 200. SYSPARTITIONMQTS view (continued)

Column name	System Column Name	Data Type	Description
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains null.
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used by the optimizer for statistics since the last time the usage statistics were reset. If the materialized query table has never been used for statistics since the last time the usage statistics were reset, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	The number of times the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains 0.
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	The number of times the materialized query table was used by the optimizer for statistics since the last time the usage statistics were reset. If the materialized query table has never been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was used directly by an application for native record I/O or SQL operations. If the materialized query table has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the materialized query table was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the materialized query table has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the materialized query table. For more information see the Change Object Description (CHGOBJD) command. If the materialized query table's last used timestamp has never been reset, contains null.
NUMBER_ROWS	CARD	BIGINT	Number of rows in the materialized query table.
MQT_SIZE	SIZE	BIGINT	Size (in bytes) of the materialized query table.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP Nullable	The timestamp of the last time the materialized query table was changed. If the materialized query table has never been changed since the last time the usage statistics were reset, contains null.
MAINTENANCE	MAINTAIN	VARCHAR(6)	Indicates the maintenance for the materialized query table: SYSTEM The materialized query table is system maintained. USER The materialized query table is user maintained.
INITIAL_DATA	INITIAL	VARCHAR(19)	Indicates the initial data for the materialized query table: INITIALLY DEFERRED Data is not inserted into the materialized query table when it is created. INITIALLY IMMEDIATE Data is inserted into the materialized query table when it is created.

Table 200. SYSPARTITIONMQTS view (continued)

Column name	System Column Name	Data Type	Description
REFRESH	REFRESH	VARCHAR(9)	<p>Indicates when the data in the materialized query table can be refreshed:</p> <p>DEFERRED Data in the materialized query table can be refreshed at any time using the REFRESH TABLE statement.</p> <p>IMMEDIATE Data in the materialized query table is immediately refreshed.</p>
ISOLATION	ISOLATION	VARCHAR(27)	<p>Indicates the isolation level used to refresh the materialized query table:</p> <p>NO COMMIT The isolation level is NO COMMIT.</p> <p>UNCOMMITTED READ The isolation level is UNCOMMITTED READ.</p> <p>CURSOR STABILITY The isolation level is CURSOR STABILITY.</p> <p>CURSOR STABILITY KEEP LOCKS The isolation level is CURSOR STABILITY KEEP LOCKS.</p> <p>READ STABILITY The isolation level is READ STABILITY.</p> <p>REPEATABLE READ The isolation level is REPEATABLE READ.</p>
SORT_SEQUENCE	SRTSEQ	VARCHAR(12)	<p>Indicates whether the materialize query table uses a collating sequence:</p> <p>BY HEX VALUE The materialize query table does not use a collating table.</p> <p>*LANGIDSHR The materialize query table uses a shared weight sort sequence (SRTSEQ).</p> <p>*LANGIDUNQ The materialize query table uses a unique weight sort sequence (SRTSEQ).</p> <p>ALTSEQ The materialize query table uses an alternate collating sequence (ALTSEQ).</p>
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	The language ID of the materialize query table. Contains null if the sort sequence is hex.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10) Nullable	Schema name of the sort sequence to use. Contains null if there is no schema name.
SORT_SEQUENCE_NAME	SRTSEQNAM	CHAR(10) Nullable	Name of the sort sequence to use. Contains null if there is no sort sequence name.
MQT_RESTORE_DEFERRED	MQTRSTDFR	VARCHAR(3)	<p>An indication of whether a restore of the MQT is pending the restore of one of its dependents:</p> <p>NO The restore of the MQT is not deferred pending the restore of one of its dependent tables.</p> <p>YES The restore of the MQT is deferred pending the restore of one of its dependent tables.</p>

Table 200. SYSPARTITIONMQTS view (continued)

Column name	System Column Name	Data Type	Description
ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode of the materialized query table: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP Contains the null value if the materialized query table does not have an expression that references a DECFLOAT column, function, or constant.
DECFLOAT_WARNING	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether DECFLOAT warnings are returned: NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned. Contains the null value if the materialized query table does not have an expression that references a DECFLOAT column, function, or constant.
MQT_DEFINITION	MQTDEF	VARGRAPHIC(5000) CCSID 1200	The query of the materialized query table. If the length of the query exceeds 5000, '...' is returned at the end of the column value.
MQT_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the materialized query table. Contains null if text does not exist for the materialized query table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPARTITIONSTAT

The SYSPARTITIONSTAT view contains one row for every table partition or table member. If the table is a distributed table, the partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

Similar information that includes one row for every file member, including program described files, is available with the SYSMEMBERSTAT view: [QSYS2.SYSMEMBERSTAT](#)

The following table describes the columns in the SYSPARTITIONSTAT view:

Table 201. SYSPARTITIONSTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table partition or member.

Table 201. SYSPARTITIONSTAT view (continued)

Column name	System Column Name	Data Type	Description
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
PARTITION_NUMBER	PARTNBR	INTEGER Nullable	The partition number of this partition. If the table is a distributed table, contains null.
NUMBER_DISTRIBUTED_PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
NUMBER_ROWS	CARD	BIGINT	Number of valid rows in the table partition or member.
NUMBER_ROW_PAGES	NPAGES	BIGINT	Number of 64K pages in the partition's data.
NUMBER_PAGES	FPAGES	BIGINT	Same as NUMBER_ROW_PAGES.
OVERFLOW	OVERFLOW	BIGINT	The estimated number of rows that have overflowed to variable length segments. If the table does not contain variable length or LOB columns, contains 0.
CLUSTERED	CLUSTERED	CHAR(1) Nullable	Not applicable for Db2 for i. Will always be null.
ACTIVE_BLOCKS	ACTBLOCKS	BIGINT	Not applicable for Db2 for i. Will always be -1.
AVGCOMPRESSEDROWSIZE	ACROWSIZE	BIGINT	Not applicable for Db2 for i. Will always be -1.
AVGROWCOMPRESSIONRATIO	ACROWRATIO	REAL	Not applicable for Db2 for i. Will always be -1.
AVGROWSIZE	AVGROWSIZE	BIGINT	Average length (in bytes) of a row in this table. If the table has variable length or LOB columns, contains -1.
PCTROWSCOMPRESSED	PCTCROWS	REAL	Not applicable for Db2 for i. Will always be -1.
PCTPAGESSAVED	PCTPGSAVED	SMALLINT	Not applicable for Db2 for i. Will always be -1.
NUMBER_DELETED_ROWS	DELETED	BIGINT	Number of deleted rows in the table partition or member.
DATA_SIZE	SIZE	BIGINT	Total size (in bytes) of the data space in the partition or member.
VARIABLE_LENGTH_SIZE	VLSIZE	BIGINT	Size (in bytes) of the variable-length data space segments in the partition or member.
VARIABLE_LENGTH_SEGMENTS	VLSEGMENTS	BIGINT	The number of variable-length data space segments in the partition or member.
FIXED_LENGTH_EXTENTS	FLEXENTS	BIGINT	Not applicable for Db2 for i. Will always be -1.
VARIABLE_LENGTH_EXTENTS	VLEXTENTS	BIGINT	Not applicable for Db2 for i. Will always be -1.
COLUMN_STATS_SIZE	CSTATSSIZE	BIGINT	Size (in bytes) of the column statistics in the partition or member.
MAINTAINED_TEMPORARY_INDEX_SIZE	MTISIZE	BIGINT	Size (in bytes) of all maintained temporary indexes over the partition or member.
NUMBER_DISTINCT_INDEXES	DISTINCTIX	INTEGER	The number of distinct indexes built over the partition or member. This does not include maintained temporary indexes.
OPEN_OPERATIONS	OPENS	BIGINT	Number of full opens of the partition or member since the last IPL.
CLOSE_OPERATIONS	CLOSES	BIGINT	Number of full closes of the partition or member since the last IPL.

Table 201. SYSPARTITIONSTAT view (continued)

Column name	System Column Name	Data Type	Description
INSERT_OPERATIONS	INSERTS	BIGINT	Number of insert operations for the partition or member since the last IPL.
BLOCKED_INSERT_OPERATIONS	BLKIOPS	BIGINT	Number of blocked insert operations for the partition or member since the last IPL.
BLOCKED_INSERT_ROWS	BLKIROW	BIGINT	Number of rows inserted with blocked insert operations for the partition or member since the last IPL.
UPDATE_OPERATIONS	UPDATES	BIGINT	Number of update operations for the partition or member since the last IPL.
DELETE_OPERATIONS	DELETES	BIGINT	Number of delete operations for the partition or member since the last IPL.
CLEAR_OPERATIONS	DSCLEARS	BIGINT	Number of clear operations (CLRPFM operations) for the partition or member since the last IPL.
COPY_OPERATIONS	DESCOPIES	BIGINT	Number of data space copy operations (certain CPYxxx operations) for the partition or member since the last IPL.
REORGANIZE_OPERATIONS	DSREORGs	BIGINT	Number of data space reorganize operations (non-interruptible RGZPFM operations) for the partition or member since the last IPL.
INDEX_BUILDS	DSINXBLLS	BIGINT	Number of creates or rebuilds of indexes that reference the partition or member since the last IPL. This does not include maintained temporary indexes.
LOGICAL_READS	LGLREADS	BIGINT	Number of logical read operations for the partition or member since the last IPL.
PHYSICAL_READS	PHYREADS	BIGINT	Number of physical read operations for the partition or member since the last IPL.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the partition or member since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the partition or member since the last IPL.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	Create timestamp of the partition or member.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP	Timestamp of the last change that occurred to the partition or member.
LAST_SAVE_TIMESTAMP	LASTSAVE	TIMESTAMP Nullable	Timestamp of the last save of the partition or member. If the partition or member has never been saved, contains null.
LAST_RESTORE_TIMESTAMP	LASTRST	TIMESTAMP Nullable	Timestamp of the last restore of the partition or member. If the partition or member has never been restored, contains null.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	Timestamp of the last time the partition or member was used directly by an application for native record I/O or SQL operations. If the partition or member has never been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the partition or member was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the partition or member has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the table. For more information see the Change Object Description (CHGOBJD) command. If the partition or member's last used timestamp has never been reset, contains null.
NEXT_IDENTITY_VALUE	NEXTVALUE	DECIMAL(31,0) Nullable	The next identity value. In some cases, this value may be an estimate. If the table does not have an identity value, contains null.

Table 201. SYSPARTITIONSTAT view (continued)

Column name	System Column Name	Data Type	Description
LOWINCLUSIVE	LOWINCL	CHAR(1) Nullable	Indicates whether the low key value for the partition is inclusive. N The low key value is not inclusive. Y The low key value is inclusive. If the table is not partitioned by range, contains null.
LOWVALUE	LOWVALUE	VARGRAPHIC(1024) CCSID 1200 Nullable	A string representation of the low key value for a range partition. If the table is not partitioned by range, contains null.
HIGHINCLUSIVE	HIGHINCL	CHAR(1) Nullable	Indicates whether the high key value for the partition is inclusive. N The high key value is not inclusive. Y The high key value is inclusive. If the table is not partitioned by range, contains null.
HIGHVALUE	HIGHVALUE	VARGRAPHIC(1024) CCSID 1200 Nullable	A string representation of the high key value for a range partition. If the table is not partitioned by range, contains null.
NUMBER_PARTITIONING_KEYS	NBRPKEYS	INTEGER Nullable	The number of partitioning keys. If the table is not partitioned, contains null.
PARTITIONING_KEYS	PARTKEYS	VARCHAR(2880) Nullable	The list of partitioning keys. If the table is not partitioned, contains null.
KEEP_IN_MEMORY	KEEPINMEM	CHAR(1)	Indicates whether the partition should be kept in memory: 0 No memory preference. 1 The partition should be kept in memory, if possible.
MEDIA_PREFERENCE	MEDIAPREF	SMALLINT	Indicates the media preference of the partition: 0 No media preference. 255 The partition should be allocated on Solid State Disk (SSD), if possible.
LAST_SOURCE_UPDATE_TIMESTAMP	LASTSRCUPD	TIMESTAMP Nullable	Last source change timestamp to a source member. If the table is not a source file, contains null.
SOURCE_TYPE	SRCTYPE	VARCHAR(10) Nullable	Source type of a source member. If the table is not a source file, contains null.
VOLATILE	VOLATILE	CHAR(1)	Indicates whether the table is volatile. 0 Table is not volatile. 1 Table is volatile.
PARTITION_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Text of the partition. Contains null if text does not exist for the partition.

Table 201. SYSPARTITIONSTAT view (continued)

Column name	System Column Name	Data Type	Description
PARTIAL_TRANSACTION	PARTIALTX	CHAR(1)	Indicates whether the partition contains a partial transaction: N The partition does not contain a partial transaction. Y The partition was saved while active with a partial transaction. A subsequent restore of the partition contains the partial transaction. The user should apply changes from the journal to complete the transaction. R A rollback abnormally ended prior to completion. This left the partition with a partial set of rolled back rows.
APPLY_STARTING_RECEIVER_LIBRARY	APYRCVLIB	VARCHAR(10) Nullable	The library containing the starting journal receiver. Contains null if APPLY_STARTING_RECEIVER is null.
APPLY_STARTING_RECEIVER	APYRCVNAME	VARCHAR(10) Nullable	Indicates that the partition was saved and subsequently restored. If the table was journaled when the partition was saved, the starting journal receiver name will indicate the journal receiver to start with if APYJRNCHG is then used. Contains null if PARTIAL_TRANSACTION has a value of R. Once an APYJRNCHG is performed, the apply information is cleared.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	CHAR(10)	System member name.

SYSPERIODS

The SYSPERIODS view contains one row for every period defined for a temporal table in an SQL schema.

The following table describes the columns in the SYSPERIODS view:

Table 202. SYSPERIODS view

Column name	System Column Name	Data Type	Description
PERIOD_NAME	PERIODNAME	VARCHAR(128)	Name of the period.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the temporal table.
BEGIN_COLUMN_NAME	BGNCOLNAME	VARCHAR(128)	Period begin column name.
END_COLUMN_NAME	ENDCOLNAME	VARCHAR(128)	Period end column name
PERIOD_TYPE	PERIODTYPE	CHAR(1)	The type of period for this row: S System period
HISTORY_TABLE_SCHEMA	HSTDBNAME	VARCHAR(128) Nullable	Schema name of the history table. Contains the null value if versioning has not been added to the system-period temporal table.
HISTORY_TABLE_NAME	HSTTBNAME	VARCHAR(128) Nullable	Name of the history table. Contains the null value if versioning has not been added to the system-period temporal table.

Table 202. SYSPERIODS view (continued)

Column name	System Column Name	Data Type	Description
ON_DELETE_ADD_EXTRA_ROW	ADD_ROW	VARCHAR(3) Nullable	Versioning defined with ON DELETE ADD EXTRA ROW. YES ON DELETE ADD EXTRA ROW was specified. NO ON DELETE ADD EXTRA ROW was not specified. Contains the null value if versioning has not been added to the system-period temporal table.
VERSIONING_STATUS	VERSIONSTS	CHAR(1) Nullable	Status of versioning E A versioning relationship between the system-period temporal table and the history table has been established. The history table is being used to store previous versions of the system-period temporal table's modified rows. D A versioning relationship between the system-period temporal table and the history table has been defined but not established. Operations on the system-period temporal table will be prevented until the versioning relationship is established or versioning of the system-period temporal table is removed. Contains the null value if versioning has not been added to the system-period temporal table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name of temporal table.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of temporal table.
SYSTEM_HISTORY_TABLE_SCHEMA	SYSHSTLIB	CHAR(10) Nullable	System schema name of the history table. Contains the null value if versioning has not been added to the system-period temporal table.
SYSTEM_HISTORY_TABLE_NAME	SYSHSTNAME	CHAR(10) Nullable	System name of the history table. Contains the null value if versioning has not been added to the system-period temporal table.
SYSTEM_BEGIN_COLUMN_NAME	SYSBGNCOL	CHAR(10)	Period begin system column name.
SYSTEM_END_COLUMN_NAME	SYSENDCOL	CHAR(10)	Period end system column name

SYSPROCS

The SYSPROCS view contains one row for each procedure created by the CREATE PROCEDURE statement.

The following table describes the columns in the SYSPROCS view:

Table 203. SYSPROCS view

Column Name	System Column Name	Data Type	Description
SPECIFIC_SCHEMA	SPECSCHEMA	VARCHAR(128)	Schema name of the routine (procedure) instance.
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine instance.
ROUTINE_SCHEMA	PROCSchema	VARCHAR(128)	Name of the SQL schema (schema) that contains the routine.
ROUTINE_NAME	PROCNAME	VARCHAR(128)	Name of the routine.
ROUTINE_CREATED	RTNCREATE	TIMESTAMP	Identifies the timestamp when the routine was created.
ROUTINE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the routine.

Table 203. SYSPROCS view (continued)

Column Name	System Column Name	Data Type	Description
ROUTINE_BODY	BODY	VARCHAR(8)	The type of the routine body: EXTERNAL This is an external routine. SQL This is an SQL routine.
EXTERNAL_NAME	EXTNAME	VARCHAR(279) Nullable	This column identifies the external program name. <ul style="list-style-type: none">• For ILE service programs, the external program name is <i>schema-name/service-program-name(entry-point-name)</i>.• For REXX, the external program name is <i>schema-name/source-file-name(member-name)</i>.• For Java programs, the external program name is an optional jar-id followed by a <i>fully-qualified-class-name/method-name</i> or <i>fully-qualified-class-name.method-name</i>.• For all other languages, the external program name is <i>schema-name/program-name</i>.
EXTERNAL_LANGUAGE	LANGUAGE	VARCHAR(8) Nullable	If this is an external routine, this column identifies the external program's language. C The external program is written in C. C++ The external program is written in C++. CL The external program is written in CL. COBOL The external program is written in COBOL. COBOLLE The external program is written in ILE COBOL. FORTRAN The external program is written in FORTRAN. JAVA The external program is written in JAVA. PLI The external program is written in PL/I. REXX The external program is a REXX procedure. RPG The external program is written in RPG. RPGLE The external program is written in ILE RPG. Contains the null value if this is not an external routine.
PARAMETER_STYLE	PARM_STYLE	VARCHAR(7) Nullable	If this is an external routine, this column identifies the parameter style (calling convention). DB2GNRL This is the DB2GENERAL calling convention. DB2SQL This is the DB2SQL calling convention. GENERAL This is the GENERAL calling convention. JAVA This is the JAVA calling convention. NULLS This is the GENERAL WITH NULLS calling convention. SQL This is the SQL standard calling convention. Contains the null value if this is not an external routine.

Table 203. SYSPROCS view (continued)

Column Name	System Column Name	Data Type	Description
IS_DETERMINISTIC	DETERMINE	VARCHAR(3)	<p>This column identifies whether the routine is deterministic. That is, whether a call to the routine with the same arguments will always return the same result.</p> <p>NO The routine is not deterministic.</p> <p>YES The routine is deterministic.</p>
SQL_DATA_ACCESS	DATAACCESS	VARCHAR(8)	<p>This column identifies whether a routine contains SQL and whether it reads or modifies data.</p> <p>NONE The routine does not contain any SQL statements.</p> <p>CONTAINS The routine contains SQL statements.</p> <p>READS The routine possibly reads data from a table or view.</p> <p>MODIFIES The routine possibly modifies data in a table or view or issues SQL DDL statements.</p>
SQL_PATH	SQL_PATH	VARCHAR(3483) Nullable	<p>If this is an SQL routine, this column identifies the path.</p> <p>Contains the null value if this is not an SQL routine.</p>
PARM_SIGNATURE	SIGNATURE	VARCHAR(16000)	This column identifies the routine signature.
RESULT_SETS	RESULTS	SMALLINT	Identifies the maximum number of result sets returned. 0 indicates that there are no result sets.
IN_PARMS	IN_PARMS	SMALLINT	Identifies the number of input parameters. 0 indicates that there are no input parameters.
OUT_PARMS	OUT_PARMS	SMALLINT	Identifies the number of output parameters. 0 indicates that there are no output parameters.
INOUT_PARMS	INOUT_PARM	SMALLINT	Identifies the number of input/output parameters. 0 indicates that there are no input/output parameters.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	<p>A character string supplied with the COMMENT statement.</p> <p>Contains the null value if there is no long comment.</p>
ROUTINE_DEFINITION	ROUTINEDEF	DBCLOB(2M) CCSID 13488 Nullable	<p>If this is an SQL routine, this column contains the SQL routine body.</p> <p>If this is an obfuscated routine, the text starts with the WRAPPED keyword and is followed by the encoded form of the statement text.</p> <p>Contains the null value if this is not an SQL routine.</p>
DBINFO	DBINFO	VARCHAR(3) Nullable	<p>Identifies whether information about the database is passed to the procedure.</p> <p>NO No database information is passed to the procedure.</p> <p>YES Information about the database is passed to the procedure.</p>

Table 203. SYSPROCS view (continued)

Column Name	System Column Name	Data Type	Description
COMMIT_ON_RETURN	CMTONRET	VARCHAR(3) Nullable	This column identifies whether the procedure commits on a successful return from the procedure. NO A commit is not performed on successful return from the procedure. YES A commit is performed on successful return from the procedure. AUT Procedure will commit or rollback autonomously.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
NEW_SAVEPOINT_LEVEL	NEWSAVEPTL	VARCHAR(3) Nullable	This column identifies whether the routine starts a new savepoint level. NO A new savepoint level is not started. YES A new savepoint level is started.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	If this is an SQL procedure, identifies the DECFLOAT rounding mode. C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the procedure is not an SQL procedure.
ROUTINE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Contains the label for a routine. Contains the null value if a label does not exist.
AUTONOMOUS	AUTONOMOUS	VARCHAR(3)	This column identifies whether the procedure is autonomous. NO The procedure is not autonomous. YES The procedure is autonomous.

SYSPROGRAMSTAT

The SYSPROGRAMSTAT view contains one row for each program, service program, and module that contains SQL statements.

The following table describes the columns in the SYSPROGRAMSTAT view:

Table 204. SYSPROGRAMSTAT view

Column Name	System Column Name	Data Type	Description
PROGRAM_SCHEMA	COLLID	VARCHAR(128)	Name of the schema.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
PROGRAM_NAME	NAME	VARCHAR(128)	Name of the program, service program, or module. For an SQL procedure, function, or trigger, this is the SQL object name.
PROGRAM_TYPE	PGMTYPE	VARCHAR(128)	Type of the object *PGM The object is a program. *MODULE The object is a module. *SRVPGM The object is a service program.
MODULE_NAME	MODNAME	VARCHAR(10) Nullable	Module name for ILE program or service program. Contains the null value if this is not an ILE program or service program, or if the program or service program is not a procedure or function.
PROGRAM_OWNER	OWNER	VARCHAR(128)	Owner of the program, service program, or module
PROGRAM_CREATOR	CREATOR	VARCHAR(128)	Creator of the program, service program, or module
CREATION_TIMESTAMP	TIMESTAMP	TIMESTAMP	Timestamp of when the program, service program, or module was created
DEFAULT_SCHEMA	QUALIFIER	VARCHAR(128) Nullable	Implicit name for unqualified tables, views, and indexes. Contains the null value if a default schema was not specified (DFTRDBC0L) or if the program is an external routine without SQL statements.
ISOLATION	ISOLATION	CHAR(2) Nullable	Isolation option specification: RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NC No Commit (*NONE) Contains the null value if the program is an external routine without SQL statements.
CONCURRENTACCESSRESOLUTION	CONCURRENT	CHAR(1) Nullable	Specifies the concurrent access resolution: blank Not specified W Wait for outcome U Use currently committed Contains the null value if the program is an external routine without SQL statements.
NUMBER_STATEMENTS	NBRSTMTS	INTEGER	Number of SQL statements in the program, service program or module.
PROGRAM_USED_SIZE	PGMSIZE	INTEGER	Number of bytes that are used for SQL statements and access plans in the program, service program or module.
NUMBER_COMPRESSIONS	PGM_CMP	INTEGER Nullable	Number of times the program or service program has been compressed. Contains the null value for modules or if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
STATEMENT_CONTENTION_COUNT	CONTENTION	BIGINT Nullable	Number of times contention occurred when attempting to store a new access plan. Contains the null value for modules or if the program is an external routine without SQL statements.
ORIGINAL_SOURCE_FILE	SOURCE	VARCHAR(128) Nullable	The fully qualified source file and member that was used to create the program or module. Contains the null value for SQL routines or if the program is an external routine without SQL statements.
ORIGINAL_SOURCE_FILE_CCSCID	SRC_CCSCID	INTEGER Nullable	The CCSCID of the source file that was used to create the program or module. Contains the null value for SQL routines or if the program is an external routine without SQL statements.
ROUTINE_TYPE	RTNTYPE	VARCHAR(9) Nullable	Type of the routine. PROCEDURE This is a procedure. FUNCTION This is a function. TRIGGER This is a trigger. Contains the null value for modules or if the program or service program is not a procedure, function, or trigger. An external procedure will not be identified as PROCEDURE unless NUMBER_EXTERNAL_ROUTINES is greater than zero.
ROUTINE_BODY	BODY	VARCHAR(8) Nullable	The type of the routine body: EXTERNAL This is an external routine. SQL This is an SQL routine. Contains the null value for modules or if the program or service program is not a procedure or function.
FUNCTION_ORIGIN	ORIGIN	CHAR(1) Nullable	Identifies the type of function. If this is a procedure, this column contains a blank. B This is a built-in function (defined by Db2 for i). E This is a user-defined function. U This is a user-defined function that is sourced on another function. S This is a system-generated function. Contains the null value for modules or if the program or service program is not a procedure or function.
FUNCTION_TYPE	TYPE	CHAR(1) Nullable	Identifies the form of the function. If this is a procedure, this column contains a blank. S This is a scalar function. C This is a column function. T This is a table function. Contains the null value for modules or if the program or service program is not a procedure, function, or trigger.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
NUMBER_EXTERNAL_ROUTINES	NBREXTRTN	SMALLINT Nullable	Indicates the number of procedure and function definitions stored in the program or service program. Contains the null value for modules, triggers, or SQL routines.
EXTENDED_INDICATOR	EXTIND	VARCHAR(9) Nullable	Indicates the EXTIND attribute: *EXTIND Extended indicator support is enabled. *NOEXTIND Extended indicator support is not enabled. Contains the null value if the program is an external routine without SQL statements.
C_NUL_REQUIRED	CNULRQD	VARCHAR(10) Nullable	Indicates the CNULRQD attribute: *CNULRQD C nuls are required. *NOCNULRQD C nuls are not required. Contains the null value if the program is an external routine without SQL statements.
NAMING	NAMING	VARCHAR(4) Nullable	Indicates the NAMING attribute: *SYS This is system naming. *SQL This is SQL naming. Contains the null value if the program is an external routine without SQL statements.
TARGET_RELEASE	TGTRLS	VARCHAR(6) Nullable	Indicates the target release of the program, service program, or module (VxRxMx). Contains the null value if the program is an external routine without SQL statements.
EARLIEST_POSSIBLE_RELEASE	MINRLS	VARCHAR(6) Nullable	Indicates the earliest IBM i release that supports all the SQL statements in the program, service program, or module (VxRxMx). *ANY The statements are valid on any supported IBM i release. VxRxMx The statement is valid on IBM i VxRxMx release or later. Contains the null value if the earliest release has not yet been determined or if the program is an external routine without SQL statements.
RDB	RDB	VARCHAR(18) Nullable	Indicates the RDB specified for the program, service program, or module. rdb-name The name of the relational database. *LOCAL The database on the local system. *NONE A relational database was not specified. Contains the null value if the program is an external routine without SQL statements.
CONSISTENCY_TOKEN	CONTOKEN	VARBINARY(8) Nullable	Indicates the consistency token of the program. Contains the null value if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
ALLOW_COPY_DATA	ALWCPYDTA	VARCHAR(9) Nullable	Indicates the ALWCPYDTA attribute: *NO A copy of the data is not allowed. *OPTIMIZE A copy of the data is allowed whenever it might result in better performance. *YES A copy of the data is allowed, but only when necessary. Contains the null value if the program is an external routine without SQL statements.
CLOSE_SQL_CURSOR	CLOSQLCSR	VARCHAR(10) Nullable	Indicates the CLOSQLCSR attribute: *ENDACTGRP SQL cursors are closed and SQL prepared statements are implicitly discarded, and LOCK TABLE locks are released when the activation group ends. *ENDJOB SQL cursors are closed and SQL prepared statements are implicitly discarded, and LOCK TABLE locks are released when the job ends. *ENDMOD SQL cursors are closed and SQL prepared statements are implicitly discarded when the module is exited. LOCK TABLE locks are released when the first SQL program on the call stack ends. *ENDPGM SQL cursors are closed and SQL prepared statements are implicitly discarded when the program ends. LOCK TABLE locks are released when the first SQL program on the call stack ends. Contains the null value if the program is an external routine without SQL statements.
LOB_FETCH_OPTIMIZATION	OPTLOB	VARCHAR(9)	Indicates the LOB optimization attribute: *OPTLOB The first FETCH for a cursor determines how the cursor will be used for LOB and XML result columns on all subsequent FETCHes. *NOOPTLOB Any FETCH may retrieve a LOB or XML result column into either a locator or variable.
DECIMAL_POINT	DECPNT	VARCHAR(7)	Indicates the decimal point for numeric constants used in SQL statements. *PERIOD The decimal point is a period. *COMMA The decimal point is a comma.
SQL_STRING_DELIMITER	STRDLM	VARCHAR(9)	Indicates the character used as the string delimiter in the SQL statements. *APOSTSQL The string delimiter is an apostrophe (''). *QUOTESQL The string delimiter is a quote ("").

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
DATE_FORMAT	DATFMT	VARCHAR(4)	Indicates the DATFMT attribute:
		Nullable	*JOB The date format specified in the job at runtime is used. *USA The date format is *USA. *ISO The date format is *ISO. *EUR The date format is *EUR. *JIS The date format is *JIS. *MDY The date format is *MDY. *DMY The date format is *DMY. *YMD The date format is *YMD. *JUL The date format is *JUL. Contains the null value if the program is an external routine without SQL statements.
DATE_SEPARATOR	DATSEP	CHAR(1)	Indicates the date separator.
		Nullable	Contains the null value if the program is an external routine without SQL statements.
TIME_FORMAT	TIMFMT	VARCHAR(4)	Indicates the TIMFMT attribute:
		Nullable	*JOB The time format specified in the job at runtime is used. *USA The time format is *USA. *ISO The time format is *ISO. *EUR The time format is *EUR. *JIS The time format is *JIS. *HMS The date format is *HMS. Contains the null value if the program is an external routine without SQL statements.
TIME_SEPARATOR	TIMSEP	CHAR(1)	Indicates the time separator.
		Nullable	Contains the null value if the program is an external routine without SQL statements.
DYNAMIC_DEFAULT_SCHEMA	DYNDFTCOL	VARCHAR(4)	Indicates whether the value for DFTRDBCOL should be used for implicit qualification on dynamic SQL statements:
		Nullable	*NO The schema specified in DFTDRBCOL is not used for dynamic SQL statements. *YES The schema specified in DFTDRBCOL is used for dynamic SQL statements. Contains the null value if a default schema was not specified (DFTRDBCOL) or if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
CURRENT_RULES	SQLCURRULE	VARCHAR(4) Nullable	Indicates the SQLCURRULE attribute: *DB2 The semantics of all SQL statements will default to the rules established for Db2. *STD The semantics of all SQL statements will default to the rules established by the ISO and ANSI SQL standards. Contains the null value if the program is an external routine without SQL statements.
ALLOW_BLOCK	ALWBLK	VARCHAR(8) Nullable	Indicates the ALWBLK attribute: *ALLREAD Rows are blocked for read-only cursors. *NONE Rows are not blocked for retrieval of data for cursors. *READ Records are blocked for read-only retrieval of data for cursors when: <ul style="list-style-type: none"> • *NONE is specified for the Commitment control (COMMIT) parameter. • The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor. Contains the null value if the program is an external routine without SQL statements.
DELAY_PREPARE	DLYPRP	VARCHAR(4) Nullable	Indicates the DLYPRP attribute: *NO Dynamic statement validation is performed when the dynamic statements are prepared. *YES Dynamic statement validation is delayed until the dynamic statements are used. Contains the null value if the program is an external routine without SQL statements.
USER_PROFILE	USRPRF	VARCHAR(7) Nullable	Specifies the user profile used for authority checking: *USER The profile of the user running the program is used. *OWNER The profiles of both the owner of the program and the user running the program is used. *NAMING If the naming convention is *SQL, *OWNER is used. If the naming convention is *SYS, *USER is used. Contains the null value if the program is an external routine without SQL statements.
DYNAMIC_USER_PROFILE	DYNUSRPRF	VARCHAR(6) Nullable	Specifies the user profile used for dynamic SQL statements: *USER Local dynamic SQL statements are run under the profile of the job or thread. Distributed dynamic SQL statements are run under the profile of the application server job. *OWNER Local dynamic SQL statements are run under the profile of the program's owner. Distributed dynamic SQL statements are run under the profile of the SQL package's owner. Contains the null value if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
SORT_SEQUENCE	SRTSEQ	VARCHAR(12) Nullable	Indicates whether the program, service program, or module uses a collating sequence: BY HEX VALUE The SQL index does not use a collating table. *LANGIDSHR The SQL index uses a shared weight sort sequence (SRTSEQ). *LANGIDUNQ The SQL index uses a unique weight sort sequence (SRTSEQ). ALTSEQ The SQL index uses an alternate collating sequence (ALTSEQ). Contains the null value if the program is an external routine without SQL statements.
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	The language ID sort sequence. Contains the null value if the sort sequence is not *LANGIDSHR or *LANGIDUNQ or if the program is an external routine without SQL statements.
SORT_SEQUENCE_SCHEMA	SRTSEQSCH	CHAR(10) Nullable	The sort sequence table system schema. Contains the null value if the sort sequence is hex or if the program is an external routine without SQL statements.
SORT_SEQUENCE_NAME	SRTSEQNAME	CHAR(10) Nullable	The sort sequence table name. Contains the null value if the sort sequence is hex or if the program is an external routine without SQL statements.
RDB_CONNECTION_METHOD	RDBCNNMTH	VARCHAR(4) Nullable	Specifies the semantics used for CONNECT statements: *RUW CONNECT (Type 1) semantics are used to support remote unit of work. *DUW CONNECT (Type 2) semantics are used to support distributed unit of work. Contains the null value if the program is an external routine without SQL statements.
DECRESULT_MAXIMUM_PRECISION	DECMAXPRC	SMALLINT Nullable	Specifies the maximum precision. 31 The maximum precision is 31. 63 The maximum precision is 63. Contains the null value if the program is an external routine without SQL statements.
DECRESULT_MAXIMUM_SCALE	DECMAXSCL	SMALLINT Nullable	The maximum scale (number of decimal positions to the right of the decimal point) that should be returned for result data types. Contains the null value if the program is an external routine without SQL statements.
DECRESULT_MINIMUM_DIVIDE_SCALE	DECMINDIV	SMALLINT Nullable	The minimum divide scale (number of decimal positions to the right of the decimal point) that should be returned for both intermediate and result data types. Contains the null value if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
DECFLOAT_ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Indicates the DECFLOAT rounding mode: CEILING ROUND_CEILING DOWN ROUND_DOWN FLOOR ROUND_FLOOR HALFDOWN ROUND_HALF_DOWN HALFEVEN ROUND_HALF_EVEN HALFUP ROUND_HALF_UP UP ROUND_UP Contains the null value if the program is an external routine without SQL statements.
DECFLOAT_WARNING	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether DECFLOAT warnings are returned. NO DECFLOAT warnings are not returned. YES DECFLOAT warnings are returned. Contains the null value if the program is an external routine without SQL statements.
SQLPATH	SQLPATH	VARCHAR(3483) Nullable	Identifies the SQL path. Contains the null value if an SQL path is not specified or if the program is an external routine without SQL statements.
DBGVIEW	DBGVIEW	VARCHAR(9) Nullable	Specifies the type of source debug information: *NONE No debug. *SOURCE Debug view includes source and SQL INCLUDE statements. *STMT Debug view includes precompiler generated statements. *LIST Debug view includes the compiled listing. *LSTDBG Debug view includes the compiled listing of an OPM program. ALLOW Source debug allowed by the Unified Debugger. DISALLOW Source debug not allowed by the Unified Debugger. DISABLE Source debug not allowed by the Unified Debugger and the DEBUG MODE cannot be altered. Contains the null value if the program is an external routine without SQL statements.

Table 204. SYSPROGRAMSTAT view (continued)

Column Name	System Column Name	Data Type	Description
DBGKEY	DBGKEY	VARCHAR(3) Nullable	Specifies the type of source debug information: NO No encryption key was specified on the debug encryption key (DBGENKEY) parameter. YES A key was specified on the debug encryption key (DBGENKEY) parameter. Contains the null value if DBGENKEY is not supported or if the program is an external routine without SQL statements.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	The timestamp of the last time the program, service program, or module was used. Contains the null value if the program, service program, or module has never been used.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the program, service program, or module was used since the last time the usage statistics were reset. If the program, service program, or module has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset. Contains the null value if the statistics have never been reset.
SYSTEM_PROGRAM_NAME	SYS_NAME	CHAR(10)	System name of the program, service program, or module.
SYSTEM_PROGRAM_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the program, service program, or module.
IASP_NUMBER	IASPNUMBER	INTEGER	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
SYSTEM_TIME_SENSITIVE	SYSTIME	VARCHAR(3) Nullable	Specifies whether the CURRENT TEMPORAL SYSTEM_TIME special register affects static and dynamic SQL statements in the program. YES Any references to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. NO Any references to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. Contains the null value, which is treated like NO, if the program was compiled prior to 7.3, or if the program is an external routine without SQL statements.

SYSPROGRAMSTMTSTAT

The SYSPROGRAMSTMTSTAT view contains one row for each embedded SQL statement in a program, module, or service program.

The following table describes the columns in the SYSPROGRAMSTMTSTAT view:

Table 205. SYSPROGRAMSTMTSTAT view

Column Name	System Column Name	Data Type	Description
PROGRAM_SCHEMA	COLLID	VARCHAR(128)	Name of the schema.
PROGRAM_NAME	NAME	VARCHAR(128)	Name of the program, service program, or module. For an SQL procedure, function, or trigger, this is the SQL object name.

Table 205. SYSPROGRAMSTMTSTAT view (continued)

Column Name	System Column Name	Data Type	Description
PROGRAM_TYPE	PGMTYPE	VARCHAR(128)	Type of the object : *PGM The object is a program. *MODULE The object is a module. *SRVPGM The object is a service program.
MODULE_NAME	MODNAME	VARCHAR(10) Nullable	Module name for ILE program or service program. Contains the null value if this is not an ILE program or service program.
STATEMENT_NUMBER	STMTNBR	INTEGER	Statement number in program.
NUMBER_TIMES_EXECUTED	NBREXEC	INTEGER	Number of times this statement has been executed. This value is not maintained for CALL, SET, or VALUES INTO statements.
ROWS_AFFECTED	ROWCNT	INTEGER	Total rows fetched, updated, inserted, or deleted for all executions of the statement. Contains 0 if the statement is not a FETCH, SET, VALUES INTO, UPDATE, INSERT, DELETE, or MERGE. Will contain 0 for a SET or VALUES INTO statement that is not implemented using a cursor.
NUMBER_HOST_VARIABLES	NBRHV	INTEGER	Total number of host variables specified in the statement. This includes input and output host variables.
NUMBER_INPUT_HOST_VARIABLES	NBRIHV	INTEGER	Number of input host variables specified in the statement.
WITH_HOLD	WITHHOLD	CHAR(3) Nullable	Specifies the WITH HOLD option for statement: YES WITH HOLD clause specified. Contains the null value if the clause was not specified.
FETCH_ONLY	FETCHONLY	CHAR(3) Nullable	Specifies the FOR READ ONLY option for statement: YES FOR READ ONLY clause specified. Contains the null value if the clause was not specified.
CONCURRENTACCESSRESOLUTION	CONCURRENT	CHAR(1) Nullable	Specifies the concurrent access resolution for the statement: W Wait for outcome U Use currently committed S Skip locked data Contains the null value if concurrent access was not specified at the statement level.
NUMBER_REBUILDS	NBRREBLD	INTEGER	Number of times QDT or access plan has been rebuilt.
ISOLATION	ISOLATION	CHAR(2) Nullable	Isolation option specification: RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NC No Commit (*NONE) Contains the null value if isolation level was not specified at the statement level.

Table 205. SYSPROGRAMSTMTSTAT view (continued)

Column Name	System Column Name	Data Type	Description
NUMBER_ROWS_TO_OPTIMIZE	OPTROWS	INTEGER Nullable	Number of rows specified on the OPTIMIZE FOR <i>n</i> ROWS clause. -1 means that the value *ALL was specified. Contains the null value if the clause was not specified.
NUMBER_ROWS_TO_FETCH	FETCHROWS	INTEGER Nullable	Number of rows specified on the FETCH FIRST <i>n</i> ROWS clause. Contains the null value if the clause was not specified.
LAST_QDT_REBUILD_REASON	QDTRBLD	CHAR(2) Nullable	Reason code for last QDT rebuild. This corresponds to column QVC22 in the STRDBMON outfile when QRID = 1000. Contains the null value if the statement does not use a QDT or has never had a QDT rebuilt.
STATEMENT_TEXT	STMTTEXT	DBCLOB(2M) CCSID(1200)	Text of the SQL statement.
SYSTEM_PROGRAM_NAME	SYS_NAME	CHAR(10)	System name of the program.
SYSTEM_PROGRAM_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema containing the program.
ACCESS_PLAN_LENGTH	AP_LENGTH	INTEGER	Number of bytes that are used for the QDT and access plan for the statement.
EARLIEST_POSSIBLE_RELEASE	MINRLS	VARCHAR(6)	The earliest IBM i release that supports this SQL statement (VxRxMx). ANY The statement is valid on any supported IBM i release. VxRxMx The statement is valid on IBM i VxRxMx release or later. Contains the null value if the earliest release is not known.
SQL_DB2_GROUP_LEVEL	SQL_LEVEL	INTEGER Nullable	The latest Db2 PTF Group level that SQL language syntax used in this statement is dependent on. Contains the null value if no SQL syntax in this statement was identified as being dependent on a Db2 PTF Group.
SERVICES_DB2_GROUP_LEVEL	SERV_LEVEL	INTEGER Nullable	The latest Db2 PTF Group level that a service referenced in this statement might be dependent on. This column contains a value if the SQL statement references an IBM i provided service or Db2 for i built-in function or built-in global variable. If the SQL statement includes unqualified references to objects whose names match IBM i provided services, this column considers the unqualified name as the IBM i service. Contains the null value if no built-in function, built-in global variable, or IBM i provided service in this statement was identified as being dependent on a Db2 PTF Group.

SYSREFCST

The SYSREFCST view contains one row for each foreign key in the SQL schema.

The following table describes the columns in the SYSREFCST view:

Table 206. SYSREFCST view

Column Name	System Column Name	Data Type	Description
CONSTRAINT_SCHEMA	CDBNAME	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.

Table 206. SYSREFCST view (continued)

Column Name	System Column Name	Data Type	Description
UNIQUE_CONSTRAINT_SCHEMA	UNQDBNAME	VARCHAR(128) Nullable	Name of the SQL schema containing the unique constraint referenced by the referential constraint. Contains the null value if the unique constraint does not exist. This is usually caused by restoring the table without its parent table.
UNIQUE_CONSTRAINT_NAME	UNQNAME	VARCHAR(128) Nullable	Name of the unique constraint referenced by the referential constraint. Contains the null value if the unique constraint does not exist. This is usually caused by restoring the table without its parent table.
MATCH_OPTION	MATCH	VARCHAR(7)	Match option. Will always be NONE.
UPDATE_RULE	UPDATE	VARCHAR(11)	Update Rule. <ul style="list-style-type: none">• NO ACTION• RESTRICT
DELETE_RULE	DELETE	VARCHAR(11)	Delete Rule <ul style="list-style-type: none">• NO ACTION• CASCADE• SET NULL• SET DEFAULT• RESTRICT
COLUMN_COUNT	COLCOUNT	INTEGER	Number of columns in the foreign key.
SYSTEM_CONSTRAINT_SCHEMA	SYS_CDNAME	CHAR(10)	Name of the system schema containing the constraint.
SYSTEM_UNIQUE_CONSTRAINT_SCHEMA	SYS_UDNAME	CHAR(10) Nullable	Name of the system schema containing the constraint. Contains the null value if the unique constraint does not exist. This is usually caused by restoring the table without its parent table.

SYSROUTINEAUTH

The SYSROUTINEAUTH view contains one row for every privilege granted on a routine. Note that this catalog view cannot be used to determine whether a user is authorized to a routine because the privilege to use a routine could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSROUTINEAUTH view:

Table 207. SYSROUTINEAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
ROUTINE_SCHEMA	RTNSCHEMA	VARCHAR(128)	Name of the schema
ROUTINE_NAME	RTNNNAME	VARCHAR(128)	Name of the routine
SPECIFIC_SCHEMA	SPECSHEMA	VARCHAR(128)	Specific name of the schema
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the routine. EXECUTE The privilege to execute the routine.

Table 207. SYSROUTINEAUTH view (continued)

Column Name	System Column Name	Data Type	Description
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.

SYSROUTINEDEP

The SYSROUTINEDEP view records the dependencies of routines.

The following table describes the columns in the SYSROUTINEDEP view:

Table 208. SYSROUTINEDEP view

Column name	System Column Name	Data Type	Description
SPECIFIC_SCHEMA	SPECSCHEMA	VARCHAR(128)	Schema name of the routine instance.
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine instance.
OBJECT_CATALOG	BCATALOG	VARCHAR(128) Nullable	Name of the relational database that contains the object. Contains the null value if the relational database name was not specified.
OBJECT_SCHEMA	BSCHHEMA	VARCHAR(128)	Name of the SQL schema that contains the object.
OBJECT_NAME	BNAME	VARCHAR(128)	Name of the object the routine is dependent on.
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object referenced in the routine: ALIAS The object is an alias. FUNCTION The object is a function. INDEX The object is an index. MATERIALIZED QUERY TABLE The object is a materialized query table. PROCEDURE The object is a procedure. SCHEMA The object is a schema. SEQUENCE The object is a sequence. TABLE The object is a table. If the object does not exist at the time the routine is created or the OBJECT_SCHEMA is *LIBL, TABLE may be returned even though the actual object used at run time may be an alias, materialized query table, or view. TYPE The object is a distinct type. VARIABLE The object is a variable. VIEW The object is a view.

Table 208. SYSROUTINEDEP view (continued)

Column name	System Column Name	Data Type	Description
PARM_SIGNATURE	SIGNATURE	BLOB(3M)	This column identifies the routine signature.
		Nullable	Contains the null value if the object is not a routine.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number of the object. 0 indicates the system ASP.
NUMBER_OF_PARMS	NUMPARMS	SMALLINT	Identifies the number of parameters.
		Nullable	Contains the null value if the object is not a routine.

SYSROUTINES

The SYSROUTINES table contains one row for each procedure created by the CREATE PROCEDURE statement and each function created by the CREATE FUNCTION statement.

The following table describes the columns in the SYSROUTINES table:

Table 209. SYSROUTINES table

Column Name	System Column Name	Data Type	Description
SPECIFIC_SCHEMA	SPECSCHEMA	VARCHAR(128)	Schema name of the routine instance.
SPECIFIC_NAME	SPECNAME	VARCHAR(128)	Specific name of the routine instance.
ROUTINE_SCHEMA	RTNSCHEMA	VARCHAR(128)	Name of the SQL schema (schema) that contains the routine.
ROUTINE_NAME	RTNNAME	VARCHAR(128)	Name of the routine.
ROUTINE_TYPE	RTNTYPE	VARCHAR(9)	Type of the routine. PROCEDURE This is a procedure. FUNCTION This is a function.
ROUTINE_CREATED	RTNCREATE	TIMESTAMP	Identifies the timestamp when the routine was created.
ROUTINE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the routine.
ROUTINE_BODY	BODY	VARCHAR(8)	The type of the routine body: EXTERNAL This is an external routine. SQL This is an SQL routine.
EXTERNAL_NAME	EXTNAME	VARCHAR(279) Nullable	This column identifies the external program name. <ul style="list-style-type: none">• For SQL functions or ILE service programs, the external program name is <i>schema-name/service-program-name(entry-point-name)</i>.• For REXX, the external program name is <i>schema-name/source-file-name(member-name)</i>.• For Java programs, the external program name is an optional jar-id followed by a <i>fully-qualified-class-name/method-name</i> or <i>fully-qualified-class-name.method-name</i>.• For all other languages, the external program name is <i>schema-name/program-name</i>. Contains the null value if this is a system-generated function.

Table 209. SYSROUTINES table (continued)

Column Name	System Column Name	Data Type	Description
EXTERNAL_LANGUAGE	LANGUAGE	VARCHAR(8) Nullable	If this is an external routine, this column identifies the external program's language. C The external program is written in C. C++ The external program is written in C++. CL The external program is written in CL. COBOL The external program is written in COBOL. COBOLLE The external program is written in ILE COBOL. FORTRAN The external program is written in FORTRAN. JAVA The external program is written in JAVA. PLI The external program is written in PL/I. REXX The external program is a REXX procedure. RPG The external program is written in RPG. RPGLE The external program is written in ILE RPG. Contains the null value if this is not an external routine.
PARAMETER_STYLE	PARM_STYLE	VARCHAR(7) Nullable	If this is an external routine, this column identifies the parameter style (calling convention). DB2GNRL This is the DB2GENERAL calling convention. DB2SQL This is the DB2SQL calling convention. GENERAL This is the GENERAL calling convention. JAVA This is the JAVA calling convention. NULLS This is the GENERAL WITH NULLS calling convention. SQL This is the SQL standard calling convention. Contains the null value if this is not an external routine.
IS_DETERMINISTIC	DETERMINE	VARCHAR(3)	This column identifies whether the routine is deterministic. That is, whether a call to the routine with the same arguments will always return the same result. NO The routine is not deterministic. YES The routine is global deterministic. STM The routine is statement deterministic.

Table 209. SYSROUTINES table (continued)

Column Name	System Column Name	Data Type	Description
SQL_DATA_ACCESS	DATAACCESS	VARCHAR(8) Nullable	This column identifies whether a routine contains SQL and whether it reads or modifies data. NONE The routine does not contain any SQL statements. CONTAINS The routine contains SQL statements. READS The routine possibly reads data from a table or view. MODIFIES The routine possibly modifies data in a table or view or issues SQL DDL statements.
SQL_PATH	SQL_PATH	VARCHAR(3483) Nullable	If this is an SQL routine, this column identifies the path. Contains the null value if this is not an SQL routine.
PARM_SIGNATURE	SIGNATURE	VARCHAR(16000)	This column identifies the routine signature.
NUMBER_OF_RESULTS	NUMRESULTS	SMALLINT	Identifies the number of results.
MAX_DYNAMIC_RESULT_SETS	RESULTS	SMALLINT	Identifies the maximum number of result sets returned. 0 indicates that there are no result sets.
IN_PARMS	IN_PARMS	SMALLINT	Identifies the number of input parameters. 0 indicates that there are no input parameters.
OUT_PARMS	OUT_PARMS	SMALLINT	Identifies the number of output parameters. 0 indicates that there are no output parameters.
INOUT_PARMS	INOUT_PARM	SMALLINT	Identifies the number of input/output parameters. 0 indicates that there are no input/output parameters.
PARSE_TREE	PARSE_TREE	VARCHAR(1024) FOR BIT DATA	Identifies the parse tree of the CREATE FUNCTION or CREATE PROCEDURE statement. It is only used internally.
PARM_ARRAY	PARM_ARRAY	BLOB(4M)	If this is an external routine, this column identifies the parameter array built from the CREATE FUNCTION or CREATE PROCEDURE statement. It is only used internally.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
ROUTINE_DEFINITION	ROUTINEDEF	DBCLOB(2M) CCSID 13488 Nullable	If this is an SQL routine, this column contains the SQL routine body. If this is an obfuscated routine, the text starts with the WRAPPED keyword and is followed by the encoded form of the statement text. Contains the null value if this is not an SQL routine.
FUNCTION_ORIGIN	ORIGIN	CHAR(1)	Identifies the type of function. If this is a procedure, this column contains a blank. B This is a built-in function (defined by Db2 for i). E This is a user-defined function. U This is a user-defined function that is sourced on another function. S This is a system-generated function.

Table 209. SYSROUTINES table (continued)

Column Name	System Column Name	Data Type	Description
FUNCTION_TYPE	TYPE	CHAR(1)	Identifies the form of the function. If this is a procedure, this column contains a blank. S This is a scalar function. C This is a column function. T This is a table function.
EXTERNAL_ACTION	EXACTION	CHAR(1) Nullable	Identifies whether the invocation of the function has external effects. E This function has external side effects. N This function does not have any external side effects. Contains the null value if the routine is a procedure.
IS_NULL_CALL	NULL_CALL	VARCHAR(3) Nullable	Identifies whether the function needs to be called if an input parameter is the null value. NO This function need not be called if an input parameter is the null value. If this is a scalar function, the result of the function is implicitly null if any of the operands are null. If this is a table function, the result of the function is an empty table if any of the operands are the null value. YES This function must be called even if an input operand is null. Contains the null value if the routine is a procedure.
SCRATCH_PAD	SCRATCHPAD	INTEGER Nullable	Identifies whether the address of a static memory area (scratch pad) is passed to the function. 0 The function does not have a scratch pad. integer Indicates the size of the scratch pad passed to the function. Contains the null value if the routine is a procedure.
FINAL_CALL	FINAL_CALL	VARCHAR(3) Nullable	Indicates whether a final call to the function should be made to allow the function to clean up its work areas (scratch pads). NO No final call is made. YES A final call to the function is made when the statement is complete. Contains the null value if the routine is a procedure.
PARALLELIZABLE	PARALLEL	VARCHAR(3) Nullable	Identifies whether the function can be run in parallel. NO The function must be synchronous. YES The function can be run in parallel. Contains the null value if the routine is a procedure.

Table 209. SYSROUTINES table (continued)

Column Name	System Column Name	Data Type	Description
DBINFO	DBINFO	VARCHAR(3) Nullable	Identifies whether information about the database is passed to the routine. NO No database information is passed to the routine. YES Information about the database is passed to the routine. Contains the null value if the routine is a procedure.
SOURCE_SPECIFIC_SCHEMA	SRCSCHHEMA	VARCHAR(128) Nullable	If this is sourced function and the source is user-defined, this column contains the name of the source schema. If this is a sourced function and the source is built-in, this column contains 'QSYS2'. Contains the null value if the routine is not a sourced function.
SOURCE_SPECIFIC_NAME	SRCTYPE	VARCHAR(128) Nullable	If this is sourced function and the source is user-defined, this column contains the specific name of the source function name. Contains the null value if the routine is not a sourced function.
IS_USER_DEFINED_CAST	CAST_FUNC	VARCHAR(3) Nullable	Identifies whether this function is a cast function created when a distinct type was created. NO This function is not a cast function. YES This function is a cast function. Contains the null value if the routine is a procedure.
CARDINALITY	CARD	BIGINT Nullable	Specifies the cardinality for a table function. Contains the null value if the function is not a table function or if cardinality was not specified.
FENCED	FENCED	VARCHAR(3) Nullable	Identifies whether a function is fenced. NO The function is not fenced. YES The function is fenced. Contains the null value if the routine is a procedure.
COMMIT_ON_RETURN	CMTONRET	VARCHAR(3) Nullable	This column identifies whether the procedure commits on a successful return from the procedure. NO A commit is not performed on successful return from the procedure. YES A commit is performed on successful return from the procedure. AUT Procedure will commit or rollback autonomously. Contains the null value if the routine is a function.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
NEW_SAVEPOINT_LEVEL	NEWSAVEPTL	VARCHAR(3) Nullable	This column identifies whether the routine starts a new savepoint level. NO A new savepoint level is not started. YES A new savepoint level is started.
LAST_ALTERED	ALTEREDTS	TIMESTAMP Nullable	Timestamp when routine was last altered. Contains null if the routine has never been altered.

Table 209. SYSROUTINES table (continued)

Column Name	System Column Name	Data Type	Description
DEBUG_MODE	DEBUG_MODE	CHAR(1)	Identifies whether the routine is debuggable. 0 The routine is not debuggable. 1 The routine is debuggable by the Unified Debugger. 2 The routine is debuggable by the system debugger. N The routine is disabled from being debugged by the Unified Debugger.
DEBUG_DATA	DEBUG_DATA	CLOB(1M) Nullable	Reserved. Contains the null value.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	If this is an SQL routine, identifies the DECFLOAT rounding mode. C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the routine is not an SQL routine.
ROUTINE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Contains the label for a routine. Contains the null value if a label does not exist.
SECURE	SECURE	CHAR(1)	Indicates whether the routine is considered secure for row access control and column access control. N The routine is not considered secure for row access control and column access control. Y The routine is considered secure for row access control and column access control.
ROUTINE_ENVIRONMENT	RTN_ENV	BLOB(16M) Nullable	Contains internal environment information for a routine defined with default expressions. Contains the null value if this is a procedure or function with no default expressions.
ROUTINE_DEFAULT_QDT	RTNDFTQDT	BLOB(1M) Nullable	Contains internal structure for a routine defined with default expressions. Contains the null value if this is a procedure or function with no default expressions.
ROUTINE_BIND_OPTION	BINDOPT	DBCLOB(5000) CCSID 1200 Nullable	The additional bind options used when creating this routine. Contains the null value if no explicit bind options were specified.

SYSSCHEMAAUTH

The SYSSCHEMAAUTH view contains one row for every privilege granted on a schema. Note that this catalog view cannot be used to determine whether a user is authorized to a schema because the privilege to use a schema could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSSCHEMAAUTH view:

Table 210. SYSSCHEMAAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
SCHEMA_NAME	NAME	VARCHAR(128)	Name of the schema
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: CREATEIN The privilege to create objects in the schema. USAGE The privilege to use the schema.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_SCHEMA_NAME	SYS_NAME	CHAR(10)	System name of the schema

SYSSCHEMAS

The SYSSCHEMAS view contains one row for every schema in the relational database.

For information related to a single schema, a query that uses table function OBJECT_STATISTICS will perform much better than querying SYSSCHEMAS. For example:

```
SELECT *
  FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST      ','LIB      ')) AS A
```

The following table describes the columns in the SYSSCHEMAS view:

Table 211. SYSSCHEMAS view

Column Name	System Column Name	Data Type	Description
SCHEMA_NAME	NAME	VARCHAR(128)	Name of the SQL schema.
SCHEMA_OWNER	OWNER	VARCHAR(128)	Owner of the schema.
SCHEMA_CREATOR	CREATOR	VARCHAR(128)	Name of the user that created the schema.
CREATION_TIMESTAMP	TIMESTAMP	TIMESTAMP	Timestamp when the schema was created.
SCHEMA_SIZE	SIZE	DECIMAL(15,0)	Size of the schema (in bytes).
SCHEMA_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement. Contains the null value if the schema has no text.
SYSTEM_SCHEMA_NAME	SYS_NAME	CHAR(10)	System schema name.

Table 211. SYSSCHEMAS view (continued)

Column Name	System Column Name	Data Type	Description
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

SYSSEQUENCEAUTH

The SYSSEQUENCEAUTH view contains one row for every privilege granted on a sequence. Note that this catalog view cannot be used to determine whether a user is authorized to a sequence because the privilege to use a sequence could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSSEQUENCEAUTH view:

Table 212. SYSSEQUENCEAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
SEQUENCE_SCHEMA	SEQSCHEMA	VARCHAR(128)	Name of the schema
SEQUENCE_NAME	SEQNAME	VARCHAR(128)	Name of the sequence
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the sequence. USAGE The privilege to use the sequence.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_SEQ_SCHEMA	SYSSSCHEMA	CHAR(10)	System name of the schema
SYSTEM_SEQ_NAME	SYSSNAME	CHAR(10)	System name of the sequence

SYSSEQUENCES

The SYSSEQUENCES view contains one row for every sequence object in the SQL schema.

The following table describes the columns in the SYSSEQUENCES view:

Table 213. SYSSEQUENCES view

Column name	System Column Name	Data Type	Description
SEQUENCE_SCHEMA	SEQSCHEMA	VARCHAR(128)	The name of the SQL schema containing the sequence.
SEQUENCE_NAME	SEQNAME	VARCHAR(128)	Name of the sequence.
MAXIMUM_VALUE	MAXVALUE	DECIMAL(63,0)	Maximum value of the sequence.
MINIMUM_VALUE	MINVALUE	DECIMAL(63,0)	Minimum value of the sequence.
INCREMENT	INCREMENT	INTEGER	Increment value of the sequence.

Table 213. SYSSEQUENCES view (continued)

Column name	System Column Name	Data Type	Description
CYCLE_OPTION	CYCLE	VARCHAR(3)	<p>Identifies whether the sequence values will continue to be generated after the minimum or maximum value has been reached.</p> <p>NO Values will not continue to be generated.</p> <p>YES Values will continue to be generated.</p>
CACHE	CACHE	INTEGER	Specifies the number of sequence values that may be preallocated for faster access. Zero indicates that the values will not be preallocated.
ORDER	ORDER	VARCHAR(3)	<p>Specifies whether the sequence values must be generated in order of the request.</p> <p>NO Values do not need to be generated in order of the request.</p> <p>YES Values must be generated in order of the request.</p>
DATA_TYPE	DATA_TYPE	VARCHAR(128)	Type of sequence:
			BIGINT Big number
			INTEGER Large number
			SMALLINT Small number
			DECIMAL Packed decimal
			NUMERIC Zoned decimal
			DISTINCT Distinct type
NUMERIC_PRECISION	PRECISION	INTEGER	The precision of all numeric columns.
USER_DEFINED_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128)	The name of the schema if this is a distinct type.
		Nullable	Contains the null value if the sequence is not a distinct type.
USER_DEFINED_TYPE_NAME	TYPENAME	VARCHAR(128)	The name of the distinct type.
		Nullable	Contains the null value if the sequence is not a distinct type.
START	START	DECIMAL(63,0)	Starting value of the sequence.
MAXASSIGNEDVAL	MAXASNVAL	DECIMAL(63,0)	Last possible assigned sequence value. This value includes any values that were cached, but not used.
		Nullable	Contains the null value when the sequence is created. Is not null after the first value is assigned.
SEQUENCE_DEFINER	DEFINER	VARCHAR(128)	The authorization ID under which the sequence was created.
SEQUENCE_CREATED	CREATEDTS	TIMESTAMP	Timestamp when the sequence was created.
LAST_ALTERED_TIMESTAMP	ALTEREDTS	TIMESTAMP	Timestamp when the sequence was last altered.
SEQUENCE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200	A character string supplied with the LABEL statement (sequence text).
		Nullable	Contains the null value if the sequence has no sequence text.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200	A character string supplied with the COMMENT statement.
		Nullable	Contains the null value if there is no long comment.
SYSTEM_SEQ_SCHEMA	SYSSSCHEMA	CHAR(10)	The system name of the schema

Table 213. SYSSEQUENCES view (continued)

Column name	System Column Name	Data Type	Description
SYSTEM_SEQ_NAME	SYSSNAME	CHAR(10)	The system name of the sequence
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

SYSTABAUTH

The SYSTABAUTH view contains one row for every privilege granted on a table or view. Note that this catalog view cannot be used to determine whether a user is authorized to a table or view because the privilege to use a table or view could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSTABAUTH view:

Table 214. SYSTABAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Name of the schema
TABLE_NAME	NAME	VARCHAR(128)	Name of the table
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the table. DELETE The privilege to delete rows from the table. INDEX The privilege to create an index on the table. INSERT The privilege to insert rows into the table. REFERENCES The privilege to reference the table in a referential constraint. SELECT The privilege to select rows from the table. UPDATE The privilege to update the table.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the schema
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table or view

SYSTABLEDEP

The SYSTABLEDEP view records the dependencies of materialized query tables.

The following table describes the columns in the SYSTABLEDEP view:

Table 215. SYSTABLEDEP view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table, view or alias
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table, view or alias. This is the SQL table, view or alias name if it exists; otherwise, it is the system table, view or alias name.
OBJECT_SCHEMA	BSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the object.
OBJECT_NAME	BNAME	VARCHAR(128)	Name of the object the materialized query table is dependent on.
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object referenced in the materialized query table: FUNCTION The object is a function. TABLE The object is a table. TYPE The object is a distinct type. VIEW The object is a view.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number of the object. 0 indicates the system ASP.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
PARM_SIGNATURE	SIGNATURE	BLOB(3M) Nullable	This column identifies the routine signature. Contains the null value if the object is not a routine.

SYSTABLEINDEXSTAT

The SYSTABLEINDEXSTAT view contains one row for every index that has at least one partition or member built over a table. If the index is over more than one partition or member, the statistics include all those partitions and members. If the table is a distributed table, the partitions that reside on other database nodes are not included. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSTABLEINDEXSTAT view:

Table 216. SYSTABLEINDEXSTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
NUMBER_PARTITIONS	NBRPARTS	INTEGER	Number of partitions or members of the table.
NUMBER DISTRIBUTED PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
INDEX_SCHEMA	INDSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the index, logical file, or constraint.

Table 216. SYSTABLEINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
INDEX_NAME	INDNAME	VARCHAR(128)	Name of the index, logical file, or constraint.
INDEX_TYPE	INDTYPE	VARCHAR(11)	The type of the index: INDEX The index is an SQL index. LOGICAL The index is part of a logical file. PRIMARY KEY The index is a primary key constraint. UNIQUE The index is a unique constraint. REFERENTIAL The index is a foreign key constraint.
NUMBER_KEY_COLUMNS	INDKEYS	BIGINT	Number of columns that define the index key.
COLUMN_NAMES	COLNAMES	VARCHAR(1024)	A comma separated list of column names that define the index key. If the length of all the column names exceeds 1024, '...' is returned at the end of the column value.
NUMBER_LEAF_PAGES	NLEAF	BIGINT	Not applicable for Db2 for i. Will always be -1.
NUMBER_LEVELS	NLEVELS	SMALLINT	Not applicable for Db2 for i. Will always be -1.
FIRSTKEYCARD	KEYCARD1	BIGINT	The total number of distinct first key values for all index partitions. If the index is an encoded vector index, this is the total number of unique values for the entire index key.
FIRST2KEYCARD	KEYCARD2	BIGINT	The total number of distinct keys using the first two columns for all index partitions. If the index is an encoded vector index, -1 is returned.
FIRST3KEYCARD	KEYCARD3	BIGINT	The total number of distinct keys using the first three columns for all index partitions. If the index is an encoded vector index, -1 is returned.
FIRST4KEYCARD	KEYCARD4	BIGINT	The total number of distinct keys using the first four columns for all index partitions. If the index is an encoded vector index, -1 is returned.
FULLKEYCARD	KEYCARDF	BIGINT	The total number of distinct full key values for all index partitions. If the index has more than 4 key columns or is an encoded vector index, -1 is returned.
CLUSTERRATIO	CLSRATIO	SMALLINT	Not applicable for Db2 for i. Will always be -1.
CLUSTERFACTOR	CLSFATOR	DOUBLE	Not applicable for Db2 for i. Will always be -1.
SEQUENTIAL_PAGES	SEQPAGES	BIGINT	Not applicable for Db2 for i. Will always be -1.
DENSITY	DENSITY	INTEGER	Not applicable for Db2 for i. Will always be -1.
PAGE_FETCH_PAIRS	FETCHPAIRS	VARCHAR(520)	Not applicable for Db2 for i. Will always be -1.
NUMBER_KEYS	NUMRIDS	BIGINT	The total number of keys for all index partitions. If the index is invalid or is an encoded vector index, -1 is returned.
NUMRIDS_DELETED	NUMRIDSDLT	BIGINT	Not applicable for Db2 for i. Will always be 0.
NUM_EMPTY_LEAFS	EMPTYLEAFS	BIGINT	Not applicable for Db2 for i. Will always be 0.
AVERAGE_RANDOM_FETCH_PAGES	AVGRNDFTCH	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_RANDOM_PAGES	AVGRNDPAGE	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_GAP	AVGSEQGAP	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_FETCH_GAP	AVGSEQFGAP	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_PAGES	AVGSEQPAGE	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVERAGE_SEQUENCE_FETCH_PAGES	AVGSEQFPAG	DOUBLE	Not applicable for Db2 for i. Will always be -1.
AVGPARTITION_CLUSTERRATIO	PCLSRATIO	SMALLINT	Not applicable for Db2 for i. Will always be -1.
AVGPARTITION_CLUSTERFACTOR	PCLSFATOR	DOUBLE	Not applicable for Db2 for i. Will always be -1.

Table 216. SYSTABLEINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
AVGPARTITION_PAGE_FETCH_PAIRS	PFETCHPAIR	VARCHAR(520)	Not applicable for Db2 for i. Will always be an empty string.
DATAPARTITION_CLUSTERFACTOR	DCLSFATOR	DOUBLE	A statistic measuring the "clustering" of the index keys with regard to data partitions. It is a number between 0 and 1, with 1 representing perfect clustering and 0 representing no clustering.
INDCARD	INDCARD	BIGINT	Number of keys in the index. If the index is invalid or is an encoded vector index, -1 is returned.
INDEX_VALID	VALID	CHAR(1)	An indication of whether any index is invalid and needs to be rebuilt: 0 At least one partition or member for the index is invalid. 1 All partitions or members for the index are valid. 2 The index was saved with STG(*FREE).
INDEX_HELD	HELD	CHAR(1)	An indication of whether a pending rebuild of the index is currently held by the user: 0 No rebuilds are pending or held for any partition or member of the index. 1 A pending rebuild for at least one partition or member for the index is held.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	Maximum timestamp when any partition or member of the index was created.
LAST_BUILD_TIMESTAMP	LASTBUILD	TIMESTAMP	Maximum timestamp when any partition or member of the index was last rebuilt.
LAST_QUERY_USE	LASTQRYUSE	TIMESTAMP Nullable	Maximum timestamp of the last time any partition or member of the index was used in a query since the last time the usage statistics were reset. If no partition or member of the index has ever been used in a query since the last time the usage statistics were reset, contains null.
LAST_STATISTICS_USE	LASTSTUSE	TIMESTAMP Nullable	Maximum timestamp of the last time any partition or member of the index was used by the optimizer for statistics since the last time the usage statistics were reset. If no partition or member of the index has ever been used for statistics since the last time the usage statistics were reset, contains null.
QUERY_USE_COUNT	QRYUSECNT	BIGINT	Total number of times any partition or member of the index was used in a query since the last time the usage statistics were reset. If no partition or member of the index has ever been used in a query since the last time the usage statistics were reset, contains 0.
QUERY_STATISTICS_COUNT	QRYSTCNT	BIGINT	Total number of times any partition or member of the index was used by the optimizer for statistics since the last time the usage statistics were reset. If no partition or member of the index has ever been used for statistics since the last time the usage statistics were reset, contains 0.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	Maximum timestamp of the last time any partition or member of the index was used directly by an application for native record I/O or SQL operations. If no partition or member of the index has ever been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	Maximum number of days any partition or member of the index was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If no partition or member of the index has ever been used since the last time the usage statistics were reset, contains 0.

Table 216. SYSTABLEINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	Maximum timestamp of the last time the usage statistics were reset for the index. For more information see the Change Object Description (CHGOBJD) command. If the index's last used timestamp has never been reset, contains null.
INDEX_SIZE	SIZE	BIGINT	Size (in bytes) of the data space index used by all partitions or members of the index.
ESTIMATED_BUILD_TIME	ESTBLDTIME	INTEGER	Maximum estimated time (in seconds) required to rebuild any partition or member of the index.
LAST_BUILD_TIME	LSTBLDTIME	INTEGER Nullable	Elapsed time (in seconds) the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_KEYS	LSTBLDKEYS	BIGINT Nullable	Number of keys the last time the index was built. Contains null if the last build information is not available.
LAST_BUILD_DEGREE	LSTBLDDEG	SMALLINT Nullable	Parallel degree the last time the index was built. Contains null if the last build information is not available.
DELAYED_MAINT_KEYS	DLYKEYS	INTEGER Nullable	Maximum number of keys that need to be inserted into the binary tree of any partition or member of a delayed maintenance index. If the index is not a delayed maintenance index, contains null.
SPARSE	SPARSE	CHAR(1)	Indicates whether the index contains keys for all the rows of its depended on table: 0 The index contains keys for all the rows of its depended on table. 1 The index is a select/omit logical file and does not contain keys for all the rows of its depended on table.
DERIVED_KEY	DERIVED	CHAR(1)	Indicates whether any key columns in the index are expressions: 0 No key columns of the index are expressions. 1 At least one key column is an expression. Currently, this is only possible in a DDS-created logical file or temporary index.
PARTITIONED	PARTITION	CHAR(1)	Indicates whether the index is partitioned or not partitioned: 0 An SQL index is not partitioned (spans multiple partitions). 1 The index is not built over a partitioned table or built over a partitioned table and is partitioned (does not span multiple partitions or members). 2 The index is a logical file built over multiple partitions or members.
ACCPTH_TYPE	ACCPHTYPE	CHAR(1)	Indicates the type of index: 0 The index is a maximum 1 terabyte (*MAX1TB) binary radix index. 1 The index is a maximum 4 gigabyte (*MAX4GB) binary radix index. 2 The index is an encoded vector index.

Table 216. SYSTABLEINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
UNIQUE	UNIQUE	CHAR(1)	Indicates whether an index is unique: 0 The index is a UNIQUE index. 1 The index is a UNIQUE WHERE NOT NULL index. 2 The index is a non-unique first-in-first-out (FIFO) index. 3 The index is a non-unique last-in-last-out (LIFO) index. 4 The index is a non-unique first-change-first-out (FCFO) index.
SRTSEQ_TYPE	SRTSEQ	CHAR(1)	Indicates whether the index uses a collating sequence: 0 The index does not use a collating table. 1 The index uses an alternate collating sequence (ALTSEQ). 2 The index uses a sort sequence (SRTSEQ).
LOGICAL_PAGE_SIZE	PAGE_SIZE	INTEGER Nullable	The logical page size of the index. If the index is an encoded vector index, contains null.
OVERFLOW_VALUES	OVERFLOW	INTEGER Nullable	Maximum number of distinct key values that have overflowed any partition or member of the encoded vector index. If the index is not an encoded vector index, contains null.
EVI_CODE_SIZE	CODE_SIZE	INTEGER Nullable	The size of the byte code of the encoded vector index. If the index is not an encoded vector index, contains null.
LOGICAL_READS	LGLREADS	BIGINT	Total number of logical read operations for any partition or member of the index since the last IPL.
PHYSICAL_READS	PHYREADS	BIGINT	Not applicable for Db2 for i. Will always be 0.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the index since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the index since the last IPL.
SEARCH_CONDITION	IXWHERECON	VARGRAPHIC(1024) CCSID 1200	If an index is sparse, the search condition of the index. If the length of the search condition exceeds 1024, '...' is returned at the end of the column value.
KEEP_IN_MEMORY	KEEPINMEM	CHAR(1)	Indicates whether the index should be kept in memory: 0 No memory preference. 1 The index should be kept in memory, if possible.
MEDIA_PREFERENCE	MEDIAPREF	SMALLINT	Indicates the media preference of the index: 0 No media preference. 255 The index should be allocated on Solid State Disk (SSD), if possible.
INCLUDE_EXPRESSION	IXINCEXPR	VARGRAPHIC(1024) CCSID 1200 Nullable	Index INCLUDE expression. Contains null if the index does not have an INCLUDE expression.

Table 216. SYSTABLEINDEXSTAT view (continued)

Column name	System Column Name	Data Type	Description
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.

SYSTABLES

The SYSTABLES view contains one row for every table, view or alias in the SQL schema, including the tables and views of the SQL catalog.

Additional table attributes and native file information, including program described files and join logical files, are available through the [QSYS2.SYSFILES](#) view.

The following table describes the columns in the SYSTABLES view:

Table 217. SYSTABLES view

Column name	System Column Name	Data Type	Description
TABLE_NAME	NAME	VARCHAR(128)	Name of the table, view or alias. This is the SQL table, view or alias name if it exists; otherwise, it is the system table, view or alias name.
TABLE_OWNER	CREATOR	VARCHAR(128)	Owner of the table, view or alias
TABLE_TYPE	TYPE	CHAR(1)	If the row describes a table, view, or alias: A Alias L Logical file M Materialized query table P Physical file T Table V View
COLUMN_COUNT	COLCOUNT	INTEGER	Number of columns in the table or view. Zero for an alias.
ROW_LENGTH	RECLENGTH ¹⁶⁵	INTEGER	Maximum length of any record in the table. Zero for an alias.
TABLE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200	A character string provided with the LABEL statement.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200	A character string supplied with the COMMENT statement. Nullable Contains the null value if there is no long comment.
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Name of the SQL schema that contains the table, view or alias
LAST_ALTERED_TIMESTAMP	ALTEREDTS	TIMESTAMP	Timestamp when the table was last altered or created.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name
FILE_TYPE	FILETYPE	CHAR(1)	File type D Data file or alias S Source file
BASE_TABLE_CATALOG	LOCATION	VARCHAR(18) Nullable	For an alias, this is the name of the relational database that contains the table or view the alias is based on. Contains the null value if the table is not an alias.

Table 217. SYSTABLES view (continued)

Column name	System Column Name	Data Type	Description
BASE_TABLE_SCHEMA	TBDBNAME	VARCHAR(128) Nullable	For an alias, this is the name of the SQL schema that contains the table or view the alias is based on. Contains the null value if the table is not an alias.
BASE_TABLE_NAME	TBNAME	VARCHAR(128) Nullable	For an alias, this is the name of the table or view the alias is based on. Contains the null value if the table is not an alias.
BASE_TABLE_MEMBER	TBMEMBER	VARCHAR(10) Nullable	For an alias, this is the name of the file member the alias is based on. Contains *FIRST if this is an alias, but a member name was not specified. Contains *LAST if the alias is based on the most recent member in the file. Contains the null value if the table is not an alias.
SYSTEM_TABLE	SYSTABLE	CHAR(1)	System table N The table is not a system table. Y The table is a system table.
SELECT OMIT	SELECTOMIT	CHAR(1)	Select/omit logical file D The table is a dynamic select/omit logical file. N The table is not a select/omit logical file. Y The table is a select/omit logical file.
IS_INSERTABLE_INTO	INSERTABLE	VARCHAR(3)	Identifies whether an INSERT is allowed on the table. NO An INSERT is not allowed on this table. YES An INSERT is allowed on this table.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
ENABLED	ENABLED	VARCHAR(3) Nullable	Indicates whether the materialized query table is enabled for optimization: NO The materialized query table is not enabled for optimization. YES The materialized query table is enabled for optimization. Contains the null value if the table is not a materialized query table.
MAINTENANCE	MAINTAIN	VARCHAR(6) Nullable	Indicates whether the materialized query table is user or system maintained: USER The materialized query table is user maintained. Contains the null value if the table is not a materialized query table.
REFRESH	REFRESH	VARCHAR(9) Nullable	Indicates the materialized query table REFRESH option: DEFERRED The materialized query table is REFRESH DEFERRED. Contains the null value if the table is not a materialized query table.

Table 217. SYSTABLES view (continued)

Column name	System Column Name	Data Type	Description
REFRESH_TIME	REFRESHHTS	TIMESTAMP Nullable	Indicates the timestamp of the last materialized query table REFRESH: Contains the null value if the table is not a materialized query table or if the table has never been refreshed.
MQT_DEFINITION	MQTDEF	DBCLOB(2M) CCSID 13488 Nullable	Indicates the query expression of the materialized query table: Contains the null value if the table is not a materialized query table.
ISOLATION	ISOLATION	CHAR(2) Nullable	Indicates the isolation level used for the <i>select-statement</i> when refreshing the materialized query table: RR Repeatable Read (*RR) RS Read Stability (*ALL) CS Cursor Stability (*CS) UR Uncommitted Read (*CHG) NC No Commit (*NONE) Contains the null value if the table is not a materialized query table.
PARTITION_TABLE	PART_TABLE	VARCHAR(11)	Indicates whether the table is a partitioned table: DISTRIBUTED The table is a distributed table. NO The table is not a partitioned table. YES The table is a partitioned table.
TABLE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the table.
MQT_RESTORE_DEFERRED	MQTRSTDFFR	CHAR(1)	If the table is a materialized query table: Y The MQT is deferred as the result of a restore. N The MQT is not deferred. Contains the null value if the table is not a materialized query table.
ROUNDING_MODE	DECFLTRND	CHAR(1)	Indicates the DECFLOAT rounding mode of the materialized query table or view: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the table is not a view or MQT, or if the materialized query table or view does not have an expression that references a DECFLOAT column, function, or constant.

Table 217. SYSTABLES view (continued)

Column name	System Column Name	Data Type	Description
CONTROL	CONTROL	CHAR(1)	Indicates whether the table is enforced by row or column access control: blank No access control enforcement. R The table is enforced by row access control. C The table is enforced by column access control. B The table is enforced by both row and column access control.
TEMPORAL_TYPE	TEMPORALITY	CHAR(1)	Indicates the type of temporal table: H History table for a system-period temporal table N Not a temporal table S System-period temporal table

SYSTABLESTAT

The SYSTABLESTAT view contains one row for every table that has at least one partition or member. If the table has more than one partition or member, the statistics include all partitions and members. If the table is a distributed table, the partitions that reside on other database nodes are not included. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSTABLESTAT view:

Table 218. SYSTABLESTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.
NUMBER_PARTITIONS	NBRPARTS	INTEGER	Number of partitions or members of the table.
NUMBER_DISTRIBUTED_PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.
NUMBER_ROWS	CARD	BIGINT	Number of valid rows in all partitions or members of the table.
NUMBER_ROW_PAGES	NPAGES	BIGINT	Number of 64K pages in all partitions or members of the table.
NUMBER_PAGES	FPAGES	BIGINT	Same as NUMBER_ROW_PAGES.

¹⁶⁵ The length is the number of bytes passed in database buffers, not the internal storage length.

Table 218. SYSTABLESTAT view (continued)

Column name	System Column Name	Data Type	Description
OVERFLOW	OVERFLOW	BIGINT	The estimated number of rows that have overflowed to variable length segments. If the table does not contain variable length or LOB columns, contains 0.
CLUSTERED	CLUSTERED	CHAR(1) Nullable	Not applicable for Db2 for i. Will always be null.
ACTIVE_BLOCKS	ACTBLOCKS	BIGINT	Not applicable for Db2 for i. Will always be -1.
AVGCOMPRESSEDROWSIZE	ACROWSIZE	BIGINT	Not applicable for Db2 for i. Will always be -1.
AVGROWCOMPRESSIONRATIO	ACROWRATIO	REAL	Not applicable for Db2 for i. Will always be -1.
AVGROWSIZE	AVGROWSIZE	BIGINT	Average length (in bytes) of a row in this table. If the table has variable length or LOB columns, contains -1.
PCTROWSCOMPRESSED	PCTCROWS	REAL	Not applicable for Db2 for i. Will always be -1.
PCTPAGESAVED	PCTPGSAVED	SMALLINT	Not applicable for Db2 for i. Will always be -1.
NUMBER_DELETED_ROWS	DELETED	BIGINT	Number of deleted rows in all partitions or members of the table.
DATA_SIZE	SIZE	BIGINT	Total size (in bytes) of the data spaces in all partitions or members of the table.
VARIABLE_LENGTH_SIZE	VLSIZE	BIGINT	Size (in bytes) of the variable-length data space segments in all partitions or members of the table.
VARIABLE_LENGTH_SEGMENTS	VLSEGMENTS	BIGINT	The number of variable-length data space segments in all partitions or members of the table.
FIXED_LENGTH_EXTENTS	FLEXTENTS	BIGINT	Not applicable for Db2 for i. Will always be -1.
VARIABLE_LENGTH_EXTENTS	VLEXTENTS	BIGINT	Not applicable for Db2 for i. Will always be -1.
COLUMN_STATS_SIZE	CSTATSSIZE	BIGINT	Size (in bytes) of the column statistics in all partitions or members of the table.
MAINTAINED_TEMPORARY_INDEX_SIZE	MTISIZE	BIGINT	Size (in bytes) of all maintained temporary indexes over any partitions or members of the table.
NUMBER_DISTINCT_INDEXES	DISTINCTIX	INTEGER	The number of distinct indexes built over any partitions or members of the table. This does not include maintained temporary indexes.
OPEN_OPERATIONS	OPENS	BIGINT	Number of full opens of all partitions or members of the table since the last IPL.
CLOSE_OPERATIONS	CLOSES	BIGINT	Number of full closes of all partitions or members of the table since the last IPL.
INSERT_OPERATIONS	INSERTS	BIGINT	Number of insert operations of all partitions or members of the table since the last IPL.
BLOCKED_INSERT_OPERATIONS	BLKIOPS	BIGINT	Number of blocked insert operations for the partition or member since the last IPL.
BLOCKED_INSERT_ROWS	BLKIROW	BIGINT	Number of rows inserted with blocked insert operations for the partition or member since the last IPL.
UPDATE_OPERATIONS	UPDATES	BIGINT	Number of update operations of all partitions or members of the table since the last IPL.
DELETE_OPERATIONS	DELETES	BIGINT	Number of delete operations of all partitions or members of the table since the last IPL.
CLEAR_OPERATIONS	DSCLEARS	BIGINT	Number of clear operations (CLRPFM operations) of all partitions or members of the table since the last IPL.
COPY_OPERATIONS	DSCOPIES	BIGINT	Number of data space copy operations (certain CPYxxx operations) of all partitions or members of the table since the last IPL.
REORGANIZE_OPERATIONS	DSREORGs	BIGINT	Number of data space reorganize operations (non-interruptible RGZPFM operations) of all partitions or members of the table since the last IPL.

Table 218. SYSTABLESTAT view (continued)

Column name	System Column Name	Data Type	Description
INDEX_BUILDS	DSINXBLDS	BIGINT	Number of creates or rebuilds of indexes that reference any partition or member of the table since the last IPL. This does not include maintained temporary indexes.
LOGICAL_READS	LGLREADS	BIGINT	Number of logical read operations of all partitions or members of the table since the last IPL.
PHYSICAL_READS	PHYREADS	BIGINT	Number of physical read operations of all partitions or members of the table since the last IPL.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations of all partitions or members of the table since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations of all partitions or members of the table since the last IPL.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP	Maximum timestamp of the last change that occurred to any partition or member of the table.
LAST_SAVE_TIMESTAMP	LASTSAVE	TIMESTAMP Nullable	Minimum timestamp of the last save of any partition or member of the table. If no partition or member has been saved, contains null.
LAST_RESTORE_TIMESTAMP	LASTRST	TIMESTAMP Nullable	Maximum timestamp of the last restore any partition or member of the table. If no partition or member has been restored, contains null.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	Maximum timestamp of the last time any partition or member was used directly by an application for native record I/O or SQL operations. If no partition or member has ever been used, contains null.
DAYS_USED_COUNT	DAYSUSED	INTEGER	Maximum number of days any partition or member was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If no partition or member has been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	Maximum timestamp of the last time the usage statistics were reset for the table. For more information see the Change Object Description (CHGOBJD) command. If no partition or member's last used timestamp has ever been reset, contains null.
NUMBER_PARTITIONING_KEYS	NBRPKEYS	INTEGER Nullable	The number of partitioning keys. If the table is not partitioned, contains null.
PARTITIONING_KEYS	PARTKEYS	VARCHAR(2880) Nullable	The list of partitioning keys. If the table is not partitioned, contains null.
VOLATILE	VOLATILE	CHAR(1)	Indicates whether the table is volatile. 0 Table is not volatile. 1 Table is volatile.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.

SYSTRIGCOL

The SYSTRIGCOL view contains one row for each column either implicitly or explicitly referenced in the WHEN clause or the triggered SQL statements of a trigger.

The following table describes the columns in the SYSTRIGCOL view:

Table 219. SYSTRIGCOL view

Column Name	System Column Name	Data Type	Description
TRIGGER_SCHEMA	TRIGSCHEMA	VARCHAR(128)	Name of the schema containing the trigger.
TRIGGER_NAME	TRIGNAME	VARCHAR(128)	Name of the trigger.
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the schema containing the table or view that contains the column that is referenced in the trigger.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table or view that contains the column that is referenced in the trigger.
COLUMN_NAME	TABCOLUMN	VARCHAR(128)	Name of the column that is referenced in the trigger.
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object that contains the column referenced in the trigger:
			FUNCTION The object is a function.
			MATERIALIZED QUERY TABLE The object is a materialized query table.
			TABLE The object is a table.
			VIEW The object is a view.
SYSTEM_TRIGGER_SCHEMA	SYS_TDNAME	CHAR(10)	System schema name.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10) Nullable	System schema name of the table or view that contains the column that is referenced in the trigger. Contains the null value if the referenced table does not exist or if the referenced object is a table function.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10) Nullable	System table name of the table or view that contains the column that is referenced in the trigger. Contains the null value if the referenced table does not exist or if the referenced object is a table function.

SYSTRIGDEP

The SYSTRIGDEP view contains one row for each object referenced in the WHEN clause or the triggered SQL statements of a trigger.

The following table describes the columns in the SYSTRIGDEP view:

Table 220. SYSTRIGDEP view

Column Name	System Column Name	Data Type	Description
TRIGGER_SCHEMA	TRIGSCHEMA	VARCHAR(128)	Name of the schema containing the trigger.
TRIGGER_NAME	TRIGNAME	VARCHAR(128)	Name of the trigger.
OBJECT_SCHEMA	BSSCHEMA	VARCHAR(128)	Name of the schema containing the object referenced in the trigger.
OBJECT_NAME	BNAME	VARCHAR(128)	Name of the object referenced in the trigger.

Table 220. SYSTRIGDEP view (continued)

Column Name	System Column Name	Data Type	Description
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object referenced in the trigger: ALIAS The object is an alias. FUNCTION The object is a function. INDEX The object is an index. MATERIALIZED QUERY TABLE The object is a materialized query table. PACKAGE The object is a package. PROCEDURE The object is a procedure. SCHEMA The object is a schema. SEQUENCE The object is a sequence. TABLE The object is a table. TYPE The object is a distinct type. VARIABLE The object is a variable. VIEW The object is a view.
PARM_SIGNATURE	SIGNATURE	BLOB(3M) Nullable	This column identifies the routine signature. Contains the null value if the object is not a routine.
SYSTEM_TRIGGER_SCHEMA	SYS_TDNAME	CHAR(10)	System schema name.
SYSTEM_OBJECT_SCHEMA	SYS_DNAME	CHAR(10) Nullable	System schema name of the object referenced in the trigger. Contains the null value if the referenced object does not exist or if the referenced object is not an alias, index, materialized query table, table, or view.
SYSTEM_OBJECT_NAME	SYS_ONAME	CHAR(10) Nullable	System object name of the object referenced in the trigger. Contains the null value if the referenced object does not exist or if the referenced object is not an alias, index, materialized query table, table, or view.

SYTRIGGERS

The SYTRIGGERS view contains one row for each trigger in an SQL schema.

The following table describes the columns in the SYTRIGGERS view:

Table 221. SYTRIGGERS view

Column Name	System Column Name	Data Type	Description
TRIGGER_SCHEMA	TRIGSCHEMA	VARCHAR(128)	Name of the schema containing the trigger.
TRIGGER_NAME	TRIGNAME	VARCHAR(128)	Name of the trigger.

Table 221. SYSTRIGGERS view (continued)

Column Name	System Column Name	Data Type	Description
EVENT_MANIPULATION	TRIGEVENT	VARCHAR(6)	<p>Indicates the event that causes the trigger to fire:</p> <p>DELETE Trigger fires on a DELETE.</p> <p>INSERT Trigger fires on a INSERT.</p> <p>UPDATE Trigger fires on a UPDATE.</p> <p>READ Trigger fires when a row is read. This is only valid for triggers created via the ADDPFTRG command.</p> <p>MULTI Trigger fires for multiple events. The EVENTUPDATE, EVENTDELETE, and EVENTINSERT columns define the events.</p>
EVENT_OBJECT_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the schema containing the subject table or view of the trigger.
EVENT_OBJECT_TABLE	TABNAME	VARCHAR(128)	Name of the subject table or view of the trigger.
ACTION_ORDER	ORDERSEQNO	INTEGER	The ordinal position of this trigger in the list of triggers for the table or view. This indicates the order in which the trigger will be fired.
ACTION_CONDITION	CONDITION	DBCLOB(2097152) CCSID 13488 Nullable	<p>Text of the WHEN clause for the trigger.</p> <p>Contains the null value if there is no WHEN clause or if this is an obfuscated trigger.</p>
ACTION_STATEMENT	TEXT	DBCLOB(2097152) CCSID 13488 Nullable	<p>Text of the SQL statements in the trigger action.</p> <p>If this is an obfuscated trigger, the text starts with the WRAPPED keyword and is followed by the encoded form of the statement text.</p> <p>Contains the null value if this is a trigger created via the ADDPFTRG command.</p>
ACTION_ORIENTATION	GRANULAR	VARCHAR(9)	<p>Indicates whether this is a ROW or STATEMENT trigger:</p> <p>ROW Trigger fires for each ROW.</p> <p>STATEMENT Trigger fires for each statement.</p>
ACTION_TIMING	TRIGTIME	VARCHAR(7)	<p>Indicates whether this is a BEFORE, AFTER, or INSTEAD OF trigger:</p> <p>BEFORE Trigger fires before the triggering event.</p> <p>AFTER Trigger fires after the triggering event.</p> <p>INSTEAD Trigger fires instead of the triggering event.</p>
TRIGGER_MODE	TRIGMODE	VARCHAR(6)	Indicates the firing mode for the trigger:
			<p>DB2SQL The trigger mode is DB2SQL.</p> <p>DB2ROW The trigger mode is DB2ROW.</p>
ACTION_REFERENCE_OLD_ROW	OLD_ROW	VARCHAR(128) Nullable	<p>Name of the OLD ROW correlation name.</p> <p>Contains the null value if an OLD ROW correlation name was not specified.</p>
ACTION_REFERENCE_NEW_ROW	NEW_ROW	VARCHAR(128) Nullable	<p>Name of the NEW ROW correlation name.</p> <p>Contains the null value if a NEW ROW correlation name was not specified.</p>
ACTION_REFERENCE_OLD_TABLE	OLD_TABLE	VARCHAR(128) Nullable	<p>Name of the OLD TABLE correlation name.</p> <p>Contains the null value if an OLD TABLE correlation name was not specified.</p>

Table 221. SYSTRIGGERS view (continued)

Column Name	System Column Name	Data Type	Description
ACTION_REFERENCE_NEW_TABLE	NEW_TABLE	VARCHAR(128)	Name of the NEW TABLE correlation name.
		Nullable	Contains the null value if a NEW TABLE correlation name was not specified.
SQL_PATH	SQL_PATH	VARCHAR(3483)	SQL path used when the trigger was created.
		Nullable	Contains the null value if the trigger was created via the ADDPFTRG command.
CREATED	CREATE_DTS	TIMESTAMP	Timestamp when the trigger was created.
TRIGGER_PROGRAM_NAME	TRIGPGM	VARCHAR(128)	Name of the trigger program.
TRIGGER_PROGRAM_LIBRARY	TRIGPGMLIB	VARCHAR(128)	System name of the schema containing the trigger program.
OPERATIVE	OPERATIVE	VARCHAR(1)	<p>Indicates whether the trigger is operative.</p> <p>A table or view that has a trigger that contains a reference to that same table or view in its <i>triggered-action</i> is self-referencing. If a self-referencing trigger is duplicated into another library, restored into another library, moved into another library, or renamed; the trigger is marked inoperative since the table references in the <i>triggered-action</i> are unchanged and still reference the original schema and table name.</p> <p>Y The trigger is operative.</p> <p>N The trigger is inoperative.</p>
ENABLED	ENABLED	VARCHAR(1)	<p>Indicates whether the trigger is enabled.</p> <p>Y The trigger is enabled.</p> <p>N The trigger is disabled.</p>
THREADSAFE	THDSAFE	VARCHAR(8)	<p>Indicates whether the trigger is thread safe.</p> <p>YES The trigger is thread safe.</p> <p>NO The trigger is not thread safe.</p> <p>UNKNOWN The thread safety of the trigger is unknown.</p>
MULTITHREADED_JOB_ACTION	MLTTHDACN	VARCHAR(8)	<p>Indicates the action to take when the trigger program is called in a multithreaded job.</p> <p>SYSVAL Use the QMLTTHDACN system value to determine the action to take.</p> <p>MSG Run the trigger program in a multithreaded job, but send a diagnostic message.</p> <p>NORUN Do not run the trigger program in a multithreaded job.</p> <p>RUN Run the trigger program in a multithreaded job.</p>
ALLOW_REPEAT_CHANGE	ALWREPCHG	VARCHAR(8)	<p>Indicates the condition under which an update event fires the trigger.</p> <p>YES The trigger allows repeated changes to the same row.</p> <p>NO The trigger does not allow repeated changes to the same row.</p>

Table 221. SYSTRIGGERS view (continued)

Column Name	System Column Name	Data Type	Description
TRIGGER_UPDATE_CONDITION	TRGUPDCND	CHAR(8) Nullable	Indicates whether an UPDATE trigger is always fired on an update event or only when a column value is actually changed. ALWAYS The trigger is always fired on an update event. CHANGE The trigger is only fired on an update event if a column value is actually changed. Contains the null value if the trigger is not an UPDATE trigger.
TRIGGER_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the trigger.
TRIGGER_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string provided with the LABEL statement. Contains the null value if there is no label.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 13488 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	The rounding mode for the trigger: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the trigger was created via the ADDPFTRG command.
SYSTEM_TRIGGER_SCHEMA	SYS_TDNAME	CHAR(10)	System schema name.
SYSTEM_EVENT_OBJECT_SCHEMA	SYS_DNAME	CHAR(10)	System schema name of the schema containing the subject table or view of the trigger.
SYSTEM_EVENT_OBJECT_TABLE	SYS_TNAME	CHAR(10)	System table name of the table or view that contains the subject table or view of the trigger.
SECURE	SECURE	CHAR(1)	Indicates whether the trigger is considered secure for row access control and column access control. N The trigger is not considered secure for row access control and column access control. Y The trigger is considered secure for row access control and column access control.
LAST_ALTERED	ALTEREDTS	TIMESTAMP Nullable	Timestamp when the trigger was last altered. Contains the null value if the trigger has never been altered.
EVENTUPDATE	EVENT_U	CHAR(1)	Indicates whether an update event fires this trigger. Y Yes N No

Table 221. SYSTRIGGERS view (continued)

Column Name	System Column Name	Data Type	Description
EVENTINSERT	EVENT_I	CHAR(1)	Indicates whether an insert event fires this trigger. Y Yes N No
EVENTDELETE	EVENT_D	CHAR(1)	Indicates whether a delete event fires this trigger. Y Yes N No
MIRRORED	MIRRORED	CHAR(1)	Always N.
TRIGGER_BIND_OPTION	BINDOPT	DBCLOB(5000) CCSID 1200 Nullable	The additional bind options used when creating this trigger. Contains the null value if no explicit bind options were specified.

SYSTRIGUPD

The SYSTRIGUPD view contains one row for each column identified in the UPDATE column list, if any.

The following table describes the columns in the SYSTRIGUPD view:

Table 222. SYSTRIGUPD view

Column Name	System Column Name	Data Type	Description
TRIGGER_SCHEMA	TRIGSCHEMA	VARCHAR(128)	Name of the schema containing the trigger.
TRIGGER_NAME	TRIGNAME	VARCHAR(128)	Name of the trigger.
EVENT_OBJECT_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the schema containing the subject table of the trigger.
EVENT_OBJECT_TABLE	TABNAME	VARCHAR(128)	Name of the subject table of the trigger.
TRIGGERED_UPDATE_COLUMNS	TABCOLUMN	VARCHAR(128)	Name of a column specified in the UPDATE column list of the trigger.
SYSTEM_TRIGGER_SCHEMA	SYS_TDNAME	CHAR(10)	System schema name.
SYSTEM_EVENT_OBJECT_SCHEMA	SYS_DNAME	CHAR(10)	System schema name of the schema containing the subject table or view of the trigger.
SYSTEM_EVENT_OBJECT_TABLE	SYS_TNAME	CHAR(10)	System table name of the table or view that contains the subject table or view of the trigger.

SYSTYPES

The SYSTYPES table contains one row for each built-in data type and each distinct type and array type created by the CREATE TYPE statement.

The following table describes the columns in the SYSTYPES table:

Table 223. SYSTYPES table

Column Name	System Column Name	Data Type	Description
USER_DEFINED_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128)	Schema name of the data type.
USER_DEFINED_TYPE_NAME	TYPENAME	VARCHAR(128)	Name of the data type.
USER_DEFINED_TYPE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that created the data type.
SOURCE_SCHEMA	SRCSCHEMA	VARCHAR(128) Nullable	The schema for the source data type of this data type. Contains the null value if this is a built-in data type.

Table 223. SYSTYPES table (continued)

Column Name	System Column Name	Data Type	Description
SOURCE_TYPE	SRCTYPE	VARCHAR(128)	Name of the source data type of this data type.
		Nullable	Contains the null value if this is a built-in data type.
SYSTEM_TYPE_SCHEMA	SYSTSHEMA	CHAR(10)	System schema name of the data type.
SYSTEM_TYPE_NAME	SYSTNAME	CHAR(10)	System name of the data type.
METATYPE	METATYPE	CHAR(1)	Indicates the type of data type. A Array data type. S System predefined data type. T User-defined distinct type.
TYPERULES	TYPERULES	CHAR(1)	Indicates the type rules for the user-defined type. S Strong typing. W Weak typing. blank Not applicable.

Table 223. SYSTYPES table (continued)

Column Name	System Column Name	Data Type	Description
LENGTH	LENGTH	INTEGER	<p>The length attribute of the data type; or, in the case of a decimal, numeric, or nonzero precision binary column, its precision. For an array data type, it is the length of a single array element:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>Precision of number DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHARACTER</p> <p>Maximum length of string VARCHAR or CLOB</p> <p>Length of graphic string GRAPHIC</p> <p>Maximum length of graphic string VARGRAPHIC or DBCLOB</p> <p>Length of binary string BINARY</p> <p>Maximum length of binary string VARBINARY or BLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>Maximum length of datalink URL and comment DATALINK</p> <p>40 bytes ROWID</p> <p>2147483647 bytes XML</p> <p>Same value as the source type DISTINCT</p>
NUMERIC_SCALE	SCALE	SMALLINT	Scale of numeric data.
		Nullable	Contains the null value if the data type is not decimal, numeric, or binary.
CCSID	CCSID	INTEGER	The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK data types.
		Nullable	Contains the null value if the data type is numeric.

Table 223. SYSTYPES table (continued)

Column Name	System Column Name	Data Type	Description
STORAGE	STORAGE	INTEGER	<p>The storage requirements for the data type:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>(Precision/2) + 1 DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHAR</p> <p>Maximum length of string + 2 VARCHAR</p> <p>Maximum length of string + 29 CLOB</p> <p>Length of string * 2 GRAPHIC</p> <p>Maximum length of string * 2 + 2 VARGRAPHIC</p> <p>Maximum length of string * 2 + 29 DBCLOB</p> <p>Length of binary string BINARY</p> <p>Maximum length of binary string + 2 VARBINARY</p> <p>Maximum length of string + 29 BLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>Maximum length of datalink URL and comment + 24 DATALINK</p> <p>42 bytes ROWID</p> <p>2147483647 bytes + 29 XML</p> <p>Same value as the source type DISTINCT</p> <p>Note: This column supplies the storage requirements for all data types.</p>
NUMERIC_PRECISION	PRECISION	INTEGER Nullable	<p>The precision of all numeric data types.</p> <p>Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.</p> <p>Contains the null value if the data type is not numeric.</p>

Table 223. SYSTYPES table (continued)

Column Name	System Column Name	Data Type	Description
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the data type is not a string.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the data type is not a string.
ALLOCATE	ALLOCATE	INTEGER Nullable	Allocated length of the string for varying-length binary, varying-length character, varying-length graphic, and XML data types. Contains the null value for any other data type.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the data type is not numeric.
DATETIME_PRECISION	DATPRC	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the data type is not date, time, or timestamp.
CREATE_TIME	CRTTIME	TIMESTAMP Nullable	Identifies the timestamp when the data type was created.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number of the data type. 0 indicates the system ASP.
LAST_ALTERED	ALTEREDTS	TIMESTAMP Nullable	Reserved. Contains the null value.
NORMALIZE_DATA	NORMALIZE	VARCHAR(3) Nullable	Indicates whether the parameter value should be normalized or not. This attribute only applies to UTF-8 and UTF-16 data. NO The value should not be normalized. YES The value should be normalized.
TYPE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement (type text). Contains the null value if the type has no text.
MAXIMUM_CARDINALITY	MAXCARD	BIGINT Nullable	The maximum cardinality of the array data type. Contains the null value if the type is not an array type.

SYSUDTAUTH

The SYSUDTAUTH view contains one row for every privilege granted on a type. Note that this catalog view cannot be used to determine whether a user is authorized to a type because the privilege to use a type could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSUDTAUTH view:

Table 224. SYSUDTAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
USER_DEFINED_TYPE_SCHEMA	UDT_SCHEMA	VARCHAR(128)	Name of the schema
USER_DEFINED_TYPE_NAME	UDT_NAME	VARCHAR(128)	Name of the type
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the type. USAGE The privilege to use the type.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_TYPE_SCHEMA	SYSTSCHEMA	CHAR(10)	System name of the schema
SYSTEM_TYPE_NAME	SYSTNAME	CHAR(10)	System name of the type

SYSVARIABLEAUTH

The SYSVARIABLEAUTH view contains one row for every privilege granted on a global variable. Note that this catalog view cannot be used to determine whether a user is authorized to a global variable because the privilege to use a global variable could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSVARIABLEAUTH view:

Table 225. SYSVARIABLEAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
VARIABLE_SCHEMA	VARSCHHEMA	VARCHAR(128)	Name of the schema
VARIABLE_NAME	VARNAME	VARCHAR(128)	Name of the global variable

Table 225. SYSVARIABLEAUTH view (continued)

Column Name	System Column Name	Data Type	Description
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the global variable. READ The privilege to read the value of the global variable. WRITE The privilege to assign a value to the global variable.
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_VAR_SCHEMA	SYSVSCHEMA	CHAR(10)	System name of the schema
SYSTEM_VAR_NAME	SYSVNAME	CHAR(10)	System name of the global variable

SYSVARIABLEDEP

The SYSVARIABLEDEP table records the dependencies of variables.

The following table describes the columns in the SYSVARIABLEDEP table:

Table 226. SYSVARIABLEDEP table

Column name	System Column Name	Data Type	Description
VARIABLE_SCHEMA	VARSCHHEMA	VARCHAR(128)	Schema name of the variable.
VARIABLE_NAME	VARNAME	VARCHAR(128)	Name of the variable.
OBJECT_SCHEMA	BSCHHEMA	VARCHAR(128)	Name of the SQL schema that contains the object.
OBJECT_NAME	BNAME	VARCHAR(128)	Name of the object the variable is dependent on.
OBJECT_TYPE	BTYPE	CHAR(24)	Indicates the object type of the object referenced in the variable: ALIAS The object is an alias. FUNCTION The object is a function. MATERIALIZED QUERY TABLE The object is a materialized query table. SCHEMA The object is a schema. SEQUENCE The object is a sequence. TABLE The object is a table. TYPE The object is a distinct type. VARIABLE The object is a variable. VIEW The object is a view.

Table 226. SYSVARIABLEDEP table (continued)

Column name	System Column Name	Data Type	Description
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number of the object. 0 indicates the system ASP.
PARM_SIGNATURE	SIGNATURE	BLOB(3M) Nullable	This column identifies the routine signature. Contains the null value if the object is not a routine.

SYSVARIABLES

The SYSVARIABLES table contains one row for each global variable.

The following table describes the columns in the SYSVARIABLES table:

Table 227. SYSVARIABLES table

Column Name	System Column Name	Data Type	Description
VARIABLE_SCHEMA	VARSHEMA	VARCHAR(128)	Schema name of the variable.
VARIABLE_NAME	VARNAME	VARCHAR(128)	Name of the variable.
SYSTEM_VAR_SCHEMA	SYSVSCHEMA	CHAR(10)	System schema name.
SYSTEM_VAR_NAME	SYSVNAME	CHAR(10)	System variable name.
VARIABLE_OWNER	OWNER	VARCHAR(128)	Authorization ID of the owner of the global variable.
VARIABLE_DEFINER	DEFINER	VARCHAR(128)	Name of the user that created the variable.
VARIABLE_CREATED	CREATDTS	TIMESTAMP	Identifies the timestamp when the variable was created.
SCOPE	SCOPE	CHAR(1)	Indicates the scope of the variable: S Session
OWNER_TYPE	OWNER_TYPE	CHAR(1)	Indicates the owner of the variable: U The owner is an individual user S The variable is system owned.
USER_DEFINED_TYPE_SCHEMA	TYPESCHEMA	VARCHAR(128) Nullable	Schema of the data type if this is a distinct type. Contains the null value if the variable is not a distinct type.
USER_DEFINED_TYPE_NAME	TYPENAME	VARCHAR(128) Nullable	Name of the data type if this is a distinct type. Contains the null value if the variable is not a distinct type.

Table 227. SYSVARIABLES table (continued)

Column Name	System Column Name	Data Type	Description
DATA_TYPE	DATA_TYPE	VARCHAR(128)	Type of variable: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal FLOAT Floating point; FLOAT, REAL, or DOUBLE PRECISION DECFLOAT Decimal floating-point CHARACTER Fixed-length character string VARCHAR Varying-length character string CLOB Character large object string GRAPHIC Fixed-length graphic string VARGRAPHIC Varying-length graphic string DBCLOB Double-byte character large object string BINARY Fixed-length binary string VARBINARY Varying-length binary string BLOB Binary large object string DATE Date TIME Time TIMESTAMP Timestamp XML XML

Table 227. SYSVARIABLES table (continued)

Column Name	System Column Name	Data Type	Description
LENGTH	LENGTH	INTEGER	<p>The length attribute of the data type; or, in the case of a decimal, numeric, or nonzero precision binary variable, its precision:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>Precision of number DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHARACTER</p> <p>Maximum length of string VARCHAR or CLOB</p> <p>Length of graphic string GRAPHIC</p> <p>Maximum length of graphic string VARGRAPHIC or DBCLOB</p> <p>Length of binary string BINARY</p> <p>Maximum length of binary string VARBINARY or BLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>2147483647 bytes XML</p> <p>Same value as the source type DISTINCT</p>
NUMERIC_SCALE	SCALE	INTEGER Nullable	<p>Scale of numeric data.</p> <p>Contains the null value if the data type is not decimal, numeric, or binary.</p>

Table 227. SYSVARIABLES table (continued)

Column Name	System Column Name	Data Type	Description
STORAGE	STORAGE	INTEGER	<p>The storage requirements for the variable:</p> <p>8 bytes BIGINT</p> <p>4 bytes INTEGER</p> <p>2 bytes SMALLINT</p> <p>(Precision/2) + 1 DECIMAL</p> <p>Precision of number NUMERIC</p> <p>8 bytes FLOAT, FLOAT(n) where n = 25 to 53, or DOUBLE PRECISION</p> <p>4 bytes FLOAT(n) where n = 1 to 24, or REAL</p> <p>8 bytes DECFLOAT(16)</p> <p>16 bytes DECFLOAT(34)</p> <p>Length of string CHAR</p> <p>Maximum length of string + 2 VARCHAR</p> <p>Maximum length of string + 29 CLOB</p> <p>Length of string * 2 GRAPHIC</p> <p>Maximum length of string * 2 + 2 VARGRAPHIC</p> <p>Maximum length of string * 2 + 29 DBCLOB</p> <p>Length of binary string BINARY</p> <p>Maximum length of binary string + 2 VARBINARY</p> <p>Maximum length of string + 29 BLOB</p> <p>4 bytes DATE</p> <p>3 bytes TIME</p> <p>The integral part of ((p+1)/2)+7 where p is the precision of the timestamp TIMESTAMP</p> <p>2147483647 +29 bytes XML</p> <p>Same value as the source type DISTINCT</p> <p>Note: This column supplies the storage requirements for all data types.</p>
NUMERIC_PRECISION	PRECISION	INTEGER Nullable	<p>The precision of all numeric data types.</p> <p>Note: This column supplies the precision of all numeric data types, including decimal floating-point and single-and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.</p> <p>Contains the null value if the data type is not numeric.</p>
CCSID	CCSID	INTEGER Nullable	<p>The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK data types.</p> <p>Contains the null value if the data type is numeric.</p>

Table 227. SYSVARIABLES table (continued)

Column Name	System Column Name	Data Type	Description
CHARACTER_MAXIMUM_LENGTH	CHARLEN	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string data types and the XML data type. Contains the null value if the data type is not a string or XML.
CHARACTER_OCTET_LENGTH	CHARBYTE	INTEGER Nullable	Number of bytes for binary, character, and graphic string data types and the XML data type. Contains the null value if the data type is not a string or XML.
NUMERIC_PRECISION_RADIX	RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the data type is not numeric.
DATETIME_PRECISION	DATPRC	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the data type is not date, time, or timestamp.
DEFAULT	DEFAULT	DBCLOB(2M) CCSID 1200	The expression used to calculate the initial value of the global variable when it is first referenced.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number of the variable. 0 indicates the system ASP.
VARIABLE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement (type text). Contains the null value if the type has no text.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
DEFAULT_SCHEMA	QUALIFIER	VARCHAR(128) Nullable	Qualifier for unqualified tables and views.
SQL_PATH	SQL_PATH	VARCHAR(3483)	Identifies the path.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	Identifies the DECFLOAT rounding mode. C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP

Table 227. SYSVARIABLES table (continued)

Column Name	System Column Name	Data Type	Description
READONLY	READONLY	CHAR(1) Nullable	Indicates whether the variable may be modified or whether it is read-only. N Not read-only S Read-only because the global variable is maintained by the database manager.

SYSVIEWDEP

The SYSVIEWDEP view records the dependencies of views on tables, including the views of the SQL catalog.

The following table describes the columns in the SYSVIEWDEP view:

Table 228. SYSVIEWDEP view

Column name	System Column Name	Data Type	Description
VIEW_NAME	DNAME	VARCHAR(128)	Name of the view. This is the SQL view name if it exists; otherwise, it is the system view name.
VIEW_OWNER	DCREATOR	VARCHAR(128)	Owner of the view
OBJECT_NAME	ONAME	VARCHAR(128)	Name of the object the view is dependent on.
OBJECT_SCHEMA	OSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the object the view is dependent on.
OBJECT_TYPE	OTYPE	CHAR(24)	Type of object the view was based on: FUNCTION Function MATERIALIZED QUERY TABLE The object is a materialized query table. TABLE Table TYPE Distinct type VARIABLE The object is a variable. VIEW View
VIEW_SCHEMA	DDBNAME	VARCHAR(128)	Name of the schema of the view.
SYSTEM_VIEW_NAME	SYS_VNAME	CHAR(10)	System View name
SYSTEM_VIEW_SCHEMA	SYS_VDNAME	CHAR(10)	System View schema
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10) Nullable	System Table name. Contains the null value if the object is a function or distinct type.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10) Nullable	System Table schema. Contains the null value if the object is a function or distinct type.
TABLE_NAME	BNAME	VARCHAR(128) Nullable	Name of the table or view the view is dependent on. This is the SQL view name if it exists; otherwise, it is the system view name. Contains the null value if the object is a function or distinct type.
TABLE_OWNER	BCREATOR	VARCHAR(128) Nullable	Owner of the table or view the view is dependent on. Contains the null value if the object is a function or distinct type.

Table 228. SYSVIEWDEP view (continued)

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	BDBNAME	VARCHAR(128) Nullable	Name of the SQL schema that contains the table or view the view is dependent on. Contains the null value if the object is a function or distinct type.
TABLE_TYPE	BTYPE	CHAR(1) Nullable	Type of object the view was based on: T Table P Physical file M Materialized query table V View L Logical file Contains the null value if the object is a function or distinct type.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
PARM_SIGNATURE	SIGNATURE	BLOB(3M) Nullable	This column identifies the routine signature. Contains the null value if the object is not a routine.

SYSVIEWS

The SYSVIEWS view contains one row for each view in the SQL schema, including the views of the SQL catalog.

The following table describes the columns in the SYSVIEWS view:

Table 229. SYSVIEWS view

Column Name	System Column Name	Data Type	Description
TABLE_NAME	NAME	VARCHAR(128)	Name of the view. This is the SQL view name if it exists; otherwise, it is the system view name.
VIEW_OWNER	CREATOR	VARCHAR(128)	Owner of the view
SEQNO	SEQNO	INTEGER	Sequence number of this row; will always be 1.
CHECK_OPTION	CHECK	CHAR(1)	The check option used on the view N No check option was specified Y The local option was specified C The cascaded option was specified
VIEW_DEFINITION	TEXT	VARGRAPHIC(5000) CCSID 1200 Nullable	The query expression portion of the CREATE VIEW statement. Contains the null value if the view definition cannot be contained in the column without truncation.
IS_UPDATABLE	UPDATES	CHAR(1)	Specifies if the view is updatable: Y The view is updatable N The view is not updatable
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Name of the SQL schema that contains the view.
SYSTEM_VIEW_NAME	SYS_VNAME	CHAR(10)	System view name
SYSTEM_VIEW_SCHEMA	SYS_VDNAME	CHAR(10)	System view schema name

Table 229. SYSVIEWS view (continued)

Column Name	System Column Name	Data Type	Description
IS_INSERTABLE_INTO	INSERTABLE	VARCHAR(3)	Identifies whether an INSERT is allowed on the view. NO An INSERT is not allowed on this view. YES An INSERT is allowed on this view.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
IS_DELETABLE	DELETES	CHAR(1) Nullable	Specifies if the view is deletable: Y The view is deletable N The view is read-only
VIEW_DEFINER	DEFINER	VARCHAR(128)	Name of the user that defined the view.
ROUNDING_MODE	DECFLTRND	CHAR(1) Nullable	Indicates the DECFLOAT rounding mode of the view: C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP Contains the null value if the view does not have an expression that references a DECFLOAT column, function, or constant.

SYSXSROBJECTAUTH

The SYSXSROBJECTAUTH view contains one row for every privilege granted on an XML schema. Note that this catalog view cannot be used to determine whether a user is authorized to a XML schema because the privilege to use a XML schema could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSXSROBJECTAUTH view:

Table 230. SYSXSROBJECTAUTH view

Column Name	System Column Name	Data Type	Description
GRANTOR	GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
XSROBJECTSCHEMA	XSRSCHHEMA	VARCHAR(128)	Name of the schema
XSROBJECTNAME	XSRNAME	VARCHAR(128)	Name of the XML schema
PRIVILEGE_TYPE	PRIVTYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the XML schema. USAGE The privilege to use the XML schema.

Table 230. SYSXSROBJECTAUTH view (continued)

Column Name	System Column Name	Data Type	Description
IS_GRANTABLE	GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
AUTHORIZATION_LIST	AUTL	VARCHAR(10) Nullable	If the privilege is granted through an authorization, contains the name of the authorization list. Contains the null value if the privilege is not granted through an authorization list.
SYSTEM_XSR_SCHEMA	SYSXSCHEMA	CHAR(10)	System name of the schema
SYSTEM_XSR_NAME	SYSXNAME	CHAR(10)	System name of the XML schema

XSRANNOTATIONINFO

The XSRANNOTATIONINFO table contains one row for each annotation in an XML schema to record the table and column information about the annotation.

The following table describes the columns in the XSRANNOTATIONINFO table:

Table 231. XSRANNOTATIONINFO table

Column name	System Column Name	Data Type	Description
XSROBJECTID	OBJECTID	BIGINT	Internal identifier of the XML schema.
ANNOTATION_ID	ANNOID	INTEGER	Internal identifier of the XML schema annotation.
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Schema of the table to insert the data into.
TABLE_NAME	TABNAME	VARCHAR(128)	Table to insert the data into.
ROWSET	ROWSET	VARCHAR(1000)	Name of the rowset for this annotation.
COLUMN_NAME	COLNAME	VARCHAR(128)	Name of the column for this annotation.
DATA_TYPE	COLTYPE	INTEGER	Data type of the column for this annotation.
INSTANCE_TYPE	INSTTYPE	INTEGER	Type of data that will be provided by parser during decomposition: 2 decimal 4 long integer 5 integer 6 short integer 16 string 30 datetime 41 float 42 double
TRUNCATE	TRUNCATE	INTEGER	Indication of whether data can be truncated: 0 Data cannot be truncated 1 Data can be truncated

Table 231. XSRANNOTATIONINFO table (continued)

Column name	System Column Name	Data Type	Description
EXPRESSION	EXPRESSION	VARCHAR(1024) Nullable	Expression to be applied to data on insert by Db2.
CONDITION	CONDITION	VARCHAR(1024) Nullable	Condition to be applied before data is inserted by Db2.
CAST_EXPRESSION	CASTEXP	VARCHAR(20) Nullable	Cast expression to be applied when the column data is inserted by Db2 during decomposition.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.
ROWSET_ORDER	ORDER	INTEGER	RowSet order sequence. Default is 1.

XSROBJECTCOMPONENTS

The XSROBJECTCOMPONENTS table contains one row for each component (document) in an XML schema.

The following table describes the columns in the XSROBJECTCOMPONENTS table:

Table 232. XSROBJECTCOMPONENTS table

Column name	System Column Name	Data Type	Description
XSRCOMPONENTID	COMPID	BIGINT	Internal identifier of the XML schema document.
TARGETNAMESPACE	TGTNAMESPC	VARCHAR(1000) Nullable	String identifier for the target namespace.
SCHEMALOCATION	SCHEMALOC	VARCHAR(1000) Nullable	String identifier for the schema location.
COMPONENT	COMPONENT	BLOB(30M) Nullable	Contents of the XML schema document.
PROPERTIES	PROPERTIES	BLOB(5M) Nullable	Additional document property information for the XML schema document.
CREATED	CREATEDTS	TIMESTAMP	The time when the XSR_REGISTER stored procedure was executed for the XML schema.
STATUS	STATUS	CHAR(1)	Registration status of the XML schema: C Complete I Incomplete
IASP_NUMBER	IASPNUMBER	SMALLINT	Indicates the IASP where the catalog table is located. 0 indicates the system ASP.

XSROBJECTHIERARCHIES

The XSROBJECTHIERARCHIES table contains one row for each component (document) in an XML schema to record the XML schema document hierarchy relationship.

The following table describes the columns in the XSROBJECTHIERARCHIES table:

Table 233. XSROBJECTHIERARCHIES table

Column name	System Column Name	Data Type	Description
XSROBJECTID	OBJECTID	BIGINT	Internal identifier of the XML schema.
XSRCOMPONENTID	COMPID	BIGINT	Internal identifier of the XML schema document.

Table 233. XSROBJECTHIERARCHIES table (continued)

Column name	System Column Name	Data Type	Description
HTYPE	HTYPE	CHAR(1)	Hierarchy type: D Document P Primary document
TARGETNAMESPACE	TGTNAMESPC	VARCHAR(1000) Nullable	String identifier for the target namespace.
SCHEMALOCATION	SCHEMALOC	VARCHAR(1000) Nullable	String identifier for the schema location.
IASP_NUMBER	IASPNUMBER	SMALLINT	Specifies the independent auxiliary storage pool (IASP) number. 0 indicates the system ASP.

XSROBJECTS

The XSROBJECTS table contains one row for each registered XML schema.

The following table describes the columns in the XSROBJECTS table:

Table 234. XSROBJECTS table

Column name	System Column Name	Data Type	Description
XSROBJECTID	OBJECTID	BIGINT	Internal identifier of the XML schema.
XSROBJECTSCHEMA	XSRSCHEMA	VARCHAR(128)	Qualifier of the XML schema name.
XSROBJECTNAME	XSRNAME	VARCHAR(128)	Name of the XML schema
SYSTEM_XSR_SCHEMA	SYSXSCHEMA	CHAR(10)	System library name corresponding to the qualifier of the XML schema.
SYSTEM_XSR_NAME	SYSXNAME	CHAR(10)	System name of the XSROBJECT that correlates to the XML schema.
TARGETNAMESPACE	TGTNAMESPC	VARCHAR(1000) Nullable	String identifier for the target namespace.
SCHEMALOCATION	SCHEMALOC	VARCHAR(1000) Nullable	String identifier for the schema location.
XSR_OBJECT_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	A character string supplied with the LABEL statement. Contains the null value if there is no label.
GRAMMAR	GRAMMAR	BLOB(250M) Nullable	The internal binary representation of the XML schema as the result of an XML_COMPLETE.
PROPERTIES	PROPERTIES	BLOB(5M) Nullable	Additional document property information for the XML schema document.
XSR_SCHEMA_DEFINER	DEFINER	VARCHAR(128)	Authorization ID under which the XML schema was created.
XSR_SCHEMA_OWNER	OWNER	VARCHAR(128)	Authorization ID that owns the XML schema.
XSR_SCHEMA_CREATED	CREATEDTS	TIMESTAMP	The time when the XML schema document was registered.
STATUS	STATUS	CHAR(1)	Registration status of the XML schema: C Complete I Incomplete

Table 234. XSROBJECTS table (continued)

Column name	System Column Name	Data Type	Description
DECOMPOSITION	DECOMP	CHAR(1)	Indicates the decomposition status of the XSR object:
		Nullable	Y Enabled
			N Not enabled
VERSION	VERSION	VARCHAR(128)	Indicates the version used during decomposition.
		Nullable	
IASP_NUMBER	IASPNUMBER	SMALLINT	Indicates the IASP where the catalog table is located. 0 indicates the system ASP.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000)	A character string supplied with the COMMENT statement.
		CCSID 1200	
		Nullable	Contains the null value if there is no long comment.

ODBC and JDBC catalog views

The catalog includes the views and tables in the SYSIBM library displayed in this section.

View Name	Description
SQLCOLPRIVILEGES on page 1619	Information about privileges granted on columns
SQLCOLUMNS on page 1620	Information about column attributes
SQLFOREIGNKEYS on page 1629	Information about foreign keys
SQLFUNCTIONCOLS on page 1630	Information about function parameters
SQLFUNCTIONS on page 1638	Information about functions
SQLPRIMARYKEYS on page 1638	Information about primary keys
SQLPROCEDURECOLS on page 1638	Information about procedure parameters
SQLPROCEDURES on page 1647	Information about procedures
SQLSCHEMAS on page 1647	Information about schemas
SQLSPECIALCOLUMNS on page 1648	Information about columns of a table that can be used to uniquely identify a row
SQLSTATISTICS on page 1654	Statistical information about tables
SQLTABLEPRIVILEGES on page 1655	Information about privileges granted on tables
SQLTABLES on page 1655	Information about tables
SQLTYPEINFO on page 1656	Information about the types of tables
SQLUDTS on page 1663	Information about built-in data types and distinct types

SQLCOLPRIVILEGES

The SQLCOLPRIVILEGES view contains one row for every privilege granted on a column or a privilege granted on the column's table. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 235. SQLCOLPRIVILEGES view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name.
TABLE_SCHEM	VARCHAR(128)	Name of the SQL schema that contains the table.

Table 235. SQLCOLPRIVILEGES view (continued)

Column Name	Data Type	Description
TABLE_NAME	VARCHAR(128)	Table name.
COLUMN_NAME	VARCHAR(128)	Column name.
GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
PRIVILEGE	VARCHAR(10)	The privilege granted: UPDATE The privilege to update the column. REFERENCES The privilege to reference the column in a referential constraint.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
DBNAME	VARCHAR(8)	Reserved. The column contains the null value. Nullable

SQLCOLUMNS

The SQLCOLUMNS view contains one row for every column in a table, view, or alias.

The following table describes the columns in the view:

Table 236. SQLCOLUMNS view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name.
TABLE_SCHEM	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	VARCHAR(128)	Table name.
COLUMN_NAME	VARCHAR(128)	Column name.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
DATA_TYPE	SMALLINT	The data type of the column: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(261)	The name of the data type of the column: BIGINT BIGINT INTeger INTEGER SMALLINT SMALLINT DECIMAL DECIMAL NUMERIC NUMERIC FLOAT DOUBLE PRECISION REAL REAL DECFLOAT DECFLOAT CHARacter CHARACTER CHARacter FOR BIT DATA CHARACTER FOR BIT DATA VARCHAR VARCHAR VARCHAR FOR BIT DATA VARCHAR FOR BIT DATA CLOB CLOB GRAPHIC GRAPHIC VARGRAPHIC VARGRAPHIC DBCLOB DBCLOB NCHAR NCHAR NVARCHAR NVARCHAR NCLOB NCLOB BINARY BINARY VARBINARY VARBINARY BLOB BLOB DATE DATE TIME TIME TIMESTAMP TIMESTAMP DATALINK DATALINK ROWID ROWID XML XML Qualified Type Name DISTINCT
COLUMN_SIZE	INTEGER	The length of the column.
BUFFER_LENGTH	INTEGER	Indicates the length of the column in a buffer.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
DECIMAL_DIGITS	SMALLINT Nullable	Indicates the number of digits for a numeric column.
		Contains the null value if the object is not numeric or timestamp.
NUM_PREC_RADIX	SMALLINT Nullable	Indicates the radix of a numeric column.
		Contains the null value if the object is not numeric.
NULLABLE	SMALLINT	Indicates whether the column can contain the null value.
		0 The column does not allow nulls.
		1 The column does allow nulls.
REMARKS	VARCHAR(2000)	A character string supplied with the COMMENT statement.
	Nullable	Contains the null value if there is no long comment.
COLUMN_DEF	VARCHAR(2000)	The default value of the column.
	Nullable	Contains the null value if there is no default value.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
SQL_DATA_TYPE	SMALLINT	Indicates the SQL data type of the column.
	-5	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	-360	DECFLOAT
	1	CHARACTER
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	-99	CLOB
	-95	GRAPHIC
	-96	VARGRAPHIC
	-350	DBCLOB
	-8	NCHAR
	-9	NVARCHAR
	-10	NCLOB
	-98	BLOB
	9	DATE
	9	TIME
	9	TIMESTAMP
	70	DATALINK
	-100	ROWID
	-370	XML
	17	DISTINCT

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
SQL_DATETIME_SUB	SMALLINT Nullable	The datetime subtype of the data type: 1 DATE 2 TIME 3 TIMESTAMP Contains the null value if the column is not a datetime data type.
CHAR_OCTET_LENGTH	INTEGER Nullable	Indicates the length in bytes of the column. Contains the null value if the column is not a string.
ORDINAL_POSITION	INTEGER	Indicates the ordinal position of the column in the table.
IS_NULLABLE	VARCHAR(3)	Indicates whether the column can contain the null value. NO The column is not nullable. YES The column is nullable.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
JDBC_DATA_TYPE	SMALLINT	Indicates the JDBC data type of the column.
	-5	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	1111	DECFLOAT
	1	CHARACTER or GRAPHIC
	-15	NCHAR
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR or VARGRAPHIC
	-9	NVARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	2005	CLOB or DBCLOB
	2011	NCLOB
	2004	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	70	DATALINK
	-8	ROWID
	2009	XML
	2001	DISTINCT
SCOPE_CATALOG	VARCHAR(128)	Reserved. Contains the null value. Nullable
SCOPE_SCHEMA	VARCHAR(128)	Reserved. Contains the null value. Nullable
SCOPE_TABLE	VARCHAR(128)	Reserved. Contains the null value. Nullable
SOURCE_DATA_TYPE	SMALLINT	The source data type if the data type of the column is a distinct type. For values see JDBC_DATA_TYPE. Nullable Contains the null value if the data type is not a distinct type.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
DBNAME	VARCHAR(8) Nullable	Reserved. Contains the null value.
PSEUDO_COLUMN	SMALLINT	Indicates whether this is a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression column. 1 The column is not a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression column. 2 The column is a ROWID, identity, or row change timestamp, row begin, row end, transaction start ID, or generated expression column.
COLUMN_TEXT	VARCHAR(50) Nullable	The text of the column. Contains the null value if the column has no column text.
SYSTEM_COLUMN_NAME	CHAR(10)	The system name of the column.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
I_DATA_TYPE	SMALLINT	Indicates the IBM i CLI data type of the column.
	19	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	-360	DECFLOAT
	1	CHARACTER
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	14	CLOB
	95	GRAPHIC or NCHAR
	96	VARGRAPHIC or NVARCHAR
	15	DBCLOB or NCLOB
	13	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	16	DATALINK
	1111	ROWID
	-370	XML
	2001	DISTINCT
HIDDEN	CHAR(1)	Specifies whether the column is included in an implicit column list.
	P	Partially hidden.
	N	Not hidden.

Table 236. SQLCOLUMNS view (continued)

Column Name	Data Type	Description
HAS_DEFAULT	CHAR(1)	If the column has a default value (DEFAULT clause or null capable): N No Y Yes A The column has a ROWID data type and the GENERATED ALWAYS attribute. D The column has a ROWID data type and the GENERATED BY DEFAULT attribute. E The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED ALWAYS attribute. F The column is defined with the FOR EACH ROW ON UPDATE and the GENERATED BY DEFAULT attribute. I The column is defined with the AS IDENTITY and GENERATED ALWAYS attributes. J The column is defined with the AS IDENTITY and GENERATED BY DEFAULT attributes. Q The column is defined with the GENERATED AS ROW BEGIN attribute. R The column is defined with the GENERATED AS ROW END attribute. X The column is defined with the GENERATED AS TRANSACTION START ID attribute. a The column is defined as a generated expression using a special register. c The column is defined as a generated expression using a global variable. d The column is defined as a generated expression using DATA CHANGE OPERATION. If the column is for a view, N is returned.
SOURCE_TYPE_NAME	VARCHAR(128) Nullable	If the column data type is a user-defined type, the built-in data type name of its source type. Contains the null value if the column data type is not a user-defined type.
SOURCE_SQL_DATA_TYPE	SMALLINT Nullable	If the column data type is a user-defined type, the built-in SQL_DATA_TYPE of its source type. For values see SQL_DATA_TYPE. Contains the null value if the column data type is not a user-defined type.
SOURCE_JDBC_DATA_TYPE	SMALLINT Nullable	If the column data type is a user-defined type, the built-in JDBC_DATA_TYPE of its source type. For values see JDBC_DATA_TYPE. Contains the null value if the column data type is not a user-defined type.

SQLFOREIGNKEYS

The SQLFOREIGNKEYS view contains one row for every referential constraint key on a table.

The following table describes the columns in the view:

Table 237. SQLFOREIGNKEYS view

Column Name	Data Type	Description
PKTABLE_CAT	VARCHAR(128)	Relational database name
PKTABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema containing the parent table.
PKTABLE_NAME	VARCHAR(128)	Parent table name.
PKCOLUMN_NAME	VARCHAR(128)	Parent key column name.

Table 237. SQLFOREIGNKEYS view (continued)

Column Name	Data Type	Description
FKTABLE_CAT	VARCHAR(128)	Relational database name
FKTABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema containing the dependent table of the referential constraint.
FKTABLE_NAME	VARCHAR(128)	Dependent table name of the referential constraint.
FKCOLUMN_NAME	VARCHAR(128)	Dependent key name.
KEY_SEQ	SMALLINT	The position of the column within the key.
UPDATE_RULE	SMALLINT	Update Rule.
	1	RESTRICT
	3	NO ACTION
DELETE_RULE	SMALLINT	Delete Rule:
	0	CASCADE
	1	RESTRICT
	2	SET NULL
	3	NO ACTION
	4	SET DEFAULT
FK_NAME	VARCHAR(128)	Name of the referential constraint
PK_NAME	VARCHAR(128)	Name of the unique constraint
DEFERRABILITY	SMALLINT	Indicates whether the constraint checking can be deferred. Will always be 7.
UNIQUE_OR_PRIMARY	CHAR(7)	Indicates the type of parent constraint:
	PRIMARY	The parent constraint is a primary key.
	UNIQUE	The parent constraint is a unique constraint.

SQLFUNCTIONCOLS

The SQLFUNCTIONCOLS view contains one row for every parameter of a function. The result of a scalar function and the result columns of a table function are also returned.

The following table describes the columns in the view:

Table 238. SQLFUNCTIONCOLS view

Column Name	Data Type	Description
FUNCTION_CAT	VARCHAR(128)	Relational database name
FUNCTION_SCHEMA	VARCHAR(128)	Schema name of the function instance.
FUNCTION_NAME	VARCHAR(128)	Name of the function instance.
COLUMN_NAME	VARCHAR(128)	Name of a function parameter.
	Nullable	Contains the null value if the parameter does not have a name.
COLUMN_TYPE	SMALLINT	Type of the parameter:
	1	IN
	4	RETURN value
	5	Result column of a table function

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
DATA_TYPE	SMALLINT	The data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC or -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT 50 ARRAY

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(261)	The name of the data type of the parameter: BIGINT BIGINT INTeger INTEGER SMALLINT SMALLINT DECIMAL DECIMAL NUMERIC NUMERIC FLOAT DOUBLE PRECISION REAL REAL DECFLOAT DECFLOAT CHARacter CHARACTER CHARacter FOR BIT DATA CHARACTER FOR BIT DATA VARCHAR VARCHAR VARCHAR FOR BIT DATA VARCHAR FOR BIT DATA CLOB CLOB GRAPHIC GRAPHIC VARGRAPHIC VARGRAPHIC DBCLOB DBCLOB NCHAR NCHAR NVARCHAR NVARCHAR NCLOB NCLOB BINARY BINARY VARBINARY VARBINARY BLOB BLOB DATE DATE TIME TIME TIMESTAMP TIMESTAMP DATALINK DATALINK ROWID ROWID XML XML Qualified Type Name DISTINCT Array Type Name ARRAY
COLUMN_SIZE	INTEGER	Length of the parameter.

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
BUFFER_LENGTH	INTEGER	Indicates the length of the parameter in a buffer.
DECIMAL_DIGITS	SMALLINT Nullable	Scale of numeric or datetime data. Contains the null value if the parameter is not decimal, numeric, binary, time or timestamp.
NUM_PREC_RADIX	SMALLINT Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the parameter is not numeric.
NULLABLE	SMALLINT	Indicates whether the parameter is nullable. 0 The parameter does not allow nulls. 1 The parameter does allow nulls.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
COLUMN_DEF	DBCLOB(64K) CCSID 1200 Nullable	The expression string used to calculate the default value of a parameter, if one exists. If the default value is the null value, the expression string is the keyword NULL. Contains the null value if the parameter has no default.

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
SQL_DATA_TYPE	SMALLINT	The SQL data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 9 DATE 9 TIME 9 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT 50 ARRAY

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
SQL_DATETIME_SUB	SMALLINT Nullable	The datetime subtype of the parameter: 1 DATE 2 TIME 3 TIMESTAMP Contains the null value if the data type is not a datetime data type.
CHAR_OCTET_LENGTH	INTEGER Nullable	Indicates the length in characters of the parameter. Contains the null value if the column is not a string.
ORDINAL_POSITION	INTEGER	Numeric place of the parameter in the parameter list, ordered from left to right. For scalar functions, the result of the function has a value of 0. For table functions, the result columns are numbered from 1 (leftmost result column) to <i>n</i> (<i>n</i> th result column).
IS_NULLABLE	VARCHAR(3)	Indicates whether the parameter is nullable. NO The parameter does not allow nulls. YES The parameter does allow nulls.
SPECIFIC_NAME	VARCHAR(128)	Specific name of the function instance

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
JDBC_DATA_TYPE	INTEGER	The JDBC data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL 1111 DECFLOAT 1 CHARACTER or GRAPHIC -15 NCHAR -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR or VARGRAPHIC -9 NVARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY 2005 CLOB or DBCLOB 2011 NCLOB 2004 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -8 ROWID 2009 XML 2001 DISTINCT 2003 ARRAY

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
I_DATA_TYPE	INTEGER	Indicates the IBM i CLI data type of the parameter.
	19	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	-360	DECFLOAT
	1	CHARACTER
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	14	CLOB
	95	GRAPHIC or NCHAR
	96	VARGRAPHIC or NVARCHAR
	15	DBCLOB or NCLOB
	13	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	16	DATALINK
	1111	ROWID
	-370	XML
	2001	DISTINCT
	50	ARRAY
SOURCE_DATA_TYPE	SMALLINT Nullable	The source data type if the data type of the parameter is a distinct type. For values see JDBC_DATA_TYPE. Contains the null value if the data type is not a distinct type.
SOURCE_TYPE_NAME	VARCHAR(128) Nullable	If the parameter data type is a user-defined type, the built-in data type name of its source type. Contains the null value if the parameter data type is not a user-defined type.
SOURCE_SQL_DATA_TYPE	SMALLINT Nullable	If the parameter data type is a user-defined type, the built-in SQL_DATA_TYPE of its source type. For values see SQL_DATA_TYPE. Contains the null value if the parameter data type is not a user-defined type.

Table 238. SQLFUNCTIONCOLS view (continued)

Column Name	Data Type	Description
SOURCE_JDBC_DATA_TYPE	SMALLINT Nullable	If the parameter data type is a user-defined type, the built-in JDBC_DATA_TYPE of its source type. For values see JDBC_DATA_TYPE. Contains the null value if the parameter data type is not a user-defined type.
MAXIMUM_CARDINALITY	BIGINT Nullable	The maximum cardinality of the array data type. Contains the null value if the type is not an array type.

SQLFUNCTIONS

The SQLFUNCTIONS view contains one row for every function.

The following table describes the columns in the view:

Table 239. SQLFUNCTIONS view

Column Name	Data Type	Description
FUNCTION_CAT	VARCHAR(128)	Relational database name
FUNCTION_SCHEM	VARCHAR(128)	Name of the schema of the function instance.
FUNCTION_NAME	VARCHAR(128)	Name of the function.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
FUNCTION_TYPE	SMALLINT	Type of function: 1 Column or scalar function 2 Table function
SPECIFIC_NAME	VARCHAR(128)	Specific name of the function instance

SQLPRIMARYKEYS

The SQLPRIMARYKEYS view contains one row for every primary constraint key on a table.

The following table describes the columns in the view:

Table 240. SQLPRIMARYKEYS view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEM	VARCHAR(128)	Name of the schema containing the table with the primary key.
TABLE_NAME	VARCHAR(128)	Name of the table with the primary key.
COLUMN_NAME	VARCHAR(128)	Name of a primary key column.
KEY_SEQ	SMALLINT	The position of the column within the key.
PK_NAME	VARCHAR(128)	Name of the primary key constraint.

SQLPROCEDURECOLS

The SQLPROCEDURECOLS view contains one row for every parameter of a procedure.

The following table describes the columns in the view:

Table 241. SQLPROCEDURECOLS view

Column Name	Data Type	Description
PROCEDURE_CAT	VARCHAR(128)	Relational database name
PROCEDURE_SCHEM	VARCHAR(128)	Schema name of the procedure instance.

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure instance.
COLUMN_NAME	VARCHAR(128) Nullable	Name of a procedure parameter. Contains the null value if the parameter does not have a name.
COLUMN_TYPE	SMALLINT	Type of the parameter: 1 IN 2 INOUT 4 OUT

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
DATA_TYPE	SMALLINT	The data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT 50 ARRAY

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(261)	The name of the data type of the parameter: BIGINT BIGINT INTeger INTEGER SMALLINT SMALLINT DECIMAL DECIMAL NUMERIC NUMERIC FLOAT DOUBLE PRECISION REAL REAL DECFLOAT DECFLOAT CHARacter CHARACTER CHARacter FOR BIT DATA CHARACTER FOR BIT DATA VARCHAR VARCHAR VARCHAR FOR BIT DATA VARCHAR FOR BIT DATA CLOB CLOB GRAPHIC GRAPHIC VARGRAPHIC VARGRAPHIC DBCLOB DBCLOB NCHAR NCHAR NVARCHAR NVARCHAR NCLOB NCLOB BINARY BINARY VARBINARY VARBINARY BLOB BLOB DATE DATE TIME TIME TIMESTAMP TIMESTAMP DATALINK DATALINK ROWID ROWID XML XML Qualified Type Name DISTINCT Array Type Name ARRAY
COLUMN_SIZE	INTEGER	Length of the parameter.

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
BUFFER_LENGTH	INTEGER	Indicates the length of the parameter in a buffer.
DECIMAL_DIGITS	SMALLINT Nullable	Scale of numeric or datetime data. Contains the null value if the parameter is not decimal, numeric, binary, time or timestamp.
NUM_PREC_RADIX	SMALLINT Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the parameter is not numeric.
NULLABLE	SMALLINT	Indicates whether the parameter is nullable. 0 The parameter does not allow nulls. 1 The parameter does allow nulls.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
COLUMN_DEF	DBCLOB(64K) CCSID(1200) Nullable	The expression string used to calculate the default value of a parameter, if one exists. If the default value is the null value, the expression string is the keyword NULL. Contains the null value if the parameter has no default.

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
SQL_DATA_TYPE	SMALLINT	The SQL data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 9 DATE 9 TIME 9 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT 50 ARRAY

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
SQL_DATETIME_SUB	SMALLINT Nullable	The datetime subtype of the parameter: 1 DATE 2 TIME 3 TIMESTAMP Contains the null value if the data type is not a datetime data type.
CHAR_OCTET_LENGTH	INTEGER Nullable	Indicates the length in characters of the parameter. Contains the null value if the column is not a string.
ORDINAL_POSITION	INTEGER	Numeric place of the parameter in the parameter list, ordered from left to right.
IS_NULLABLE	VARCHAR(3)	Indicates whether the parameter is nullable. NO The parameter does not allow nulls. YES The parameter does allow nulls.
SPECIFIC_NAME	VARCHAR(128)	Specific name of the procedure instance.

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
JDBC_DATA_TYPE	INTEGER	The JDBC data type of the parameter: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL 1111 DECFLOAT 1 CHARACTER or GRAPHIC -15 NCHAR -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR or VARGRAPHIC -9 NVARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY 2005 CLOB or DBCLOB 2011 NCLOB 2004 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -8 ROWID 2009 XML 2001 DISTINCT 2003 ARRAY

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
I_DATA_TYPE	INTEGER	Indicates the IBM i CLI data type of the parameter.

	92	TIME
	93	TIMESTAMP
	16	DATALINK
	1111	ROWID
	-370	XML
	2001	DISTINCT
	50	ARRAY
SOURCE_TYPE_NAME	VARCHAR(128)	If the parameter data type is a user-defined type, the built-in data type name of its source type.
	Nullable	Contains the null value if the parameter data type is not a user-defined type.
SOURCE_SQL_DATA_TYPE	SMALLINT	If the parameter data type is a user-defined type, the built-in SQL_DATA_TYPE of its source type. For values see SQL_DATA_TYPE.
	Nullable	Contains the null value if the parameter data type is not a user-defined type.
SOURCE_JDBC_DATA_TYPE	SMALLINT	If the parameter data type is a user-defined type, the built-in JDBC_DATA_TYPE of its source type. For values see JDBC_DATA_TYPE.
	Nullable	Contains the null value if the parameter data type is not a user-defined type.

Table 241. SQLPROCEDURECOLS view (continued)

Column Name	Data Type	Description
MAXIMUM_CARDINALITY	BIGINT	The maximum cardinality of the array data type.
	Nullable	Contains the null value if the type is not an array type.

SQLPROCEDURES

The SQLPROCEDURES view contains one row for every procedure.

The following table describes the columns in the view:

Table 242. SQLPROCEDURES view

Column Name	Data Type	Description
PROCEDURE_CAT	VARCHAR(128)	Relational database name
PROCEDURE_SCHEM	VARCHAR(128)	Name of the schema of the procedure instance.
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure.
NUM_INPUT_PARAMS	INTEGER	Identifies the number of input parameters. 0 indicates that there are no input parameters.
NUM_OUTPUT_PARAMS	INTEGER	Identifies the number of output parameters. 0 indicates that there are no output parameters.
NUM_RESULT_SETS	SMALLINT	Identifies the maximum number of result sets returned. 0 indicates that there are no result sets.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
PROCEDURE_TYPE	SMALLINT	Reserved. Contains 0.
NUM_INOUT_PARAMS	INTEGER	Identifies the number of input/output parameters. 0 indicates that there are no input/output parameters.
SPECIFIC_NAME	VARCHAR(128)	Specific name of the procedure instance.

SQLSCHEMAS

The SQLSCHEMAS view contains one row for every schema.

The following table describes the columns in the view:

Table 243. SQLSCHEMAS view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEM	VARCHAR(128)	Name of the schema.
TABLE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
TABLE_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	Reserved. Contains the null value.
TYPE_CAT	VARCHAR(128) Nullable	Reserved. Contains the null value.
TYPE_SCHEM	VARCHAR(128) Nullable	Reserved. Contains the null value.

Table 243. SQLSCHEMAS view (continued)

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
SELF_REFERENCING_COL_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
REF_GENERATION	VARCHAR(128)	Reserved. Contains the null value. Nullable
DBNAME	VARCHAR(8)	Reserved. Contains the null value. Nullable
SCHEMA_TEXT	VARGRAPHIC(50) CCSID 1200 Nullable	A character string that describes the schema. Contains the empty string if there is no text.
SYSTEM_TABLE_SCHEMA	CHAR(10)	System schema name.

SQLSPECIALCOLUMNS

The SQLSPECIALCOLUMNS view contains one row for every column of a primary key, unique constraint, or unique index that can identify a row of the table.

The following table describes the columns in the view:

Table 244. SQLSPECIALCOLUMNS view

Column Name	Data Type	Description
SCOPE	SMALLINT	Reserved. Contains 0.
COLUMN_NAME	VARCHAR(128)	Column name

Table 244. SQLSPECIALCOLUMNS view (continued)

Column Name	Data Type	Description
DATA_TYPE	SMALLINT	The data type of the column: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA 12 VARCHAR -3 VARCHAR FOR BIT DATA 40 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -2 BINARY -3 VARBINARY 30 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -100 ROWID 17 DISTINCT

Table 244. SQLSPECIALCOLUMNS view (continued)

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(260)	The name of the data type of the parameter: BIGINT BIGINT INTeger INTEGER SMALLINT SMALLINT DECIMAL DECIMAL NUMERIC NUMERIC FLOAT DOUBLE PRECISION REAL REAL DECFLOAT DECFLOAT CHARacter CHARACTER CHARacter FOR BIT DATA CHARACTER FOR BIT DATA VARCHAR VARCHAR VARCHAR FOR BIT DATA VARCHAR FOR BIT DATA CLOB CLOB GRAPHIC GRAPHIC VARGRAPHIC VARGRAPHIC DBCLOB DBCLOB NCHAR NCHAR NVARCHAR NVARCHAR NCLOB NCLOB BINARY BINARY VARBINARY VARBINARY BLOB BLOB DATE DATE TIME TIME TIMESTAMP TIMESTAMP DATALINK DATALINK ROWID ROWID XML XML Qualified Type Name DISTINCT
COLUMN_SIZE	INTEGER	The length of the column.
BUFFER_LENGTH	INTEGER	Indicates the length of the column in a buffer.

Table 244. SQLSPECIALCOLUMNS view (continued)

Column Name	Data Type	Description
DECIMAL_DIGITS	SMALLINT	Indicates the number of digits for a numeric column.
	Nullable	Contains the null value if the column is not numeric.
PSEUDO_COLUMN	SMALLINT	Indicates whether this is a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression column.
	1	The column is not a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression column.
	2	The column is a ROWID, identity, row change timestamp, row begin, row end, transaction start ID, or generated expression column.
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEM	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	VARCHAR(128)	Name of the table.
NULLABLE	SMALLINT	Indicates whether the column can contain the null value.
	0	The column is not nullable.
	1	The column is nullable.

Table 244. SQLSPECIALCOLUMNS view (continued)

Column Name	Data Type	Description
JDBC_DATA_TYPE	SMALLINT	Indicates the JDBC data type of the column.
	-5	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	1111	DECFLOAT
	1	CHARACTER or GRAPHIC
	-15	NCHAR
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR or VARGRAPHIC
	-9	NVARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	2005	CLOB or DBCLOB
	2011	NCLOB
	2004	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	70	DATALINK
	-8	ROWID
	2009	XML
	2001	DISTINCT

Table 244. SQLSPECIALCOLUMNS view (continued)

Column Name	Data Type	Description
I_DATA_TYPE	SMALLINT	Indicates the IBM i CLI data type of the column.
	19	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	-360	DECFLOAT
	1	CHARACTER
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	14	CLOB
	95	GRAPHIC or NCHAR
	96	VARGRAPHIC or NVARCHAR
	15	DBCLOB or NCLOB
	13	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	16	DATALINK
	1111	ROWID
	-370	XML
	2001	DISTINCT
SOURCE_TYPE_NAME	VARCHAR(128) Nullable	If the column data type is a user-defined type, the built-in data type name of its source type. Contains the null value if the column data type is not a user-defined type.
SOURCE_SQL_DATA_TYPE	SMALLINT Nullable	If the column data type is a user-defined type, the built-in SQL_DATA_TYPE of its source type. For values see SQL_DATA_TYPE. Contains the null value if the column data type is not a user-defined type.
SOURCE_JDBC_DATA_TYPE	SMALLINT Nullable	If the column data type is a user-defined type, the built-in JDBC_DATA_TYPE of its source type. For values see JDBC_DATA_TYPE. Contains the null value if the column data type is not a user-defined type.

SQLSTATISTICS

The SQLSTATISTICS view contains statistic information about a table.

The following table describes the columns in the view:

Table 245. SQLSTATISTICS view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema of the table.
TABLE_NAME	VARCHAR(128)	Name of the table.
NON_UNIQUE	SMALLINT	Indicates whether an index prohibits duplicate keys on the table.
	Nullable	Contains the null value if the TYPE is 0.
INDEX_QUALIFIER	VARCHAR(128)	Name of the schema of the index.
	Nullable	Contains the null value if the TYPE is 0.
INDEX_NAME	VARCHAR(128)	Name of the index.
	Nullable	Contains the null value if the TYPE is 0.
TYPE	SMALLINT	Indicates the type of information returned:
	0	The number of rows in the table.
	3	An index on the table.
ORDINAL_POSITION	SMALLINT	Indicates the ordinal position of the key in the index.
	Nullable	Contains the null value if the TYPE is 0.
COLUMN_NAME	DBCLOB(2097152) CCSID 1200	If the key column is an expression, contains the expression. Contains the column name if the key column is not an expression.
	Nullable	Contains the null value if the TYPE is 0.
ASC_OR_DESC	CHAR(1)	Order of the column in the key:
	Nullable	A Ascending D Descending Contains the null value if the TYPE is 0.
CARDINALITY	BIGINT	The number of valid rows in all partitions or members of the table.
	Nullable	Contains the null value if the TYPE is 3.
PAGES	BIGINT	The number of 64K pages all partitions or members of the table.
	Nullable	Contains the null value if the TYPE is 3.
FILTER_CONDITION	DBCLOB(2097152) CCSID 1200	Indicates whether the index is a sparse index. search-condition This is an SQL index with a WHERE clause. empty-string This is a DDS-created select/omit index. Contains the null value if the TYPE is 0 or this is not a sparse index.
I_INDEXTYPE	INTEGER	Contains the type of the index.
	0	The TYPE is 0.
	1	The index is a PRIMARY KEY or keyed physical file.
	2	The index is an SQL index.
	3	The index is a keyed logical file.
	4	The index is a UNIQUE or REFERENTIAL constraint.

SQLTABLEPRIVILEGES

The SQLTABLEPRIVILEGES view contains one row for every privilege granted on a table. Note that this catalog view cannot be used to determine whether a user is authorized to a table or view because the privilege to use a table or view could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 246. SQLTABLEPRIVILEGES view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEM	VARCHAR(128)	Name of the SQL schema of the table.
TABLE_NAME	VARCHAR(128)	Name of the table.
GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
PRIVILEGE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the table. DELETE The privilege to delete rows from the table. INDEX The privilege to create an index on the table. INSERT The privilege to insert rows into the table. REFERENCES The privilege to reference the table in a referential constraint. SELECT The privilege to select rows from the table. UPDATE The privilege to update the table.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.
DBNAME	VARCHAR(8) Nullable	Reserved. Contains the null value.

SQLTABLES

The SQLTABLES view contains one row for every table, view, and alias.

The following table describes the columns in the view:

Table 247. SQLTABLES view

Column Name	Data Type	Description
TABLE_CAT	VARCHAR(128)	Relational database name
TABLE_SCHEM	VARCHAR(128)	Name of the schema containing the table.
TABLE_NAME	VARCHAR(128)	Name of the table.

Table 247. SQLTABLES view (continued)

Column Name	Data Type	Description
TABLE_TYPE	VARCHAR(24)	Indicates the type of the table: ALIAS The table is an alias. MATERIALIZED QUERY TABLE The object is a materialized query table. SYSTEM TABLE The table is a system table. TABLE The table is an SQL table or physical file. VIEW The table is an SQL view or logical file.
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no long comment.
TYPE_CAT	VARCHAR(128)	Reserved. Contains the null value. Nullable
TYPE_SCHEMA	VARCHAR(128)	Reserved. Contains the null value. Nullable
TYPE_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
SELF_REFERENCING_COLUMN_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
REF_GENERATION	VARCHAR(128)	Reserved. Contains the null value. Nullable
DBNAME	VARCHAR(8)	Reserved. Contains the null value. Nullable
TABLE_TEXT	VARGRAPHIC(50) CCSID 1200	A character string provided with the LABEL statement.

SQLTYPEINFO

The SQLTYPEINFO table contains one row for every built-in data type.

The following table describes the columns in the table:

Table 248. SQLTYPEINFO table

Column Name	Data Type	Description
TYPE_NAME	VARCHAR(128)	Name of the built-in data type: BIGINT BIGINT INTeger INTEGER SMALLINT SMALLINT DECIMAL DECIMAL NUMERIC NUMERIC FLOAT DOUBLE PRECISION REAL REAL DECFLOAT DECFLOAT CHARacter CHARACTER CHARacter FOR BIT DATA CHARACTER FOR BIT DATA VARCHAR VARCHAR VARCHAR FOR BIT DATA VARCHAR FOR BIT DATA CLOB CLOB GRAPHIC GRAPHIC VARGRAPHIC VARGRAPHIC DBCLOB DBCLOB NCHAR NCHAR NVARCHAR NVARCHAR NCLOB NCLOB BINARY BINARY VARBINARY VARBINARY BLOB BLOB DATE DATE TIME TIME TIMESTAMP TIMESTAMP DATALINK DATALINK ROWID ROWID XML XML

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
DATA_TYPE	SMALLINT	The data type of the built-in data type: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -99 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 2001 DISTINCT
COLUMN_SIZE	INTEGER Nullable	The maximum length of the data type.
LITERAL_PREFIX	VARCHAR(128) Nullable	Indicates the prefix for a string literal. Contains the null value if the data type is not a string.

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
LITERAL_SUFFIX	VARCHAR(128) Nullable	Indicates the suffix for a string literal. Contains the null value if the data type is not a string.
CREATE_PARAMS	VARCHAR(128) Nullable	Indicates the parameters supported with the data type. length The parameter is a length. Returned for all string data types and DATALINK. precision,scale The parameters include precision and scale. Returned for the DECIMAL and NUMERIC data types. precision The parameters include precision. Returned for the DECFLOAT and TIMESTAMP data type. Contains the null value for all other data types.
NULLABLE	SMALLINT Nullable	Indicates whether the data type is nullable. 0 The data type does not allow nulls. 1 The data type does allow nulls.
CASE_SENSITIVE	SMALLINT Nullable	Indicates whether the data type is case sensitive. 0 The data type is not case sensitive. 1 The data type is case sensitive.
SEARCHABLE	SMALLINT Nullable	Indicates whether the data type can be used in a predicate. 0 The data type cannot be used in predicates. 2 The data type can be used in all predicates except the LIKE predicate. 3 The data type can be used in all predicates including the LIKE predicate.
UNSIGNED_ATTRIBUTE	SMALLINT Nullable	Indicates whether the numeric data type is signed or unsigned. 0 The data type is signed. 1 The data type is unsigned. Contains the null value if the data type is not numeric.
FIXED_PREC_SCALE	SMALLINT Nullable	Indicates whether the data type has a fixed precision and scale. 0 The data type does not have a fixed precision and scale. 1 The data type does have a fixed precision and scale. Contains the null value if the data type is not numeric.
AUTO_UNIQUE_VALUE	SMALLINT Nullable	Indicates whether the numeric data type is auto-incrementing: 0 The data type is not auto-incrementing. 1 The data type is auto-incrementing. Contains the null value if the data type is not numeric.
LOCAL_TYPE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
MINIMUM_SCALE	SMALLINT Nullable	Indicates the minimum scale of numeric data types. Contains the null value if the data type is not numeric.
MAXIMUM_SCALE	SMALLINT Nullable	Indicates the maximum scale of numeric data types. Contains the null value if the data type is not numeric.

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
SQL_DATA_TYPE	SMALLINT Nullable	Indicates the SQL data type value of the data type: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL -360 DECFLOAT 1 CHARACTER -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY -99 CLOB -95 GRAPHIC -96 VARGRAPHIC -350 DBCLOB -8 NCHAR -9 NVARCHAR -10 NCLOB -98 BLOB 9 DATE 9 TIME 9 TIMESTAMP 70 DATALINK -100 ROWID -370 XML 17 DISTINCT

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
SQL_DATETIME_SUB	SMALLINT Nullable	The datetime subtype of the data type: 1 DATE 2 TIME 3 TIMESTAMP Contains the null value if the data type is not a datetime data type.
NUM_PREC_RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the parameter is not numeric.
INTERVAL_PRECISION	SMALLINT Nullable	Reserved. Contains the null value.

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
JDBC_DATA_TYPE	SMALLINT	The JDBC data type value of the data type:
	-5	BIGINT
	4	INTEGER
	5	SMALLINT
	3	DECIMAL
	2	NUMERIC
	8	DOUBLE PRECISION
	7	REAL
	1111	DECFLOAT
	1	CHARACTER or GRAPHIC
	-15	NCHAR
	-2	CHARACTER FOR BIT DATA or BINARY
	12	VARCHAR or VARGRAPHIC
	-9	NVARCHAR
	-3	VARCHAR FOR BIT DATA or VARBINARY
	2005	CLOB or DBCLOB
	2011	NCLOB
	2004	BLOB
	91	DATE
	92	TIME
	93	TIMESTAMP
	70	DATALINK
	-8	ROWID
	2009	XML
	2001	DISTINCT

Table 248. SQLTYPEINFO table (continued)

Column Name	Data Type	Description
I_DATA_TYPE	SMALLINT	Indicates the IBM i CLI data type of the data type.
19	BIGINT	
4	INTEGER	
5	SMALLINT	
3	DECIMAL	
2	NUMERIC	
8	DOUBLE PRECISION	
7	REAL	
-360	DECFLOAT	
1	CHARACTER	
-2	CHARACTER FOR BIT DATA or BINARY	
12	VARCHAR	
-3	VARCHAR FOR BIT DATA or VARBINARY	
14	CLOB	
95	GRAPHIC or NCHAR	
96	VARGRAPHIC or NVARCHAR	
15	DBCLOB or NCLOB	
13	BLOB	
91	DATE	
92	TIME	
93	TIMESTAMP	
16	DATALINK	
1111	ROWID	
-370	XML	
2001	DISTINCT	

SQLUDTS

The SQLUDTS view contains one row for every distinct type.

The following table describes the columns in the view:

Table 249. SQLUDTS view

Column Name	Data Type	Description
TYPE_CAT	VARCHAR(128)	Relational database name
TYPE_SCHEM	VARCHAR(128)	Name of the schema containing the user-defined type.
TYPE_NAME	VARCHAR(128)	Name of the user-defined type.

Table 249. SQLUDTS view (continued)

Column Name	Data Type	Description
CLASS_NAME	VARCHAR(20)	<p>Java class name of the user-defined type.</p> <p>java.math.BigInteger BIGINT</p> <p>java.lang.Integer INTEGER</p> <p>java.lang.Short SMALLINT</p> <p>java.math.BigDecimal DECIMAL</p> <p>java.sql.BigDecimal NUMERIC</p> <p>java.lang.Double DOUBLE PRECISION</p> <p>java.lang.Float REAL</p> <p>java.math.BigDecimal DECFLOAT</p> <p>java.lang.String CHARACTER</p> <p>byte[] CHARACTER FOR BIT DATA</p> <p>java.lang.String VARCHAR</p> <p>byte[] VARCHAR FOR BIT DATA</p> <p>java.sql.Clob CLOB</p> <p>java.lang.String GRAPHIC</p> <p>java.lang.String VARGRAPHIC</p> <p>java.sql.Clob DBCLOB</p> <p>byte[] BINARY</p> <p>byte[] VARBINARY</p> <p>java.sql.Blob BLOB</p> <p>java.sql.Date DATE</p> <p>java.sql.Time TIME</p> <p>java.sql.Timestamp TIMESTAMP</p> <p>java.net.URL DATALINK</p> <p>byte[] ROWID</p> <p>java.sql.SQLXML XML</p>
DATA_TYPE	SMALLINT	Reserved. Contains 2001.

Table 249. SQLUDTS view (continued)

Column Name	Data Type	Description
BASE_TYPE	SMALLINT	The source data type of the user-defined data type: -5 BIGINT 4 INTEGER 5 SMALLINT 3 DECIMAL 2 NUMERIC 8 DOUBLE PRECISION 7 REAL 1111 DECFLOAT 1 CHARACTER or GRAPHIC -15 NCHAR -2 CHARACTER FOR BIT DATA or BINARY 12 VARCHAR or VARGRAPHIC -9 NVARCHAR -3 VARCHAR FOR BIT DATA or VARBINARY 2005 CLOB or DBCLOB 2011 NCLOB 2004 BLOB 91 DATE 92 TIME 93 TIMESTAMP 70 DATALINK 1111 ROWID 2009 XML
REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	A character string supplied with the COMMENT statement. Contains the null value if there is no comment.

ANS and ISO catalog views

There are two versions of some of the ANS and ISO catalog views. The version documented is the normal set of ANS and ISO views. A second set of views have names that are limited to no more than 18 characters and other than the view names are not documented in this book.

The ANS and ISO catalog includes the following tables in the QSYS2 library:

View Name	Shorter View Name	Description
"SQL_FEATURES" on page 1687		Information about features supported by the database manager
"SQL_LANGUAGES" on page 1687	SQL_LANGUAGES_S	Information about the supported languages
"SQL_SIZING" on page 1688		Information about the limits supported by the database manager

The ANS and ISO catalog includes the following views and tables in the SYSIBM and QSYS2 libraries:

View Name	Shorter View Name	Description
"AUTHORIZATIONS" on page 1666		Information about authorization IDs
"CHARACTER_SETS" on page 1667	CHARACTER_SETS_S	Information about supported CCSIDs
"CHECK_CONSTRAINTS" on page 1667		Information about check constraints
"COLUMN_PRIVILEGES" on page 1667		Information about column privileges
"COLUMNS" on page 1668	COLUMNS_S	Information about columns
"INFORMATION_SCHEMA_CATALOG_NAME" on page 1672	CATALOG_NAME	Information about the relational database
"PARAMETERS" on page 1672	PARAMETERS_S	Information about procedure parameters
"REFERENTIAL_CONSTRAINTS" on page 1676	REF_CONSTRAINTS	Information about referential constraints
"ROUTINE_PRIVILEGES" on page 1685	RTNPRI	Information about routine privileges
"ROUTINES" on page 1677	ROUTINES_S	Information about routines
"SCHEMATA" on page 1686	SCHEMATA_S	Statistical information about schemas
"SEQUENCES" on page 1686		Information about sequences
"TABLE_CONSTRAINTS" on page 1689		Information about constraints
"TABLE_PRIVILEGES" on page 1689		Information about table privileges
"TABLES" on page 1690	TABLES_S	Information about tables
"UDT_PRIVILEGES" on page 1690	UDTPRI	Information about type privileges
"USAGE_PRIVILEGES" on page 1691	USAGEPRIV	Information about sequence and XML schema privileges
"USER_DEFINED_TYPES" on page 1692	UDT_S	Information about types
"VARIABLE_PRIVILEGES" on page 1695	VARPRI	Information about global variable privileges
"VIEWS" on page 1695		Information about views

AUTHORIZATIONS

The AUTHORIZATIONS view contains one row for every authorization ID.

The following table describes the columns in the view:

Table 250. AUTHORIZATIONS view

Column Name	Data Type	Description
AUTHORIZATION_NAME	VARCHAR(128)	Authorization ID name
AUTHORIZATION_TYPE	VARCHAR(4)	The type of authorization ID. Contains 'USER'.

Table 250. AUTHORIZATIONS view (continued)

Column Name	Data Type	Description
AUTHORIZATION_ATTR	VARCHAR(5)	The type of user profile. Contains 'USER' or 'GROUP'.
AUTHORIZATION_TEXT	VARCHAR(50)	The text description for the profile.

CHARACTER_SETS

The CHARACTER_SETS view contains one row for every CCSID supported.

The following table describes the columns in the view:

Table 251. CHARACTER_SETS view

Column Name	Data Type	Description
CHARACTER_SET_CATALOG	VARCHAR(128)	Relational database name
CHARACTER_SET_SCHEMA	VARCHAR(128)	The schema name of the character set. Contains 'SYSIBM'.
CHARACTER_SET_NAME	VARCHAR(128)	The character set name.
FORM_OF_USE	VARCHAR(128)	Reserved. Contains the null value. Nullable
NUMBER_OF_CHARACTERS	INTEGER	Reserved. Contains the null value. Nullable
DEFAULT_COLLATE_CATALOG	VARCHAR(128)	Reserved.
DEFAULT_COLLATE_SCHEMA	VARCHAR(128)	Reserved.
DEFAULT_COLLATE_NAME	VARCHAR(128)	Reserved.

CHECK_CONSTRAINTS

The CHECK_CONSTRAINTS view contains one row for every check constraint.

The following table describes the columns in the view:

Table 252. CHECK_CONSTRAINTS view

Column Name	Data Type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	Relational database name
CONSTRAINT_SCHEMA	VARCHAR(128)	Name of the schema containing the constraint
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint
CHECK_CLAUSE	VARGRAPHIC(2000) CCSID 1200 Nullable	Text of the check constraint clause Contains the null value if the check clause cannot be contained in the column without truncation.

COLUMN_PRIVILEGES

The COLUMN_PRIVILEGES view contains one row for every privilege granted on a column. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ).

Furthermore, the privilege to use a column is also acquired through privileges granted on the table.

The following table describes the columns in the view:

Table 253. COLUMN_PRIVILEGES view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.

Table 253. COLUMN_PRIVILEGES view (continued)

Column Name	Data Type	Description
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	VARCHAR(128)	Name of the table.
COLUMN_NAME	VARCHAR(128)	Name of the column.
PRIVILEGE_TYPE	VARCHAR(10)	<p>The privilege granted:</p> <p>UPDATE The privilege to update the column.</p> <p>REFERENCES The privilege to reference the column in a referential constraint.</p>
IS_GRANTABLE	VARCHAR(3)	<p>Indicates whether the privilege is grantable to other users.</p> <p>NO The privilege is not grantable.</p> <p>YES The privilege is grantable.</p>

COLUMNS

The COLUMNS view contains one row for every column.

The following table describes the columns in the view:

Table 254. COLUMNS view

Column Name	Data Type	Description
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema containing the table or view
TABLE_NAME	VARCHAR(128)	Name of the table or view that contains the column
COLUMN_NAME	VARCHAR(128)	Name of the column
ORDINAL_POSITION	INTEGER	Numeric place of the column in the table or view, ordered from left to right
COLUMN_DEFAULT	VARGRAPHIC(2000) CCSID 1200 Nullable	<p>The default value of a column, if one exists. If the default value of the column cannot be represented without truncation, then the value of the column is the string 'TRUNCATED'. The default value is stored in character form. The following special values also exist:</p> <p>CURRENT_DATE The default value is the current date.</p> <p>CURRENT_TIME The default value is the current time.</p> <p>CURRENT_TIMESTAMP The default value is the current timestamp.</p> <p>NULL The default value is the null value and DEFAULT NULL was explicitly specified.</p> <p>USER The default value is the current job user.</p> <p>special-register When column HAS_DEFAULT contains the value 'a', the name of the special register.</p> <p>global-variable When column HAS_DEFAULT contains the value 'c', the qualified name of the global variable.</p> <p>DATA CHANGE OPERATION When column HAS_DEFAULT contains the value 'd'.</p> <p>Contains the null value if:</p> <ul style="list-style-type: none"> • The column has no default value. For example, if the column has an IDENTITY attribute, is a row ID, or is a row change timestamp, row begin, row end, or transaction start ID column or • A DEFAULT value was not explicitly specified.

Table 254. COLUMNS view (continued)

Column Name	Data Type	Description
IS_NULLABLE	VARCHAR(3)	Indicates whether the column can contain null values: NO The column cannot contain null values. YES The column can contain null values.
DATA_TYPE	VARCHAR(128)	Type of column: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Double-precision floating point REAL Single-precision floating point DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string NATIONAL CHARACTER National character NATIONAL CHARACTER VARYING Varying-length national character NATIONAL CHARACTER LARGE OBJECT National character large object BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML USER-DEFINED Distinct type

Table 254. COLUMNS view (continued)

Column Name	Data Type	Description
CHARACTER_MAXIMUM_LENGTH	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
CHARACTER_OCTET_LENGTH	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the column is not a string.
NUMERIC_PRECISION	INTEGER Nullable	The precision of all numeric columns. Note: This column supplies the precision of all numeric data types, including single-and double-precision floating point and decimal floating-point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if the column is not numeric.
NUMERIC_PRECISION_RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the column is not numeric.
NUMERIC_SCALE	INTEGER Nullable	Scale of numeric data. Contains the null value if the column is not decimal, numeric, or binary.
DATETIME_PRECISION	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the column is not a date, time, or timestamp.
INTERVAL_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
INTERVAL_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
CHARACTER_SET_CATALOG	VARCHAR(128) Nullable	Relational database name Contains the null value if the column is not a string.
CHARACTER_SET_SCHEMA	VARCHAR(128) Nullable	The schema name of the character set. Contains SYSIBM. Contains the null value if the column is not a string.
CHARACTER_SET_NAME	VARCHAR(128) Nullable	The character set name. Contains the null value if the column is not a string.
COLLATION_CATALOG	VARCHAR(128) Nullable	Relational database name Contains the null value if the column is not a string.
COLLATION_SCHEMA	VARCHAR(128) Nullable	The schema of the collation. Contains SYSIBM. Contains the null value if the column is not a string.
COLLATION_NAME	VARCHAR(128) Nullable	The collation name. Contains IBMDEFAULT. Contains the null value if the column is not a string.
DOMAIN_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
DOMAIN_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.

Table 254. COLUMNS view (continued)

Column Name	Data Type	Description
DOMAIN_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
UDT_CATALOG	VARCHAR(128) Nullable	The relational database name if this is a distinct type. Contains the null value if this is not a distinct type.
UDT_SCHEMA	VARCHAR(128) Nullable	The name of the schema if this is a distinct type. Contains the null value if this is not a distinct type.
UDT_NAME	VARCHAR(128) Nullable	The name of the distinct type. Contains the null value if this is not a distinct type.
SCOPE_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
SCOPE_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
SCOPE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
MAXIMUM_CARDINALITY	INTEGER Nullable	Reserved. Contains the null value.
DTD_IDENTIFIER	VARCHAR(128) Nullable	A unique internal identifier for the column.
IS_SELF_REFERENCING	VARCHAR(3)	Reserved. Contains 'NO'.
IS_IDENTITY	VARCHAR(3)	This column identifies whether the column is an identity column. NO The column is not an identity column. YES The column is an identity column.
IDENTITY_GENERATION	VARCHAR(10) Nullable	This column identifies whether the column is GENERATED ALWAYS or GENERATED BY DEFAULT. ALWAYS The column value is always generated. BY DEFAULT The column value is generated by default. Contains the null value if the column is not a ROWID, IDENTITY, or row change timestamp column.
IDENTITY_START	DECIMAL(31,0) Nullable	Starting value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_INCREMENT	DECIMAL(31,0) Nullable	Increment value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MAXIMUM	DECIMAL(31,0) Nullable	Maximum value of the identity column. Contains the null value if the column is not an IDENTITY column.
IDENTITY_MINIMUM	DECIMAL(31,0) Nullable	Minimum value of the identity column. Contains the null value if the column is not an IDENTITY column.

Table 254. COLUMNS view (continued)

Column Name	Data Type	Description
IDENTITY_CYCLE	VARCHAR(3) Nullable	This column identifies whether the identity column values will continue to be generated after the minimum or maximum value has been reached. NO Values will not continue to be generated. YES Values will continue to be generated. Contains the null value if the column is not an IDENTITY column.
IS_GENERATED	VARCHAR(5)	Reserved. Contains 'NEVER'.
GENERATION_EXPRESSION	VARCHAR(128) Nullable	Reserved. Contains the null value.
IS_SYSTEM_TIME_PERIOD_START	VARCHAR(3)	This column identifies whether the column is a row begin column. NO The column is not a row begin column. YES The column is a row begin column.
IS_SYSTEM_TIME_PERIOD_END	VARCHAR(3)	This column identifies whether the column is a row end column. NO The column is not a row end column. YES The column is a row end column.
SYSTEM_TIME_PERIOD_TIMESTAMP_GENERATION	VARCHAR(6) Nullable	This column identifies the row begin or row end generation attribute. ALWAYS This column is a row begin or row end column that is GENERATED ALWAYS. Contains the null value if it is not a row begin or row end column.
IS_UPDATABLE	VARCHAR(3)	This column identifies whether the column is updatable. NO The column cannot be updated. YES The column can be updated.
DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.

INFORMATION_SCHEMA_CATALOG_NAME

The INFORMATION_SCHEMA_CATALOG_NAME view contains one row for the relational database.

The following table describes the columns in the view:

Table 255. INFORMATION_SCHEMA_CATALOG_NAME view

Column Name	Data Type	Description
CATALOG_NAME	VARCHAR(128)	Relational database name

PARAMETERS

The PARAMETERS view contains one row for each parameter of a routine in the relational database.

The following table describes the columns in the view:

Table 256. PARAMETERS view

Column Name	Data Type	Description
SPECIFIC_CATALOG	VARCHAR(128)	Relational database name
SPECIFIC_SCHEMA	VARCHAR(128)	Schema name of the routine instance
SPECIFIC_NAME	VARCHAR(128)	Specific name of the routine instance
ORDINAL_POSITION	INTEGER	Numeric place of the parameter in the parameter list, ordered from left to right.
PARAMETER_MODE	VARCHAR(5)	The type of the parameter: IN This is an input parameter. OUT This is an output parameter. INOUT This is an input/output parameter.
IS_RESULT	VARCHAR(3)	Reserved. Contains 'NO'.
AS_LOCATOR	VARCHAR(3)	Indicates whether the parameter was specified as a locator. NO The parameter was not specified as a locator. YES The parameter was specified as a locator.
PARAMETER_NAME	VARCHAR(128) Nullable	The name of the parameter Contains the null value if the parameter does not have a name.
FROM_SQL_SPECIFIC_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
FROM_SQL_SPECIFIC_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
FROM_SQL_SPECIFIC_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
TO_SQL_SPECIFIC_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
TO_SQL_SPECIFIC_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
TO_SQL_SPECIFIC_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.

Table 256. PARAMETERS view (continued)

Column Name	Data Type	Description
DATA_TYPE	VARCHAR(128) Nullable	Type of the parameter: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Floating point; DOUBLE PRECISION REAL Floating point; REAL DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string NATIONAL CHARACTER National character NATIONAL CHARACTER VARYING Varying-length national character NATIONAL CHARACTER LARGE OBJECT National character large object BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML USER-DEFINED Distinct type or array type
CHARACTER_MAXIMUM_LENGTH	INTEGER Nullable	Maximum length of the string for binary, character, and graphic string and XML data types. Contains the null value if the parameter is not a string.
CHARACTER_OCTET_LENGTH	INTEGER Nullable	Number of bytes for binary, character, and graphic string and XML data types. Contains the null value if the parameter is not a string.

Table 256. PARAMETERS view (continued)

Column Name	Data Type	Description
CHARACTER_SET_CATALOG	VARCHAR(128) Nullable	Relational database name Contains the null value if the column is not a string.
CHARACTER_SET_SCHEMA	VARCHAR(128) Nullable	The schema name of the character set. Contains 'SYSIBM'. Contains the null value if the column is not a string.
CHARACTER_SET_NAME	VARCHAR(128) Nullable	The character set name. Contains the null value if the column is not a string.
COLLATION_CATALOG	VARCHAR(128) Nullable	Relational database name Contains the null value if the column is not a string.
COLLATION_SCHEMA	VARCHAR(128) Nullable	The schema of the collation. SYSIBM is returned. Contains the null value if the column is not a string.
COLLATION_NAME	VARCHAR(128) Nullable	The collation name. IBMDEFAULT is returned. Contains the null value if the column is not a string.
NUMERIC_PRECISION	INTEGER Nullable	The precision of all numeric parameters. Note: This column supplies the precision of all numeric data types, including single-and double-precision floating point and decimal floating-point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if the parameter is not numeric.
NUMERIC_PRECISION_RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the parameter is not numeric.
NUMERIC_SCALE	INTEGER Nullable	Scale of numeric data. Contains the null value if not decimal, numeric, or binary parameter.
DATETIME_PRECISION	INTEGER Nullable	The fractional part of a date, time, or timestamp. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the parameter is not a date, time, or timestamp.
INTERVAL_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
INTERVAL_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
UDT_CATALOG	VARCHAR(128) Nullable	The relational database name if this is a distinct type or array type.. Contains the null value if this is not a distinct type or array type.
UDT_SCHEMA	VARCHAR(128) Nullable	The name of the schema if this is a distinct type or array type. Contains the null value if this is not a distinct type or array type.
UDT_NAME	VARCHAR(128) Nullable	The name of the distinct type or array type. Contains the null value if this is not a distinct type or array type.
SCOPE_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.

Table 256. PARAMETERS view (continued)

Column Name	Data Type	Description
SCOPE_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
SCOPE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
MAXIMUM_CARDINALITY	BIGINT Nullable	The maximum cardinality of the array type if this parameter is an array type. Contains the null value if this parameter is not an array type.
DTD_IDENTIFIER	VARCHAR(128) Nullable	A unique internal identifier for the parameter.
DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.
PARAMETER_DEFAULT	DBCLOB(64K) CCSID 1200 Nullable	The expression string used to calculate the default value of a parameter, if one exists. If the default value is the null value, the expression string is the keyword NULL. Contains the null value if the parameter has no default.

REFERENTIAL_CONSTRAINTS

The REFERENTIAL_CONSTRAINTS view contains one row for each referential constraint.

The following table describes the columns in the view:

Table 257. REFERENTIAL_CONSTRAINTS view

Column Name	Data Type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	Relational database name
CONSTRAINT_SCHEMA	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint.
UNIQUE_CONSTRAINT_CATALOG	VARCHAR(128)	Relational database name containing the unique constraint referenced by the referential constraint.
UNIQUE_CONSTRAINT_SCHEMA	VARCHAR(128)	Name of the SQL schema containing the unique constraint referenced by the referential constraint.
UNIQUE_CONSTRAINT_NAME	VARCHAR(128)	Name of the unique constraint referenced by the referential constraint.
MATCH_OPTION	VARCHAR(7)	Reserved. Contains 'NONE'.
UPDATE_RULE	VARCHAR(11)	Update Rule. <ul style="list-style-type: none"> • NO ACTION • RESTRICT
DELETE_RULE	VARCHAR(11)	Delete Rule <ul style="list-style-type: none"> • NO ACTION • CASCADE • SET NULL • SET DEFAULT • RESTRICT
COLUMN_COUNT	INTEGER	Count of columns in the constraint.

ROUTINES

The ROUTINES view contains one row for each routine.

The following table describes the columns in the view:

Table 258. ROUTINES view

Column Name	Data Type	Description
SPECIFIC_CATALOG	VARCHAR(128)	Relational database name
SPECIFIC_SCHEMA	VARCHAR(128)	Schema name of the routine instance.
SPECIFIC_NAME	VARCHAR(128)	Specific name of the routine.
ROUTINE_CATALOG	VARCHAR(128)	Relational database name
ROUTINE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the routine.
ROUTINE_NAME	VARCHAR(128)	Name of the routine.
ROUTINE_TYPE	VARCHAR(15)	Type of the routine. PROCEDURE This is a procedure. FUNCTION This is a function. INSTANCE METHOD This is a built-in data type function created for a distinct type.
MODULE_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
MODULE_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
MODULE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
UDT_CATALOG	VARCHAR(128) Nullable	Relational database name. Contains the null value if this is not an INSTANCE METHOD.
UDT_SCHEMA	VARCHAR(128) Nullable	Name of the SQL schema that contains the distinct type related to this function. Contains the null value if this is not an INSTANCE METHOD.
UDT_NAME	VARCHAR(128) Nullable	Name of the distinct type name related to this function. Contains the null value if this is not an INSTANCE METHOD.

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
DATA_TYPE	VARCHAR(128) Nullable	Type of the result of the function: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Floating point; DOUBLE PRECISION REAL Floating point; REAL DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string NATIONAL CHARACTER National character NATIONAL CHARACTER VARYING Varying-length national character NATIONAL CHARACTER LARGE OBJECT National character large object BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML USER-DEFINED Distinct type or Array type Contains the null value if this is not a scalar function.
CHARACTER_MAXIMUM_LENGTH	INTEGER Nullable	Maximum length of the result string of the function for binary, character, and graphic string and XML data types. Contains the null value if this is not a scalar function or the parameter is not a string.

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
CHARACTER_OCTET_LENGTH	INTEGER Nullable	Number of bytes for the result string of the function for binary, character, and graphic string and XML data types. Contains the null value if this is not a scalar function or the parameter is not a string.
CHARACTER_SET_CATALOG	VARCHAR(128) Nullable	Relational database name of the result of the function. Contains the null value if this is not a scalar function or the result is not a string.
CHARACTER_SET_SCHEMA	VARCHAR(128) Nullable	The schema name of the character set of the result of the function. Contains 'SYSIBM'. Contains the null value if this is not a scalar function or the result is not a string.
CHARACTER_SET_NAME	VARCHAR(128) Nullable	The character set name of the result of the function. Contains the null value if this is not a scalar function or the result is not a string.
COLLATION_CATALOG	VARCHAR(128) Nullable	Relational database name of the result of the function. Contains the null value if this is not a scalar function or the result is not a string.
COLLATION_SCHEMA	VARCHAR(128) Nullable	The schema of the collation of the result of the function. SYSIBM is returned. Contains the null value if this is not a scalar function or the result is not a string.
COLLATION_NAME	VARCHAR(128) Nullable	The collation name of the result of the function. IBMDEFAULT is returned. Contains the null value if this is not a scalar function or the result is not a string.
NUMERIC_PRECISION	INTEGER Nullable	The precision of the result of the function. Note: This column supplies the precision of all numeric data types, including single-and double-precision floating point and decimal floating-point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if this is not a scalar function or the result is not numeric.
NUMERIC_PRECISION_RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if this is not a scalar function or the result is not numeric.
NUMERIC_SCALE	INTEGER Nullable	Scale of numeric result of the function. Contains the null value if this is not a scalar function or the result is not numeric.
DATETIME_PRECISION	INTEGER Nullable	The fractional part of a date, time, or timestamp result of the function. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if this is not a scalar function or the result is not a date, time, or timestamp.
INTERVAL_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
INTERVAL_PRECISION	INTEGER Nullable	Reserved. Contains the null value.

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
TYPE_UDT_CATALOG	VARCHAR(128) Nullable	The relational database name if the result of the function is a distinct type or array type. Contains the null value if this is not a scalar function or the result is not a distinct type or array type.
TYPE_UDT_SCHEMA	VARCHAR(128) Nullable	The name of the schema if the result of the function is a distinct type or array type. Contains the null value if this is not a scalar function or the result is not a distinct type or array type.
TYPE_UDT_NAME	VARCHAR(128) Nullable	The name of the distinct type if the result of the function is a distinct type or array type. Contains the null value if this is not a scalar function or the result is not a distinct type or array type.
SCOPE_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
SCOPE_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
SCOPE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
MAXIMUM_CARDINALITY	BIGINT Nullable	The maximum cardinality of the array type if the result of the function is an array type. Contains the null value if this is not an array type.
DTD_IDENTIFIER	VARCHAR(128) Nullable	A unique internal identifier for the result of the function.
ROUTINE_BODY	VARCHAR(8)	The type of the routine body: EXTERNAL This is an external routine. SQL This is an SQL routine.
ROUTINE_DEFINITION	DBCLOB(2M) CCSID 13488 Nullable	If this is an SQL routine, this column contains the SQL routine body. If this is an obfuscated routine, the text starts with the WRAPPED keyword and is followed by the encoded form of the statement text. Contains the null value if this is not an SQL routine or if the routine body cannot be contained in this column without truncation.
EXTERNAL_NAME	VARCHAR(279) Nullable	If this is an external routine, this column identifies the external program name. <ul style="list-style-type: none">• For REXX, the external program name is <i>schema-name/source-file-name(member-name)</i>.• For ILE service programs, the external program name is <i>schema-name/service-program-name(entry-point-name)</i>.• For Java programs, the external program name is an optional jar-id followed by a <i>fully-qualified-class-name/method-name</i> or <i>fully-qualified-class-name.method-name</i>.• For all other languages, the external program name is <i>schema-name/program-name</i>. Contains the null value if this is a system-generated function or a function sourced on a built-in function.

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
EXTERNAL_LANGUAGE	VARCHAR(8) Nullable	If this is an external routine, this column identifies the external program's language. C The external program is written in C. C++ The external program is written in C++. CL The external program is written in CL. COBOL The external program is written in COBOL. COBOLLE The external program is written in ILE COBOL. FORTRAN The external program is written in FORTRAN. JAVA The external program is written in JAVA. PLI The external program is written in PL/I. REXX The external program is a REXX procedure. RPG The external program is written in RPG. RPGLE The external program is written in ILE RPG. Contains the null value if this is not an external routine.
PARAMETER_STYLE	VARCHAR(18) Nullable	If this is an external routine, this column identifies the parameter style (calling convention). DB2GENERAL This is the DB2GENERAL calling convention. DB2SQL This is the DB2SQL calling convention. GENERAL This is the GENERAL calling convention. JAVA This is the JAVA calling convention. GENERAL WITH NULLS This is the GENERAL WITH NULLS calling convention. SQL This is the SQL standard calling convention. Contains the null value if this is not an external routine.
IS_DETERMINISTIC	VARCHAR(3)	This column identifies whether the routine is deterministic. That is, whether a call to the routine with the same arguments will always return the same result. NO The routine is not deterministic. YES The routine is deterministic.
SQL_DATA_ACCESS	VARCHAR(17)	This column identifies whether a routine contains SQL and whether it reads or modifies data. NO SQL The routine does not contain any SQL statements. CONTAINS SQL The routine contains SQL statements. READS SQL DATA The routine possibly reads data from a table or view. MODIFIES SQL DATA The routine possibly modifies data in a table or view or issues SQL DDL statements.

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
IS_NULL_CALL	VARCHAR(3) Nullable	<p>Identifies whether the function needs to be called if an input parameter is the null value.</p> <p>NO This function need not be called if an input parameter is the null value. If this is a scalar function, the result of the function is implicitly null if any of the operands are null. If this is a table function, the result of the function is an empty table if any of the operands are the null value.</p> <p>YES This function must be called even if an input operand is null. Contains the null value if this is not a function.</p>
SQL_PATH	VARCHAR(3483) Nullable	<p>If this is an SQL routine, this column identifies the path.</p> <p>Contains the null value if this is not an SQL routine.</p>
SCHEMA_LEVEL_ROUTINE	VARCHAR(3)	Reserved. Contains 'YES'.
MAX_DYNAMIC_RESULT_SETS	SMALLINT	Identifies the maximum number of result sets returned. 0 indicates that there are no result sets.
IS_USER_DEFINED_CAST	VARCHAR(3) Nullable	<p>Identifies whether the this function is a cast function created when a distinct type was created.</p> <p>NO This function is not a cast function.</p> <p>YES This function is a cast function. Contains the null value if the routine is not a function.</p>
IS_IMPLICITLY_INVOCABLE	VARCHAR(3) Nullable	<p>Identifies whether the this function is a cast function created when a distinct type was created and can be implicitly invoked.</p> <p>NO This function is not a cast function.</p> <p>YES This function is a cast function and can be implicitly invoked. Contains the null value if the routine is not a function.</p>
SECURITY_TYPE	VARCHAR(22) Nullable	<p>Reserved. Contains 'IMPLEMENTATION DEFINED' if this is an external routine.</p> <p>Contains the null value if the routine is not an external routine.</p>
TO_SQL_SPECIFIC_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
TO_SQL_SPECIFIC_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
TO_SQL_SPECIFIC_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
AS_LOCATOR	VARCHAR(3) Nullable	<p>Indicates whether the result was specified as a locator.</p> <p>NO The parameter was not specified as a locator.</p> <p>YES The parameter was specified as a locator. Contains the null value if this is not a scalar function.</p>
CREATED	TIMESTAMP	Identifies the timestamp when the routine was created.
LAST_ALTERED	TIMESTAMP Nullable	Timestamp when routine was last altered. Contains null if the routine has never been altered.
NEW_SAVEPOINT_LEVEL	VARCHAR(3) Nullable	<p>Indicates whether the routine starts a new savepoint level.</p> <p>NO A new savepoint level is not started when the procedure is called.</p> <p>YES A new savepoint level is started when the procedure is called.</p>

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
IS_UDT_DEPENDENT	VARCHAR(3)	Indicates whether the routine is dependent on a UDT. NO The routine is not dependent on a UDT. YES The routine is dependent on a UDT.
RESULT_CAST_FROM_DATA_TYPE	VARCHAR(128) Nullable	Type of the parameter: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Floating point; DOUBLE PRECISION REAL Floating point; REAL DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string NATIONAL CHARACTER National character NATIONAL CHARACTER VARYING Varying-length national character NATIONAL CHARACTER LARGE OBJECT National character large object BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML USER-DEFINED Distinct Type

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
RESULT_CAST_AS_LOCATOR	VARCHAR(3)	Indicates whether the result is cast from a locator.
	Nullable	NO The result is not cast from a locator.
		YES The result is cast from a locator.
RESULT_CAST_CHAR_MAX_LENGTH	INTEGER	Maximum length of the string for binary, character, and graphic string and XML data types.
	Nullable	Contains the null value if the parameter is not a string.
RESULT_CAST_CHAR_OCTET_LENGTH	INTEGER	Number of bytes for binary, character, and graphic string and XML data types.
	Nullable	Contains the null value if the parameter is not a string.
RESULT_CAST_CHAR_SET_CATALOG	VARCHAR(128)	Relational database name
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_CHAR_SET_SCHEMA	VARCHAR(128)	The schema name of the character set. Contains 'SYSIBM'.
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_CHAR_SET_NAME	VARCHAR(128)	The character set name.
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_COLLATION_CATALOG	VARCHAR(128)	Relational database name
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_COLLATION_SCHEMA	VARCHAR(128)	The schema of the collation. SYSIBM is returned.
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_COLLATION_NAME	VARCHAR(128)	The collation name. IBMDEFAULT is returned.
	Nullable	Contains the null value if the column is not a string.
RESULT_CAST_NUMERIC_PRECISION	INTEGER	The precision of all numeric parameters.
	Nullable	Note: This column supplies the precision of all numeric data types, including single-and double-precision floating point and decimal floating-point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits.
		Contains the null value if the parameter is not numeric.
RESULT_CAST_NUMERIC_RADIX	INTEGER	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits:
	Nullable	2 Binary; floating-point precision is specified in binary digits.
		10 Decimal; all other numeric types are specified in decimal digits.
		Contains the null value if the parameter is not numeric.
RESULT_CAST_NUMERIC_SCALE	INTEGER	Scale of numeric data.
	Nullable	Contains the null value if not decimal, numeric, or binary parameter.
RESULT_CAST_DATETIME_PRECISION	INTEGER	The fractional part of a date, time, or timestamp.
	Nullable	0 For DATE and TIME data types
		0-12 For TIMESTAMP data types (number of fractional seconds).
		Contains the null value if the parameter is not a date, time, or timestamp.
RESULT_CAST_INTERVAL_TYPE	VARCHAR(128)	Reserved. Contains the null value.
	Nullable	
RESULT_CAST_INTERVAL_PRECISION	INTEGER	Reserved. Contains the null value.
	Nullable	

Table 258. ROUTINES view (continued)

Column Name	Data Type	Description
RESULT_CAST_TYPE_UDT_CATALOG	VARCHAR(128) Nullable	The relational database name if this is a distinct type. Contains the null value if this is not a distinct type.
RESULT_CAST_TYPE_UDT_SCHEMA	VARCHAR(128) Nullable	The name of the schema if this is a distinct type. Contains the null value if this is not a distinct type.
RESULT_CAST_TYPE_UDT_NAME	VARCHAR(128) Nullable	The name of the distinct type Contains the null value if this is not a distinct type.
RESULT_CAST_SCOPE_CATALOG	VARCHAR(128) Nullable	Reserved. Contains the null value.
RESULT_CAST_SCOPE_SCHEMA	VARCHAR(128) Nullable	Reserved. Contains the null value.
RESULT_CAST_SCOPE_NAME	VARCHAR(128) Nullable	Reserved. Contains the null value.
RESULT_CAST_MAX_CARDINALITY	INTEGER Nullable	Reserved. Contains the null value.
RESULT_CAST_DTD_IDENTIFIER	VARCHAR(128) Nullable	A unique internal identifier for the parameter.
DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.
RESULT_CAST_FROM_DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
RESULT_CAST_DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
RESULT_CAST_DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.

ROUTINE_PRIVILEGES

The ROUTINE_PRIVILEGES view contains one row for every privilege granted on a routine. Note that this catalog view cannot be used to determine whether a user is authorized to a routine because the privilege to use a routine could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 259. ROUTINE_PRIVILEGES view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
SPECIFIC_CATALOG	VARCHAR(128)	Relational database name
SPECIFIC_SCHEMA	VARCHAR(128)	Schema name of the routine instance.
SPECIFIC_NAME	VARCHAR(128)	Specific name of the routine.

Table 259. ROUTINE_PRIVILEGES view (continued)

Column Name	Data Type	Description
ROUTINE_CATALOG	VARCHAR(128)	Relational database name
ROUTINE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the routine.
ROUTINE_NAME	VARCHAR(128)	Name of the routine.
PRIVILEGE_TYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the routine. EXECUTE The privilege to execute the routine.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.

SCHEMATA

The SCHEMATA view contains one row for each schema.

The following table describes the columns in the view:

Table 260. SCHEMATA view

Column Name	Data Type	Description
CATALOG_NAME	VARCHAR(128)	Relational database name
SCHEMA_NAME	VARCHAR(128)	Name of the schema
SCHEMA_OWNER	VARCHAR(128)	Owner of the schema
DEFAULT_CHARACTER_SET_CATALOG	VARCHAR(128)	Relational database name
DEFAULT_CHARACTER_SET_SCHEMA	VARCHAR(128)	The schema name of the default character set. Contains 'SYSIBM'.
DEFAULT_CHARACTER_SET_NAME	VARCHAR(128)	The default character set name.
SQL_PATH	VARCHAR(4096)	Reserved. Contains the null value. Nullable

SEQUENCES

The SEQUENCES view contains one row for each sequence.

The following table describes the columns in the view:

Table 261. SEQUENCES view

Column Name	Data Type	Description
SEQUENCE_CATALOG	VARCHAR(128)	Relational database name
SEQUENCE_SCHEMA	VARCHAR(128)	SQL schema that contains the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
DATA_TYPE	VARCHAR(128)	Type of the sequence
NUMERIC_PRECISION	INTEGER	The precision of the sequence type
NUMERIC_PRECISION_RADIX	INTEGER	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 10 All sequence data types are specified in decimal digits.
NUMERIC_SCALE	INTEGER	All sequence data types use 0 scale
START_VALUE	DECIMAL(63,0)	Starting value of the sequence
MINIMUM_VALUE	DECIMAL(63,0)	Minimum value of the sequence

Table 261. SEQUENCES view (continued)

Column Name	Data Type	Description
MAXIMUM_VALUE	DECIMAL(63,0)	Maximum value of the sequence
INCREMENT	INTEGER	Increment value of the sequence
CYCLE_OPTION	VARCHAR(3)	Identifies whether the sequence values will continue to be generated after the minimum or maximum value has been reached. NO Values will not continue to be generated YES Values will continue to be generated
DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.

SQL_FEATURES

The SQL_FEATURES table contains one row for each feature supported by the database manager.

The following table describes the columns in the table:

Table 262. SQL_FEATURES table

Column Name	Data Type	Description
FEATURE_ID	VARCHAR(7) Nullable	ANS and ISO feature ID
FEATURE_NAME	VARCHAR(128)	The name of the ANS and ISO feature.
SUB FEATURE_ID	VARCHAR(7) Nullable	ANS and ISO subfeature ID
SUB FEATURE_NAME	VARCHAR(256)	The name of the ANS and ISO subfeature.
IS_SUPPORTED	VARCHAR(3)	Indicates whether the feature is supported: YES This feature is supported. NO This feature is not supported.
IS_VERIFIED_BY	VARCHAR(128) Nullable	Reserved. Contains the null value.
COMMENTS	VARCHAR(2000) Nullable	Reserved. Contains the null value.

SQL_LANGUAGES

The SQL_LANGUAGES table contains one row for every SQL language binding and programming language for which conformance is claimed.

The following table describes the columns in the SQL_LANGUAGES table:

Table 263. SQL_LANGUAGES table

Column Name	Data Type	Description
SQL_LANGUAGE_SOURCE	VARCHAR(254)	Name of the standard.
SQL_LANGUAGE_YEAR	VARCHAR(254)	Year in which the standard was approved.

Table 263. SQL_LANGUAGES table (continued)

Column Name	Data Type	Description
SQL_LANGUAGE_CONFORMANCE	VARCHAR(254) Nullable	<p>Level of conformance.</p> <p>2 For the 1987 and 1989 standards, indicates that Level 2 conformance is claimed.</p> <p>ENTRY For the 1992 standard, indicates that Entry Level conformance is claimed.</p> <p>CORE For the 1999 standard, indicates that Core Level is conformance is claimed.</p> <p>Contains the null value if conformance is not yet claimed.</p>
SQL_LANGUAGE_INTEGRITY	VARCHAR(254) Nullable	<p>Support of the integrity feature.</p> <p>YES conformance is claimed to the integrity feature</p> <p>NO conformance is not claimed to the integrity feature</p> <p>Contains the null value if the standard does not have a separate integrity feature.</p>
SQL_LANGUAGE_IMPLEMENTATION	VARCHAR(254) Nullable	Reserved. Contains the null value.
SQL_LANGUAGE_BINDING_STYLE	VARCHAR(254)	<p>The style of binding of the SQL language</p> <p>EMBEDDED support for embedded SQL for the language in SQL_LANGUAGE_PROGRAMMING_LANG</p> <p>DIRECT DIRECT SQL is supported (for example Interactive SQL)</p> <p>CLI Support for CLI for the language in SQL_LANGUAGE_PROGRAMMING_LANG</p>
SQL_LANGUAGE_PROGRAMMING_LANG	VARCHAR(254) Nullable	<p>The language supported by EMBEDDED or CLI.</p> <p>C The C language is supported.</p> <p>COBOL The COBOL language is supported.</p> <p>PLI The PL/I language is supported.</p> <p>Contains the null value if the SQL_LANGUAGE_BINDING_STYLE is DIRECT.</p>

SQL_SIZING

The SQL_SIZING table contains one row for each limit supported by the database manager.

The following table describes the columns in the table:

Table 264. SQL_SIZING table

Column Name	Data Type	Description
SIZING_ID	INTEGER	ANS and ISO sizing ID
SIZING_NAME	VARCHAR(128)	Name of the ANS and ISO sizing.
SUPPORTED_VALUE	DECIMAL(21) Nullable	<p>Indicates the sizing limit.</p> <p>Contains the null value if the sizing limit is not applicable.</p>
COMMENTS	VARCHAR(2000) Nullable	Reserved. Contains the null value.

TABLE_CONSTRAINTS

The TABLE_CONSTRAINTS view contains one row for each constraint.

The following table describes the columns in the view:

Table 265. TABLE_CONSTRAINTS view

Column Name	Data Type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	Relational database name
CONSTRAINT_SCHEMA	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint.
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the schema containing the table.
TABLE_NAME	VARCHAR(128)	Name of the table which the constraint is created over.
CONSTRAINT_TYPE	VARCHAR(11)	Constraint Type <ul style="list-style-type: none">• CHECK• UNIQUE• PRIMARY KEY• FOREIGN KEY
IS_DEFERRABLE	VARCHAR(3)	Indicates whether the constraint checking can be deferred. Contains 'NO'.
INITIALLY_DEFERRED	VARCHAR(3)	Indicates whether the constraint was defined as initially deferred. Contains 'NO'.

TABLE_PRIVILEGES

The TABLE_PRIVILEGES view contains one row for every privilege granted on a table. Note that this catalog view cannot be used to determine whether a user is authorized to a table because the privilege to use a table could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 266. TABLE_PRIVILEGES view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	VARCHAR(128)	Name of the table.
PRIVILEGE_TYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the table. DELETE The privilege to delete rows from the table. INDEX The privilege to create an index on the table. INSERT The privilege to insert rows into the table. REFERENCES The privilege to reference the table in a referential constraint. SELECT The privilege to select rows from the table. UPDATE The privilege to update the table.

Table 266. TABLE_PRIVILEGES view (continued)

Column Name	Data Type	Description
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.

TABLES

The TABLES view contains one row for each table, view, and alias.

The following table describes the columns in the view:

Table 267. TABLES view

Column Name	Data Type	Description
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table, view or alias.
TABLE_NAME	VARCHAR(128)	Name of the table, view or alias.
TABLE_TYPE	VARCHAR(24)	Indicates the type of the table: ALIAS The table is an alias. BASE TABLE The table is an SQL table or physical file. MATERIALIZED QUERY TABLE The object is a materialized query table. VIEW The table is an SQL view or logical file.
SELF_REFERENCING_COLUMN_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
REFERENCE_GENERATION	VARCHAR(128)	Reserved. Contains the null value. Nullable
USER_DEFINED_TYPE_CATALOG	VARCHAR(128)	Reserved. Contains the null value. Nullable
USER_DEFINED_TYPE_SCHEMA	VARCHAR(128)	Reserved. Contains the null value. Nullable
USER_DEFINED_TYPE_NAME	VARCHAR(128)	Reserved. Contains the null value. Nullable
IS_INSERTABLE_INTO	VARCHAR(3)	Identifies whether an INSERT is allowed on the table. NO An INSERT is not allowed on this table. YES An INSERT is allowed on this table.

UDT_PRIVILEGES

The UDT_PRIVILEGES view contains one row for every privilege granted on a type. Note that this catalog view cannot be used to determine whether a user is authorized to a type because the privilege to use a type could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 268. UDT_PRIVILEGES view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
UDT_CATALOG	VARCHAR(128)	Relational database name
UDT_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the type.
UDT_NAME	VARCHAR(128)	Name of the type.
PRIVILEGE_TYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the type. USAGE The privilege to use the type.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.

USAGE_PRIVILEGES

The USAGE_PRIVILEGES view contains one row for every privilege granted on a sequence or XML schema. Note that this catalog view cannot be used to determine whether a user is authorized to a sequence or XML schema because the privilege to use a sequence or XML schema could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 269. USAGE_PRIVILEGES view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128)	Reserved. Contains the null value. Nullable
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
OBJECT_CATALOG	VARCHAR(128)	Relational database name
OBJECT_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the object.
OBJECT_NAME	VARCHAR(128)	Name of the object.
OBJECT_TYPE	VARCHAR(10)	The type of the object: SEQUENCE The object is a sequence. XML SCHEMA The object is an XML schema.
PRIVILEGE_TYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the sequence or XML schema. USAGE The privilege to use the sequence or XML schema.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.

USER_DEFINED_TYPES

The USER_DEFINED_TYPES view contains one row for each distinct type.

The following table describes the columns in the view¹⁶⁶:

Table 270. USER_DEFINED_TYPES view

Column Name	Data Type	Description
USER_DEFINED_TYPE_CATALOG	VARCHAR(128)	Relational database name
USER_DEFINED_TYPE_SCHEMA	VARCHAR(128)	Schema name of the distinct type
USER_DEFINED_TYPE_NAME	VARCHAR(128)	Name of the user that created the distinct type.
USER_DEFINED_TYPE_CATEGORY	VARCHAR(128)	Indicates the type of user-defined type. Contains 'DISTINCT'.
IS_INSTANTIABLE	VARCHAR(3)	Reserved. Contains 'YES'.
IS_FINAL	VARCHAR(3)	Reserved. Contains 'YES'.
ORDERING_FORM	VARCHAR(4)	Indicates what kind of predicates are allowed when this distinct type is a comparand: FULL All predicates are allowed. NONE No predicates are allowed
ORDERING_CATEGORY	VARCHAR(8)	Reserved. Contains 'MAP'.
ORDERING_ROUTINE_CATALOG	VARCHAR(128)	Relational database name
	Nullable	Contains the null value if the ORDERING_FORM is 'NONE'.
ORDERING_ROUTINE_SCHEMA	VARCHAR(128)	Reserved. Contains 'SYSIBM'.
	Nullable	Contains the null value if the ORDERING_FORM is 'NONE'.
ORDERING_ROUTINE_NAME	VARCHAR(128)	Reserved. Contains a data type name.
	Nullable	Contains the null value if the ORDERING_FORM is 'NONE'.
REFERENCE_TYPE	VARCHAR(16)	Reserved. Contains the null value.
	Nullable	

¹⁶⁶ This view does not contain information about built-in data types.

Table 270. USER_DEFINED_TYPES view (continued)

Column Name	Data Type	Description
DATA_TYPE	VARCHAR(128) Nullable	Source data type of the distinct type: BIGINT Big number INTEGER Large number SMALLINT Small number DECIMAL Packed decimal NUMERIC Zoned decimal DOUBLE PRECISION Floating point; DOUBLE PRECISION REAL Floating point; REAL DECFLOAT Decimal floating-point CHARACTER Fixed-length character string CHARACTER VARYING Varying-length character string CHARACTER LARGE OBJECT Character large object string GRAPHIC Fixed-length graphic string GRAPHIC VARYING Varying-length graphic string DOUBLE-BYTE CHARACTER LARGE OBJECT Double-byte character large object string NATIONAL CHARACTER National character NATIONAL CHARACTER VARYING Varying-length national character NATIONAL CHARACTER LARGE OBJECT National character large object BINARY Fixed-length binary string BINARY VARYING Varying-length binary string BINARY LARGE OBJECT Binary large object string DATE Date TIME Time TIMESTAMP Timestamp DATALINK Datalink ROWID Row ID XML XML USER-DEFINED Distinct Type
CHARACTER_MAXIMUM_LENGTH	INTEGER Nullable	Maximum length of the distinct type for binary, character, and graphic string and XML data types. Contains the null value if the distinct type is not a string.
CHARACTER_OCTET_LENGTH	INTEGER Nullable	Number of bytes of the distinct type for binary, character, and graphic string and XML data types. Contains the null value if the distinct type is not a string.

Table 270. USER_DEFINED_TYPES view (continued)

Column Name	Data Type	Description
CHARACTER_SET_CATALOG	VARCHAR(128) Nullable	Relational database name of the distinct type. Contains the null value if the distinct type is not a string.
CHARACTER_SET_SCHEMA	VARCHAR(128) Nullable	The schema name of the character set of the distinct type. Contains 'SYSIBM'. Contains the null value if the distinct type is not a string.
CHARACTER_SET_NAME	VARCHAR(128) Nullable	The character set name of the distinct type. Contains the null value if the distinct type is not a string.
COLLATION_CATALOG	VARCHAR(128) Nullable	Relational database name of the distinct type. Contains the null value if the distinct type is not a string.
COLLATION_SCHEMA	VARCHAR(128) Nullable	The schema of the collation of the distinct type. SYSIBM is returned. Contains the null value if the distinct type is not a string.
COLLATION_NAME	VARCHAR(128) Nullable	The collation name of the distinct type. IBMDEFAULT is returned. Contains the null value if the distinct type is not a string.
NUMERIC_PRECISION	INTEGER Nullable	The precision of the distinct type. Note: This column supplies the precision of all numeric data types, including single-and double-precision floating point and decimal floating-point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if the distinct type is not numeric.
NUMERIC_PRECISION_RADIX	INTEGER Nullable	Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits: 2 Binary; floating-point precision is specified in binary digits. 10 Decimal; all other numeric types are specified in decimal digits. Contains the null value if the distinct type is not numeric.
NUMERIC_SCALE	SMALLINT Nullable	Scale of numeric distinct type. Contains the null value if the distinct type is not decimal, numeric, or binary.
DATETIME_PRECISION	INTEGER Nullable	The fractional part of a date, time, or timestamp distinct type. 0 For DATE and TIME data types 0-12 For TIMESTAMP data types (number of fractional seconds). Contains the null value if the distinct type is not date, time, or timestamp.
INTERVAL_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
INTERVAL_PRECISION	INTEGER Nullable	Reserved. Contains the null value.
SOURCE_DTD_IDENTIFIER	VARCHAR(128) Nullable	A unique internal identifier for the source data type. Contains the null value if the distinct type is not sourced on another distinct type.
REF_DTD_IDENTIFIER	VARCHAR(256) Nullable	Reserved. Contains the null value.
DECLARED_DATA_TYPE	VARCHAR(128) Nullable	Reserved. Contains the null value.
DECLARED_NUMERIC_PRECISION	INTEGER Nullable	Reserved. Contains the null value.

Table 270. *USER_DEFINED_TYPES* view (continued)

Column Name	Data Type	Description
DECLARED_NUMERIC_SCALE	INTEGER Nullable	Reserved. Contains the null value.
MAXIMUM_CARDINALITY	BIGINT Nullable	The maximum cardinality of the array data type. Contains the null value if the type is not an array type.

VARIABLE_PRIVILEGES

The VARIABLE_PRIVILEGES view contains one row for every privilege granted on a global variable. Note that this catalog view cannot be used to determine whether a user is authorized to a global variable because the privilege to use a global variable could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

Table 271. *VARIABLE_PRIVILEGES* view

Column Name	Data Type	Description
GRANTOR	VARCHAR(128) Nullable	Reserved. Contains the null value.
GRANTEE	VARCHAR(128)	The user profile to which the privilege is granted.
VARIABLE_CATALOG	VARCHAR(128)	Relational database name
VARIABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the global variable.
VARIABLE_NAME	VARCHAR(128)	Name of the global variable.
PRIVILEGE_TYPE	VARCHAR(10)	The privilege granted: ALTER The privilege to alter the global variable. READ The privilege to read the value of the global variable. WRITE The privilege to assign a value to the global variable.
IS_GRANTABLE	VARCHAR(3)	Indicates whether the privilege is grantable to other users. NO The privilege is not grantable. YES The privilege is grantable.

VIEWS

The VIEWS view contains one row for each view.

The following table describes the columns in the view:

Table 272. *VIEWS* view

Column Name	Data Type	Description
TABLE_CATALOG	VARCHAR(128)	Relational database name
TABLE_SCHEMA	VARCHAR(128)	Name of the SQL schema that contains the view.
TABLE_NAME	VARCHAR(128)	Name of the view.
VIEW_DEFINITION	DBCLOB(2M) CCSID 13488 Nullable	The query expression portion of the CREATE VIEW statement.

Table 272. VIEWS view (continued)

Column Name	Data Type	Description
CHECK_OPTION	VARCHAR(8)	The check option used on the view NONE No check option was specified LOCAL The local option was specified CASCDED The cascaded option was specified
IS_UPDATABLE	VARCHAR(3)	Specifies if the view is updatable: YES The view is updatable NO The view is read-only

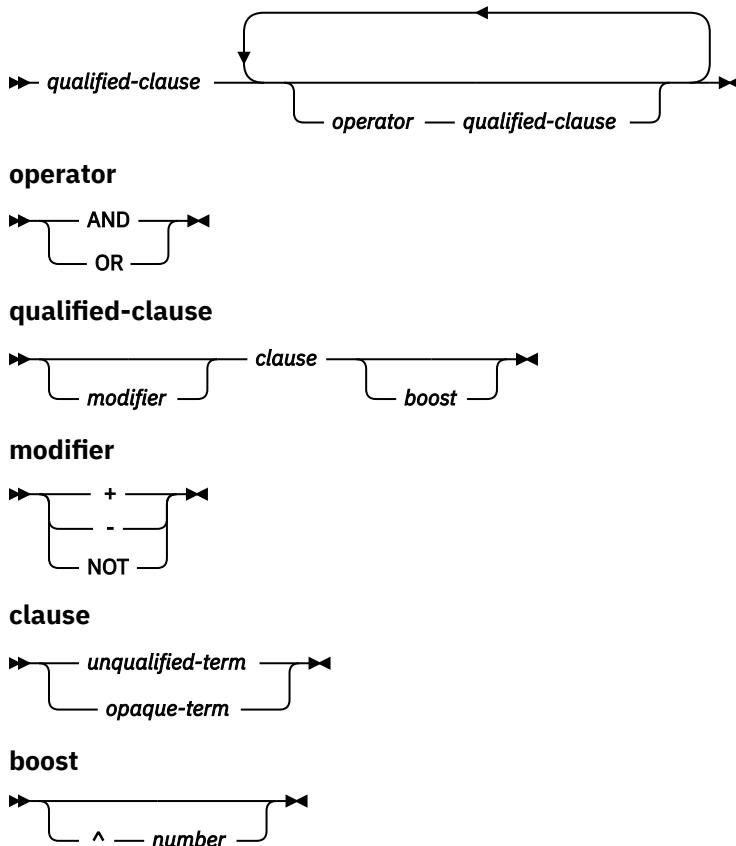

Appendix G. Text search argument syntax

A text search argument is specified when searching for terms in text documents. It consists of search parameters and one or more search terms. The SQL scalar text search functions that use text search arguments are CONTAINS and SCORE.

For information on CONTAINS and SCORE, see “CONTAINS” on page 299 and “SCORE” on page 468.

For more information on text search, see [OmniFind Text Search Server for DB2 for i](#)

Syntax

Description

A search argument is a term or sequence of terms, separated by white space, specified when searching in text documents. It consists of one or more search terms and various optional search parameters.

To perform a simple search, you can enter one or more terms. The search engine returns documents that contain all of those terms or variations of those terms. For example, if you perform a search on the term *king*, documents containing *king* are returned. By default, the search engine also returns variants of the search term. Thus, documents containing *kings* are also returned. Similarly, when you search on two terms, the search engine returns documents containing both terms. If you want the terms to be searched as an exact phrase, simply add quotation marks.

The more specific the search term you use, the more precise the results. However, you may also want to refine your searches by using one or more of the following options:

operator

Specifies whether the search for either or both *qualified clauses* on either side of the *operator* must be satisfied.

AND

The search for both *qualified clauses* on either side of the *operator* must be satisfied.

OR

The search for at least one of the *qualified clauses* on either side of the *operator* must be satisfied.

Similar to search conditions in SQL, parentheses can be used to determine which *qualified clauses* and *operators* are evaluated first. If parentheses are not specified, AND is applied before OR.

modifier

Each *clause* can have an occurrence modifier. If a *modifier* is not specified for a *clause*, the default is plus (+).

+

The *clause* is required in the document.

- or NOT

The *clause* must not be specified in the document.

?

The *clause* is optional in the document.

clause

Specifies a search string. In the search string, the question mark and asterisk have special meanings. Use a question mark (?) to represent any single character, and an asterisk (*) to represent a string of zero or more characters. If the search string contains multiple words that should be treated as a phrase, include quotation marks ("") around the search string. Blanks within a *clause* are ignored.

unqualified-term

An unqualified term is simply a term or a phrase. A term can be a word, such as king; an exact word, such as "king"; or a word that includes a question mark (?) to represent any single character, and an asterisk (*) to represent a string of zero or more characters, such as king* or king?.

Similarly, a phrase can be a group of words, such as cabbages and kings; an exact phrase, such as "The King and I"; or a phrase that includes a wildcard, such as "all the king's ho*ses" or "all the king's ?".

If a character in *clause* is one of the characters that has a special meaning in the syntax of the search argument, an escape character (\) can be used to indicate that the subsequent character should be treated as a regular character in the *clause*.

opaque-term

An opaque query term is so called because it is not parsed by the linguistic query parser; opaque terms are identified by their syntax. The opaque term used for text search queries that include XML markup is @xmlxp:, for example: @xmlxp:'/TagA/TagB[. contains("king")]'

boost

boost can be specified for each *clause*. *boost* provides a higher or lower importance to occurrences of the *clause*.

number

Specifies a decimal or integer constant that is greater than 0. If *boost* is not specified for a *clause*, the default boost value is 1.

Notes

Case sensitivity: Searches are not case sensitive, so a search in Spanish for the exact term "DOS" could return documents containing DOS or dos.

Examples: Simple text search

The CONTAINS and SCORE functions can be used to perform a simple text search for a single word or multiple words in a text search index.

The search engine ignores white space between characters. An empty search argument, or one that contains only blanks, does not match anything.

The following table shows some examples of simple text search requests.

Table 273. Simple text search examples

Search word types	Examples	Search results
Single word	king	Returns all documents that contain the word king or kings. The search is not case-sensitive.
Multiple words	king lear	Returns all documents that contain king and lear. The default operator is the logical operator AND.

The operators AND and + (plus sign) are implicit in every text search. For example, the text search for King Lear returns the same results as King AND Lear or King + Lear.

You must enter the logical operators NOT, AND, and OR in all uppercase.

Advanced text search operators

You can use advanced text search operators to refine the search results for the CONTAINS function and the SCORE function.

In the following table, the first column describes the operator that you can use in a text search. (You must enter the logical operators NOT, AND, and OR in all uppercase letters.) The second column shows a sample text search that you might enter. The third column describes the types of results that you might see from the example text search.

Table 274. Advanced search operators and complex text search examples

Operators	Examples	Search results
AND	"King Lear" AND "Othello" "King Lear" "Othello"	Either text search returns documents that contain both terms King Lear and Othello. The AND operator is the default conjunction operator. If no logical operator is between the two terms, the AND operator is used. For example, the text search King Lear is the same as the text search King AND Lear.
OR	"King Lear" OR Lear	Returns documents that contain either King Lear or just Lear. The OR operator links the two terms and finds a matching document if either of the terms exist in a document.
NOT	"King Lear" NOT "Norman Lear"	Returns documents that contain King Lear but not Norman Lear. The NOT operator cannot be used with only one term. For example, the following search will return no results: NOT "King Lear".

Table 274. Advanced search operators and complex text search examples (continued)

Operators	Examples	Search results
" "	First text search: "King Lear" Second text search: "king"	The first text search returns the exact phrase King Lear. The second text search returns only the word king and no other forms, such as kings or kingly.
*	test* text	Returns documents that can match possible combinations, such as test, tests, and tester, or test and text.
?	test? te?t	Returns documents that can match possible combinations, such as tests, or test and text.
^	First text search: "King Lear"^4 "Richard III" Second text search: title: (software download)^5 pdf viewer -shipping	The first text search forces documents with the phrase King Lear to appear higher in the list of search results. The second text search forces a document titled software download to appear higher in the list of results. Although a boost factor must be positive, the boost factor can be less than 1. For example, 0.2. The boost factor number has no limit.
+	+Lear King	Returns all documents that contain Lear and King, which is the same as the text search Lear AND King.
-	"King Lear" -"Lear Jet"	Returns documents that contain King Lear but not Lear Jet.
()	(King OR Lear) AND plays	Returns documents that contain either King or Lear and plays. The parentheses ensure that plays is found and either term King or Lear is present.
\	\(1\+1\)\:2	Returns documents that contain (1+1):2. Use the \ to clear special characters that are part of the text search syntax. Special characters are + - && ! (){}[] ^ " * ? : \. If a special character is cleared, the special character is analyzed as part of the text search.

Example: Using the CONTAINS function and SCORE function

You can use the CONTAINS function or the SCORE function in the same query to search a text search index and to return if and how frequently the text document matches the search argument criteria.

The example in the following table uses data from the base table BOOKS with the columns ISBN (VARCHAR(20)), ABSTRACT (VARCHAR(10000)), and PRICE (INTEGER).

Table 275. The base table BOOKS

ISBN	ABSTRACT	PRICE
i1	"a b c"	7
i2	"a b d"	10
i3	"a e a"	8

You run the following query:

```
SELECT ISBN, SCORE(ABSTRACT, '"b")  
FROM BOOKS  
WHERE CONTAINS (ABSTRACT, '"b") = 1
```

This query returns the following two rows:

```
i1,    0.3  
i3,    0.4
```

The score values might differ depending on the content of the text column.

XML text search

Based on a subset of the XPath language with extensions for text search, XML text search allows you to index and search XML documents so that structural elements can be used separately or can be combined with free text in queries.

Structural elements are tag names, attribute names, and attribute values.

The following list highlights the key features of XML search:

XML structural search

By including special opaque terms in queries, you can search XML documents for structural elements (tag names, attribute names, and attribute values) and text that is scoped by those elements.

XML query tokenization

Free text in XML query terms is tokenized the same way that text in non-XML query terms is tokenized, except that (nested) opaque terms are not supported. Synonyms, wildcard characters, phrases, and lemmatization are supported.

Numeric values

Predicates that compare attribute values to number, date, or dateTime data types are supported.

Complete match

The = (equal sign) operator with a string argument in a predicate calls for an exact match of all tokens in the string with all tokens in the identified text span. The order is NOT significant.

No UIMA access

Unstructured Information Management Architecture (UIMA) is used for tokenization in XML search, but user-written annotators are not supported.

XML text search grammar

A subset of the XPath language, which is defined by an Extended Backus-Naur Form (EBNF) grammar, is supported by the XML search query parser. Queries that do not conform to the supported grammar are rejected by the query parser, which throws an exception.

The EBNF grammar has been simplified in the following ways by:

- Removing the largest-scale structures for specifying iteration and ranges
- Eliminating filter expressions
- Disallowing absolute pathnames in predicate expressions
- Recognizing only one axis (tag) and only in the forward direction

The following table shows the supported grammar in EBNF notation.

Table 276. Supported query grammar in EBNF notation	
Symbol	Production
XMLQuery ::=	QueryPrefix NameSpaceDeclaration QueryString QueryPrefix QueryString
QueryPrefix ::=	@xmlxp:
QueryString ::=	"" PathExpr ""
PathExpr ::=	RelativePathExpr "/" RelativePathExpr? "//" RelativePathExpr
RelativePathExpr ::=	StepExpr (("/" "//") StepExpr)*
StepExpr ::=	("." AbbrevForwardStep) Predicate?
AbbrevForwardStep ::=	"@"? (QName "*")
Predicate ::=	"[" PredicateExpr "] "
PredicateExpr ::=	Expr PredicateExpr ("and" "or") "(" PredicateExpr ")"
Expr ::=	ComparisonExpr ContainmentExpr
ComparisonExpr ::=	PathExpr ComparisonOp Literal
ComparisonOp ::=	"=" "<" ">" "!=" "<=" ">="
Literal ::=	StringLiteral NumericLiteral DateLiteral
ContainmentExpr ::=	PathExpr "contains" "(" StringLiteral ")" PathExpr "excludes" "(" StringLiteral ")"
StringLiteral ::=	"\\" [^"]* "\\" "" [^"]* ""
DateLiteral ::=	"xs:date(\\" xmlDate \")" "xs:dateTime(\\" xmlDateTime \")"
xmlDate ::=	yyyy"-mm"-dd

Table 276. Supported query grammar in EBNF notation (continued)	
xmlDateTime ::=	yyyy "-" mm "-" dd [T] hh ":" mm ":" ss ". uuuuuu
NameSpaceDeclaration ::=	defaultNameSpace (NameSpacePrefixDeclaration)*
defaultNameSpace ::=	"declare default element namespace " StringLiteral ";"
NameSpacePrefixDeclaration ::=	"declare namespace" NameSpacePrefix "=" StringLiteral ";"
NameSpacePrefix ::=	[^":"]+

For more information about QName, see <http://www.w3.org/TR/REC-xml-names/#NT-QName>.

The following information about XML search queries that use XPath notation might not be obvious from the EBNF grammar notations:

- **Names not normalized:** XML tag and attribute names are not normalized when they are indexed. The names are not changed to lowercase or modified in any way. Case is significant in XML tag and attribute names to get a match. Therefore, the strings that are used for XML tag and attribute names in queries must match exactly the names that appear in the source documents.
- **Free text normalization:** Free text in XML documents (text between tags, not inside a tag itself) and attribute values are normalized before indexing. Text in XML search queries (in *contains* or *excludes* operators, or in strings that are surrounded by quotation marks) is normalized, too. Features such as phrases, synonyms, wildcard characters, and lemmas are supported.
- **Operator precedence:** In XML search predicates, containment operators and comparison operators take precedence over logical operators, and all logical operators have the same precedence. Containment operators are *contains* and *excludes*. Comparison operators are =, !=, <, >, <= and >=. Logical operators are "and" and "or." You can use parentheses to ensure the desired precedence.
- **Semantics:** In XML search predicates, the comparison operators can be applied only to attribute values and not to tags.

Examples: XPath text search

All valid XPath queries that are sent to the XML parser must be written in a subset of the XPath language using opaque terms. Opaque terms are not parsed by the linguistic text search parser.

The text search parser recognizes an opaque term by the syntax that is used in the text search. For example:

```
@xpath: 'query'
```

where *query* is the text shown in the examples in the following table.

Table 277. Examples of valid XPath queries

Query	Description
/sentences	Any document with a top-level tag called <i>sentences</i> .
//sentences	Any document with a tag at any level called <i>sentences</i> .
/sentence/paragraph	Any document with a top-level tag <i>sentence</i> having a direct child tag <i>paragraph</i> .
/sentence/paragraph/	Any document with a top-level tag <i>sentence</i> having a direct child tag <i>paragraph</i> .

Table 277. Examples of valid XPath queries (continued)

Query	Description
/book/@author	Any document with a top-level <i>book</i> tag having an attribute <i>author</i> .
/book//@author	Any document with a top-level <i>book</i> tag having a descendant tag at any level with the attribute <i>author</i> .
/book[@author contains("barnes") and @title = "the lemon table"]	Any document with a top-level <i>book</i> tag with an <i>author</i> attribute containing "barnes" (normalized) and a <i>title</i> attribute that only contains the words "the," "lemon" and "table" (normalized in that order).
/book[@author contains("barnes") and (@title contains("lemon") or @title contains("flaubert"))]	Any document with a top-level <i>book</i> tag with the specified <i>author</i> attribute and either of the two specified <i>title</i> attributes.
/book[@publishDate > xs:date("2000-01-01")]	Top level tag is <i>book</i> and <i>book</i> has an attribute <i>PublishDate</i> that is greater than the date of 2000-01-01.
/book[purchaseTime > xs:dateTime("2009-05-20T13:00:00")]	Top level tag is <i>book</i> . <i>book</i> has a direct child <i>purchaseTime</i> that is a DateTime expression greater than 2009-05-20T13:00:00.
/program[. contains("hello, world.")]	Any document with a top-level <i>program</i> tag containing both the tokens <i>hello</i> and <i>world</i> (normalized) in that order and in consecutive positions.
/book[paragraph contains("foo")]/sentence	Any document with a top-level <i>book</i> tag with a direct child tag <i>paragraph</i> containing "foo" and, referring to the <i>book</i> tag, having a descendant tag <i>sentence</i> at any level.
/auto[@price < 30000.]	Any document with a top-level <i>auto</i> tag having an attribute <i>price</i> with a numeric value that is less than 30000.
//microbe[@size < 3.0e-06]	Any document containing a <i>microbe</i> tag at any level with a <i>size</i> attribute with a value that is less than .000003.

Text search language options

The text search language option specifies which language rules to use when performing a text search.

If QUERYLANGUAGE is not specified, the default is the language value of the text search index that is used when the CONTAINS or SCORE function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US. The following table shows the valid language codes that may be used in the QUERYLANGUAGE option.

Language code	Language
ar_AA	Arabic
cs_CZ	Czech

Language code	Language
da_DK	Danish
de_CH	German (Switzerland)
de_DE	German (Germany)
el_GR	Greek
en_AU	English (Australia)
en_GB	English (United Kingdom)
en_US	English (United States)
es_ES	Spanish (Spain)
fi_FI	Finnish
fr_CA	French (Canada)
fr_FR	French (France)
it_IT	Italian
ja_JP	Japanese
ko_KR	Korean
nb_NO	Norwegian Bokmal
nl_NL	Dutch
nn_NO	Norwegian Nynorsk
pl_PL	Polish
pt_BR	Portuguese (Brazil)
pt_PT	Portuguese (Portugal)
ru_RU	Russian
sv_SE	Swedish
zh_CN	Simplified Chinese
zh_TW	Traditional Chinese

Appendix H. Terminology differences

Some terminology used in the ANSI and ISO standards differs from the terminology used in this book and other product books.

The following table is a cross reference of the SQL 2003 Core standard terms to Db2 SQL

Table 278. ANSI/ISO term to Db2 SQL term cross-reference	
ANSI/ISO Term	Db2 SQL Term
literal	constant
comparison predicate	basic predicate
comparison predicate subquery	subquery in a basic predicate
degree of table/cursor	number of items in a select list
grouped table	result table created by a group-by or having clause
grouped view	result view created by a group-by or having clause
grouping column	column in a group-by clause
outer reference	correlated reference
query expression	fullselect
query specification	subselect
result specification	result
set function	aggregate function
table expression	→ from-clause → where-clause → group-by-clause → having-clause
target specification	host variable followed by an indicator variable
transaction	logical unit of work or unit of work
value expression	arithmetic expression

The following table is a cross reference of Db2 SQL terms to the SQL 2003 Core standard terms.

Table 279. Db2 SQL term to ANSI/ISO term cross-reference

Db2 SQL Term	ANSI/ISO Term
aggregate function	set function
arithmetic expression	value expression
basic predicate	comparison predicate
column in a group-by clause	grouping column
correlated reference	outer reference
→—from-clause—→ →—where-clause—→ →—group-by-clause—→ →—having-clause—→	table expression
fullselect	query expression
host variable followed by an indicator variable	target specification
logical unit of work or unit of work	transaction
interactive SQL	direct SQL
number of items in a select list	degree of table/cursor
result	result specification
result table created by a group-by or having clause	grouped table
result view created by a group-by or having clause	grouped view
subquery in a basic predicate	comparison predicate subquery
subselect	query specification
subselect or fullselect in parenthesis	query term

Appendix I. Reserved schema names and reserved words

This topic describes the restrictions of certain names used by the database manager. In some cases, names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented by the database manager.

Reserved schema names

This is the list of reserved schema names.

The following schema names are reserved:

- QSYS2
- SYSCAT
- SYSFUN
- SYSIBM
- SYSIBMADM
- SYSPROC
- SYSPUBLIC
- SYSSTAT
- SYSTEM
- SYSTOOLS

In addition, it is strongly recommended that schema names never begin with the Q prefix or SYS prefix, as Q and SYS are by convention used to indicate an area reserved by the system.

It is also recommended not to use SESSION as a schema name.

Reserved words

This is the list of currently reserved Db2 for i words.

Words may be added at any time. For a list of additional words that may become reserved in the future, see the IBM SQL and ANSI reserved words in the SQL Reference for Cross-Platform Development (<http://www.ibm.com/developerworks/data/library/techarticle/0206sqlref/0206sqlref.html>).

Table 280. SQL Reserved Words

ABSENT			
ACCORDING	CLUSTER	DBPARTITIONNAME	EXCEPTION

Appendix J. Related information

The publications listed here provide additional information about topics described or referred to in this guide.

These manuals are listed with their full titles and order numbers. When these manuals are referred to in this guide, a shortened version of the title is used.

- Backup and recovery

The manual contains information about planning a backup and recovery strategy, the different types of media available to save and restore procedures, and disk recovery procedures. It also describes how to install the system again from backup.

- ILE COBOL Programmer's Guide 

This guide provides information needed to design, write, test, and maintain COBOL programs on the IBM i products.

- ILE RPG Programmer's Guide 

This guide provides information you need to design, write, test, and maintain ILE RPG programs on the IBM i products.

- REXX/400 Programmer's Guide 

This guide provides information you need to design, write, test, and maintain REXX/400 programs on the IBM i products.

- CL programming

This guide provides a wide-ranging discussion of the programming topics, including a general discussion of objects and libraries, CL programming, controlling flow and communicating between programs, working with objects in CL programs, and creating CL programs. Other topics include predefined and impromptu messages and handling, defining and creating user-defined commands and menus, application testing, including debug mode, breakpoints, traces, and display functions.

- Database file management

This book provides information about using files in application programs.

- Database programming

This book provides a detailed description of the IBM i database organization, including information about how to create, describe, and update database files on the system.

- Distributed database programming

Provides information about preparing and managing an IBM i product in a distributed relational database using the Distributed Relational Database Architecture (DRDA). Describes planning, setting up, programming, administering, and operating a distributed relational database on more than one IBM i product in a like-system environment.

- Security reference

This guide provides information about system security concepts, planning for security, and setting up security on the system. It also gives information about protecting the system and data from being used by people who do not have the proper authorization, protecting the data from intentional or unintentional damage or destruction, keeping security up-to-date, and setting up security on the system.

- SQL programming

This book provides an overview of how to design, write, run, and test Db2 for i statements. It also describes interactive Structured Query Language (SQL).

- [SQL XML programming](#)

This book provides information about using the XML data type with SQL. It includes examples of using functions and procedures to generate XML and to retrieve all or part of an XML document.

- [Embedded SQL programming](#)

This book provides examples of how to write SQL statements in ILE C, ILE C++, COBOL, ILE COBOL, RPG, ILE RPG, REXX, and PL/I programs.

- [Database performance and query optimization](#)

This book provides information about optimizing the performance of your queries using available tools and techniques.

- [IDDU Use](#) 

This book describes how to use IBM i interactive data definition utility (IDDU) to describe data dictionaries, files, and records to the system.

- [SQL call level interfaces \(ODBC\)](#)

This book describes how to use X/Open SQL Call Level Interface to access SQL functions directly through procedure calls to a service program provided by Db2 for i.

- [IBM i Access category in the IBM i Information Center](#)

This information describes how to set up and run ODBC applications on a client using IBM i Access ODBC. Included in this document are chapters on performance, examples, and configuring specific applications to run with IBM i Access ODBC.

- [IBM Toolbox for Java](#)

This book describes how to set up and run JDBC applications on a client using IBM Toolbox for Java. Included in this document are chapters on performance, examples, and configuring specific applications to run with IBM Toolbox for Java.

- [IBM Developer Kit for Java](#)

This information provides the details you need to design, write, test, and maintain JAVA programs on the IBM i product. The book also contains information about the IBM Developer Kit for Java JDBC driver.

- [DB2 Multisystem](#)

This book describes the fundamental concepts of distributed relational database files, nodegroups, and partitioning. The book provides the information you need to create and use database files that are partitioned across multiple systems. Information is provided on how to configure the systems, how to create the files, and how the files can be used in applications.

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
1623-14, Shimotsuruma, Yamato-shi
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation
Software Interoperability Coordinator, Department YBWA
3605 Highway 52 N
Rochester, MN 55901
U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.
